For reasons of health, Colonel Le Bel, physician in chief of the Canadian hospital at Saint-Cloud, has left France to return to Quebec. As an evidence of the recognition of France for the services rendered by the colonel to the French wounded, M. Justin Godart, the undersecretary of state for the army medical department, has conferred on him the cross of an officer of the Legion of Honor.

LONDON LETTER

London, Nov. 6, 1917.

The War

WAR BREAD

In certain cases of disease, the government grants permits for the use of white flour; but the applications are becoming so numerous, and the necessity for economizing wheat so imperative, that it is not possible to accede to all of them. A medical subcommittee has been appointed by the Ministry of Food to deal with such cases. It finds in many cases no substantial grounds for the applications, which appear to be made merely to satisfy some whim of the patient and not because the government regulation flour has been found to be deleterious. Speaking generally, it may be said that unless some affection of the digestive organs is present which, in the opinion of the War Bread Medical Subcommittee, justifies the use of pure wheaten flour, an application cannot be granted. Thus, for instance, in acute affections of the stomach (acute gastric catarrh, ulcer in its acute stages, etc.), the use of any form of bread while the disease is at its height is probably inadmissible. During the convalescent stages the prescription of pure wheaten flour for a limited period may be permissible if rusks and breakfast biscuits or ordinary bread boiled and sieved, or bread jelly, do not meet the case. In chronic functional disorders of the stomach (which make up the majority of cases of chronic dyspepsia), the use of pure wheaten flour can rarely be allowed, for the reason that such cases are so numerous and so protracted in their course that it would be impossible to meet demands without seriously depleting the wheat supply of the rest of the population. The use of the present bread, well toasted and thoroughly chewed, or of biscuits and rusks, is recommended. In chronic organic disease of the stomach (carcinoma and chronic ulcer), white flour may sometimes be advisable, if the patient is able to take bread at all. In acute affections of the intestine (acute diarrhea, enteritis, colitis, ulcerative conditions, etc.), the same remark applies as in acute affections of the stomach. In chronic intestinal affections (chronic diarrhea, chronic colitis, malignant disease, etc.), the use of white flour may be desirable; but evidence is required to show that ordinary bread, toasted and thoroughly chewed, and the use of other measures, have failed to relieve the symptoms. Cases of disease of the nervous, circulatory or respiratory systems, or the urinary organs or skin, or such general conditions as anemia and diabetes, are considered rarely suitable for grants. As regards tuberculosis, there is no evidence that the war bread is injurious.

THE CONTROL OF VENEREAL DISEASES

The problem of the control of venereal diseases is receiving
a good deal of attention both at home and in our dominions
beyond the seas. The National Council for Combating
Venereal Diseases (a philanthropic body formed for this
object) has adopted a resolution in which it refrains from
recommending prophylaxis in the form of provision of outfits
to men before sexual indulgence. At the same time it urges
the importance of making arrangements for early treatment
before the onset of symptoms. The Local Government Board
has sent to the councils of counties and county boroughs in England and Wales a circular calling attention to putting into force the Venereal Disease Act. The purpose of the act is to prevent the treatment of venereal disease otherwise than by duly qualified physicians, and to control the supply of remedies therefor. The necessity for such a measure is shown by the report of the Royal Commission of Venereal Diseases, which stated that the continued existence of unqualified practice constitutes one of the principal hindrances to the eradication of those diseases. The act renders it illegal for any one other than a duly qualified physician for reward, either direct or indirect, to treat any person for venereal disease, or prescribe any remedy for such disease, or give any advice in connection with the treatment thereof, whether the advice is given to the person to be treated or to any other person. But this prohibition does not come into operation within any area until a scheme for the gratuitous treatment of persons in that area suffering from venereal disease has been approved by the board and is already in operation. The act prohibits advertisements, public notices and announcements (other than advertisements, notices or announcements published by any local or public authority or with the sanction of the board, or publications sent only to duly qualified physicians or to wholesale or retail chemists for the purposes of their business) with respect to the treatment of venereal disease or the prescription of remedies therefor, or the giving of advice in connection with the treatment. The act also prohibits the advertisement or recommendation to the public of any so-called remedies for venereal disease by means of any printed papers or handbills, or by labels, etc., affixed to or delivered with any packet, bottle, etc., containing any such so-called remedies.

The Federal Committee of the British Medical Association is asking the state governments in New South Wales and in South Australia to pass a venereal diseases act on similar lines to the acts of the other states of the commonwealth described in the previous letter to The Journal. This committee is divided in opinion on the question of the advisability of making more widely known precautions for the prevention of venereal diseases that may be taken by those who have exposed themselves to the risk of infection. In Queensland and in Western Australia, physicians have not reported anything approaching the number of cases of venereal disease that must have occurred. The defense department in Australia has given facilities to civil practitioners to obtain special experience in the treatment of venereal disease by attendance at military venereal disease hospitals and camps. In Queensland the health amending act, 1917, gives the commissioner, instead of the governor-in-council, power to make regulations for the treatment of venereal diseases and for the establishment, management and control of dispensaries or other places for gratuitous treatment. No one must treat venereal diseases except a physician; but the commissioner may grant a permit to a pharmacist to prescribe if a physician is not available. In South Australia, the government is well satisfied with the night clinics for venereal disease. In Victoria the minister of health is appointing a venereal diseases advisory committee to assist in administering the Venereal Diseases Act. The sale by pharmacists of any "patent" or proprietary medicine specially recommended is prohibited for the treatment of any venereal disease. The following are specifically mentioned: hydrargyrum cum creta or its admixtures; red mercuric iodid; mercury tannate; mercuric cyanid in pill or tablet form; sandalwood oil or its derivatives; copaiba or its derivatives, in the form of emulsion or capsules; kharsivan (British salvarsan); argyrol; gray oil or similar mercurial emulsions; methylene blue in pills, tablets or capsules; medicated bougies, and gonococcus vaccines and serums. Every person suffering from venereal disease or suspected of so suffering must consult at regular intervals a physician, who shall deliver a warning notice of the penalties involved, and a booklet issued by the public health department, "Information Relating to Venereal Diseases." No person suffering from venereal disease shall carry, deliver, manufacture, prepare, or otherwise handle food intended for consumption by any other person. Precautions must be observed by individuals in the care of children.

The Medical Service of the Australasian forces in Egypt has established a prophylactic tent at the entrance of each camp where men who have exposed themselves to infection can be disinfected. These disinfections have been so successful that in a series of 2,000 cases only three men developed disease. In the first month after the introduction of the system, of 432 men who were treated, not one developed disease, while of thirty-five men who developed disease, not one visited the tent.

Deaths

Major Richard Weil, M. R. C., U. S. Army, New York City; College of Physicians and Surgeons in the City of New York, 1900; aged 41; died in the base hospital at Camp Joseph Wheeler, Macon, Ga., November 19, from *pneumonia*. Dr. Weil was one of the recognized leaders in American cancer research. He was a Fellow of the American Medical Association, and a member of the American Association of Pathology and Bacteriology; he was also visiting physician to Mount Sinai Hospital, and the Montefiore Home, New York City. Since 1906, Dr. Weil had been an active member of the Huntington Fund, and constantly engaged in the problems of cancer research. His contributions in the field of serology of cancer and in the general problems of immunity have gained for him an international reputation; he was one of the founders of the American Association of Cancer Research, and was one of the founders and editor-in-chief of the *Journal of Cancer Research*. At the reorganization of the Memorial Hospital in 1913, Dr. Weil became assistant director in cancer research and attending physician to the hospital, and labored energetically to establish an efficient and routine work of the institution. On his appointment as professor of experimental medicine in Cornell University in 1915, he resigned as assistant director of the Memorial Hospital, but continued without interruption his experimental work in cancer. On the declaration of war, he was one of the first to offer his services to the government, and spent the summer at the Medical Officers Training Camp, Fort Benjamin Harrison, Ind., and only a short time ago was detailed as chief of the medical staff of the base hospital at Camp Joseph Wheeler, Macon, Ga., and there he died. At a meeting of the board of trustees of the Memorial Hospital, resolutions were adopted setting forth the attainments of Major Weil, and closing with the following paragraph: "During his brief but brilliant carrer he attained eminence as a devoted laboratory worker, a skilful experimenter, a broadly trained clinician, and a forceful writer, while his untimely death places his name among the first on his Country's honor roll in the Great War."

Lieut. Orlando M. Gochnaur, M. R. C., U. S. Army

Lieut. Orlando Merrill Gochnaur, M. R. C., U. S. Army, Freeport, Ill.; College of Physicians and Surgeons, Chicago, 1915; intern in the Calumet and Hecla Hospital, Calumet, Mich., and later in the Henrotin Memorial Hospital, Chicago; who went to France in September, and was on duty with the British forces in Flanders, is reported to have been killed in action, November 6.

Franklin Paine Mall, M.D., Baltimore; University of Michigan, Ann Arbor, 1883; aged 55; a member of the American Association of Anatomy; a fellow in 1886-1888, and instructor in pathology, 1888-1889, in Johns Hopkins University; adjunct professor of vertebrate anatomy in Clark University, Worcester, Mass., in 1889-1892; professor of anatomy in the University of Chicago, 1892-1893, and since that time professor of anatomy in Johns Hopkins University; who was made director of the Department of Embryology in the Carnegie Institution, Washington, D. C., in 1915; a distinguished anatomist, and a member of many learned societies; a prolific contributor to the literature of his specialty; joint editor of the *Handbuch der Entwicklungsgeschichte des Menschen;* co-editor and one of the founders of the *American Journal of Anatomy* and the *Anatomical Record;* associate editor of the *Journal of Morphology*, and editor of *Studies from the Anatomical Laboratory of Johns Hopkins University;* died in Johns Hopkins Hospital, Baltimore, November 17, after a surgical operation.

James Henry Honan, M.D., Augusta, Ga.; Rush Medical College, 1895; Royal University, Berlin, Germany, 1897; aged 58; an honorary Fellow of the American Medical Association; a specialist in cardiovascular diseases, and from 1909 until the outbreak of the war a practitioner of Berlin and Bad-Nauheim; professor of diseases of the heart and circulatory system in the University of Georgia, Augusta; formerly local surgeon of the Erie Railway; author of a Hand Book of Medical Europe, and a number of treatises on cardiovascular conditions; died at his home, November 11. As a tribute of respect to his memory the Medical College of the University of Georgia was closed on Wednesday, November 14, and the faculty attended the funeral in a body.

Francis LeRoy Satterlee, M.D., New York City; New York University, New York City, 1868; aged 70; a Fellow of the American Medical Association, and New York Academy of Medicine, and a member of the New York Pathological Society; professor of chemistry, materia medica and therapeutics in the New York College of Dentistry since 1869; lecturer on agricultural chemistry and hygiene in the New York College of Veterinary Surgery since 1870; lecturer on physiology and hygiene in his alma mater; for many years major and surgeon of the Eighty-Fourth Infantry, N. G., N. Y., and for eighteen years surgeon to the New York Police Department; attending physician to St. Elizabeth's Hospital; died at his home, November 12, from heart disease.

William Keener Sutherlin, M.D., Shreveport, La.; New York University, New York City, 1881; Kaiser Wilhelm University, Berlin, Germany, 1897; aged 58; formerly a Fellow of the American Medical Association, and once vice president of the Louisiana State Medical Association; a well-known surgeon, and proprietor of Sutherlin's Sanatorium, Shreveport; died in the Schumpert Sanitarium, Shreveport, November 10, from pneumonia.

William Boardman Reed, M.D., Alhambra, Calif., University of Pennsylvania, Philadelphia, 1878; aged 75; formerly a Fellow of the American Medical Association; a veteran of the Civil War, and a well known specialist on diseases of the digestive system; for many years a resident of Atlantic City, N. J.; at one time a member of the editorial staff of the Philadelphia *Press;* who went to California on account of ill health in 1909, and suffered a cerebral hemorrhage in 1913; died at his home, October 31.

John Zebulon Currie, M.D., Cambridge, Mass.; Harvard Medical School, 1873; University of Edinburgh, Scotland, 1874; aged 70; a Fellow of the American Medical Association; physician to the New England Baptist Home for Aged People; died suddenly, from heart disease, November 11, while in his automobile in East Arlington, Mass.

Mary O'Brien Porter, M.D., Chicago; Kansas Medical College, Topeka, 1899; Northwestern University Woman's Medical School, Chicago, 1901; aged 47; a member of the Illinois State Medical Society, and a member of the staff of the Psychopathic Laboratory for the Municipal Courts; died at her home, November 18, from pneumonia.

Thomas Howard Marable, M.D., Clarksville, Tenn.; New York University, New York City, 1878; aged 61; a Fellow of the American Medical Association; mayor of Clarksville;

president of the Tennessee State Medical Association, 1898, and of the Clarksville Academy of Medicine from 1891 to 1893; a specialist in obstetrics; professor of obstetrics in the University of Tennessee, Nashville; died at his home, November 12.

William Gibson Craig, M.D., Springfield, Mass.; Jefferson Medical College, 1892; aged 49; a Fellow of the American Medical Association, and a member of the American Ophthalmological Association; a specialist on diseases of the eye and ear; ophthalmic and aural surgeon to Mercy Hospital, Springfield; died at his home, November 15.

Burrell A. Fletcher, M.D., Augusta, Ark.; Bellevue Hospital Medical College, 1884; aged 55; formerly a Fellow of the American Medical Association; a member of the Arkansas Medical Society, and president of the Arkansas State Board of Health; died in St. Joseph's Hospital, Memphis, Tenn., November 15.

Ira F. Gose, M.D., Eureka, Utah; College of Physicians and Surgeons, Baltimore, 1896; aged 44; formerly a member of the American Medical Association; who was injured when his automobile overturned near Santaquin, November 10; died from his injuries in the Provo (Utah) General Hospital, November 12.

William E. Henkel, M.D., Hammond, La.; Louisville (Ky.) Medical College, 1885; aged 66; formerly local surgeon of the Illinois Central Railroad; died at his home, November 9, from the effects of a gunshot wound of the breast, self-inflicted two days before, it is believed, with suicidal intent, while despondent.

Ansel Jerome Robbins, M.D., McAlester, Okla.; Georgetown University, Washington, D. C., 1891; Southern Homeopathic Medical College, Baltimore, 1896; aged 58; formerly a member of the Arkansas Medical Society, and a resident of Mena, Ark.; died at his home, September 10, from acute gastritis.

William B. Sutherland, M.D., Loveland, Colo.; College of Physicians and Surgeons, Keokuk, Iowa, 1876; aged 66; formerly a Fellow of the American Medical Association; founder of the first hospital in Larimer County, Colo.; died at his home, November 14, from carcinoma of the stomach.

Claude Watson, M.D., Nebraska City, Neb.; Missouri Medical College, St. Louis, 1877; aged 62; a Fellow of the American Medical Association; for twenty years president of the board of education; died, November 16, from heart disease, while making a professional call near Dunbar, Neb.

Alvin Roy Peebles, M.D., Boulder, Colo.; University of Michigan, Ann Arbor, 1906; aged 33; a Fellow of the American Medical Association; professor of preventive and experimental medicine and director of clinical laboratories in the University of Colorado, Boulder; died, October 22.

Jason T. Wallace, M.D., Oneida, N. Y.; New York Homeopathic Medical College, New York City, 1865; aged 81; a member of the first board of education and of the board of health of Oneida; died at the home of his daughter in that city, November 16, from heart disease.

Jacob Cullen Barr, M.D., Keokuk, Iowa; Medical College of Ohio, 1857; aged 87; formerly a member of the Illinois State Medical Society; major and surgeon of the First Ohio Infantry throughout the Civil War; died at his home, November 13, from cerebral hemorrhage.

Jesse D. Elliott, M.D., Hawleyville, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1882; aged 65; a member of the Iowa State Medical Society; for one term a member of the state senate; died in a hospital in Moline, Ill., November 11, from malignant disease.

Julius M. Wilhelm, M.D., Traverse City, Mich.; University of Pennsylvania, Philadelphia, 1895; aged 55; a Fellow of the American Medical Association; a veteran of the war with Spain; local surgeon for the Pere Marquette Railroad; died at his home, November 14.

Frank M. Winchester, M.D., Charlotte, N. C.; Jefferson Medical College, 1883; aged 60; formerly a Fellow of the American Medical Association; professor of obstetrics in the North Carolina Medical College, Charlotte; died at his home, November 11.

Frank Blair Lovell, M.D., Gibson City, Ill.; Rush Medical College, 1888; Bellevue Hospital Medical College, 1893; aged 51; a Fellow of the American Medical Association; died in the Presbyterian Hospital, Chicago, November 11, from typhoid fever.

Frank Henry Columbus Zornow, M.D., Pittsford, N. Y.; New York Homeopathic Medical College; New York City, 1917; aged 24; an intern in the Rochester (N. Y.) Homeopathic Hospital; died in that institution, October 25, from diphtheria.

William Fletcher Jolley, M.D., Troupsburg, N. Y.; Eclectic Medical College of Pennsylvania, Philadelphia, 1869; aged 69; a member of the Medical Society of the State of New York; died in the Canandaigua (N. Y.) Health Home, November 8.

Harrison Gabel, M.D., Centerville, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1880; aged 76; formerly a member of the Indiana State Medical Association; died at his home, November 15, from valvular heart disease.

George Edward Turrill, M.D., Cleveland; Homeopathic Hospital College, Cleveland, 1879; aged 63; at one time a member of the staff of the Huron Road Hospital, Cleveland; died at his home, November 13, from cerebral hemorrhage.

William Henry Harrison Asbury, M.D., Clay City, Ind.; Medical College of Ohio, Cincinnati, 1875; aged 77; died in the Post-Graduate Hospital, Chicago, November 11, from hemorrhage, six weeks after operation for prostatectomy.

Louis Charles Winternitz, Baltimore (license, Maryland); a practitioner for fifty-two years; aged 74; formerly a Fellow of the American Medical Association; died at his home in Walbrook, Baltimore, November 9, from senile debility.

Malcolm Stewart, M.D., Tesumseh, Neb.; State University of Iowa, Iowa City, 1884; aged 59; a Fellow of the American Medical Association and a specialist in diseases of the eye, ear, nose and throat; died at his home, November 14.

Marriages

Lieut. Norman Zolla, M. C., Ill. N. G., assigned to One Hundred and Thirty-First Field Hospital Company, Camp Logan, Houston, Texas, to Miss Mary McGinty of Chicago, November 11.

Capt. George Davidson McLean, M. R. C., U. S. Army, Oklahoma City, to Miss Ruth Elizabeth Barnes, also of Oklahoma City, October 21.

Lieut. Harold Bartlett Johnson, M. R. C., U. S. Army, to Miss Maxine Crockett of Nashville, Tenn., in Chattanooga, Tenn., November 3.

Edward R. M. Pennypacker, M.D., Scranton, Pa., to Mrs. Vilette Windett Overly, formerly of Chicago, at Salt Lake City, recently.

Lieut. Stanley Edward Straube, M. R. C., U. S. Army, Fort Oglethorpe, Ga., to Miss Sarah Rollow of Edgoten, Ky., recently.

Lieut. Richard Samuel Magee, M. R. C., U. S. Army, to Miss S. Marguerite Bancroft, both of Altoona, Pa., November 16.

William Howard Eister, M.D., Sunbury, Pa., to Miss Amelia Kublic of Sagon, Pa., at Shamokin, Pa., November 7.

Arthur Franklin Wolford, M.D., Chicago, to Miss Nadine Wiley of Moberly, Mo., at Chicago, November 7.

Lieut. Albro L. Parsons, M. R. C., U. S. Army, to Miss Katherine Barnett, both of Louisville, Ky., November 20.

Samuel Shelton Watkins, M.D., Baltimore, to Miss Mary Townsend of Bowling Green, Ky., November 10.

Wilbur Arthur Baker, M.D., Kansas City, Mo., to Miss Olivia Olsson of Lawrence, Kan., November 3.

Floyd Owen Woodward, M.D., to Miss Alice Margaret Hewson, both of Minneapolis, November 14.

Daniel Clark Brennan, M.D., to Miss Josephine Agnes Winum, both of Akron, Ohio, November 6.

Richards Ellison Amos, M.D., Akron, Ohio, to Miss Hazel McCauley of Ironton, Ohio, November 10.

Benoni Austin Place, M.D., Great Falls, Mont., to Miss Margaret Powell of Clarion, Pa., recently.

Oscar Walter Rest, M.D., Chicago, to Miss Dora Lucile Lake of Madison, Wis., November 21.

Alfred Moore, M.D., to Miss Eva McCleskey, both of Memphis, Tenn., November 21.

James F. Gard, M.D., to Mrs. Sarah A. Mooney, both of Carthage, Mo., November 7.

Karl Albert Meyer, M.D., to Miss Faye Hart, both of Chicago, November 11.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

SOME MISBRANDED MINERAL WATERS

Baldwin Cayuga Mineral Water.—Lucius Baldwin & Son, Cayuga, N. Y., shipped in interstate commerce 60 half-gallon bottles of Baldwin Cayuga Mineral Water. The label claimed that the water was a cure for Bright's disease, diabetes, all kidney afflictions, liver complaints, dyspepsia, all affections of the bladder, all forms of rheumatism and all skin diseases besides being a "Wonderful Tonic for General Debility." These claims the government held were false and fraudulent, and furthermore declared the water was adulterated because "it consisted in whole or in part of a filthy, putrid or decomposed substance." Lucius Baldwin & Son, claimants, consented to a decree, and judgment of condemnation and forfeiture was entered and the court ordered that the water should be destroyed.—[*Notice of Judgment No. 4894.*]

Bowden Lithia Water.—The Bowden Lithia Springs Water Co., an Atlanta, Ga., corporation, shipped a quantity of "Bowden Lithia Water" which was misbranded. Analysis showed this product to be another one of the so-called lithia waters containing practically no lithium. The company pleaded guilty and was fined $50.—[*Notice of Judgment No. 4319.*]

Carbonated Colfax Mineral Water.—The federal authorities filed a libel for the seizure and condemnation of 1,200 bottles of mineral water consigned by D. C. Fry & Co., Inc., Colfax, Iowa. The officials charged that the water was adulterated, as chemical and bacteriologic examination showed it to be polluted and containing excessive numbers of bacteria. It was declared misbranded, first, because it was called a "carbonated" water when, as a matter of fact, it was artificially carbonated and, second, because the following false and fraudulent claims were made regarding its alleged curative value:

> "This water is an infallible remedy for all diseases of the liver, kidneys, and blood. It cures constipation and is the most pleasant and certain promoter of digestion known. Nature's remedy for the cure of every form of indigestion or dyspepsia and acute and chronic rheumatism and now acknowledged to be the most wonderful specific for kidney affections yet discovered."

The government declared that the water contained no ingredients or combination of ingredients capable of producing such therapeutic effects. D. C. Fry & Co., Inc., appeared as claimant and, having interposed no objection to a decree, judgment of condemnation and forfeiture was entered, and the court ordered that the water should be destroyed, that the cases and bottles should be returned to the claimant and that the claimant should pay the costs of the proceedings.—[*Notice of Judgment No. 4888.*]

Chippewa Natural Spring Water.—The government filed a libel for the seizure and condemnation of 3,420 bottles, each containing one-half gallon of "Chippewa Natural Spring Water," sold by the Chippewa Springs Corporation, Chippewa Falls, Wis., charging that the product was misbranded. The label declared in part that this matter was "Beneficial and Remedial in cases of Typhoid Fever, Kidney Diseases, Rheumatism, Gout, Constipation, Indigestion, Headache, etc." These claims the government declared were "feloniously and fraudulently made with the intention to create the impression that the article was efficacious for the treatment of the diseases mentioned, whereas, it contained no ingredient or combination of ingredients capable of producing the therapeutic effects claimed." No claimant appeared for the property and the court entered judgment of condemnation and forfeiture, and ordered that the product should be redelivered to the Chippewa Springs Co., on payment of all the costs of the proceedings and the execution of a bond in the sum of $50.—[*Notice of Judgment No. 4726.*]

Crazy Mineral Water.—One hundred and twenty half-gallon bottles of a water labeled "Crazy No. 3" were declared adulterated by the federal authorities. According to the officials this water which, according to the label, was the product of the Crazy Well Water Company, Mineral Wells, Texas, was adulterated because it contained a filthy, decomposed and putrid animal substance. No claimant appeared, and judgment of condemnation and forfeiture was entered and the court ordered that the product should be destroyed.—[*Notice of Judgment No. 4234.*]

Crystal Lithium Springs Water.—George W. Hamilton, who did business as the Crystal Lithia Water Co., Excelsior Springs, Mo., shipped in interstate commerce a quantity of "Crystal Lithium Spring Water," which was declared adulterated and misbranded. Misbranding was alleged because the label claimed that each gallon of the water contained over 2 grains of lithium chlorid when, as a matter of fact, it contained little, if any, lithium chlorid. Further, the claim that the product was the "Best Water in the Treatment of Bright's Disease, Diabetes . . . Rheumatism and Gravel" was declared recklessly and wantonly false and fraudulent. Adulteration was charged in that the product contained filthy, decomposed and putrid animal or vegetable matter. Hamilton pleaded guilty and was fined $100 and costs.—[*Notice of Judgment No. 4174.*]

Gray Mineral Water.—William Baird and William A. Baird, trading as William Baird & Son, Cambridge Springs, Pa., shipped in interstate commerce a quantity of Gray Mineral Water which the federal authorities declared misbranded. The statement on the label that this product was "Nature's Own Cure" for all diseases of the stomach, liver, bowels and urinary organs, also rheumatism, neuralgia, nervous disorders, etc., was declared false and fraudulent and made in reckless and wanton disregard of its truth or falsity. It was further charged that the claims that Gray Mineral Water was "America's choicest table water unequaled in its crystal clearness, pleasant taste and absolute purity" were false and misleading in that they indicated that the product was a natural mineral water when in fact it was an artificially carbonated mineral water. The government charged further that the claim that the product was "bottled at the Spring" was false and misleading because it indicated that the article was bottled at Gray Mineral Spring when in fact it was not. Finally, misbranding was alleged for the further reason that the quantity of the contents was not plainly and conspicuously marked on the outside of the package. The defendants pleaded guilty and were fined $20 and costs.—[*Notice of Judgment No. 4733.*]

Henk Waukesha Mineral Spring Water.—The Henk Mineral Spring Co., Waukesha, Wis., was the trade name under which Margaret K., Arthur W., Emma, Clarence E. and Mabel Henk operated as co-partners in the sale of "Henk Waukesha Mineral Spring Water." The federal authorities proceeded against these individuals on the ground that their product was misbranded. The government held that the claim that Henk Waukesha Mineral Spring Water "is a most effective remedy for all kidney ailments, Bright's disease in its incipiency" was false and fraudulent and made knowingly and in reckless and wanton disregard of its truth or falsity, because in truth and in fact the water did not contain ingredients or medicinal agents effective as a remedy for all kidney ailments or as a remedy for Bright's disease in its incipiency or at any stage. The defendants pleaded guilty and each was fined $25, making an aggregate of $125.—[*Notice of Judgment No. 4858.*]

Seawright Magnesian Lithia Water.—A libel was filed for the seizure and condemnation of 1,656 bottles of "Seawright Magnesian Lithia Water" which were labeled in part "Seawright Magnesian Lithia Spring Co., Nature's Nervine. E. R. Edmondson, manager, Staunton, Va." Misbranding was alleged. The following therapeutic claims appeared on the bottle:

> "Quiets the nerves and induces sleep. Invaluable in all diseases of the Stomach, Liver or Kidneys, Stone in the Bladder, etc. Relieves Dyspepsia, Constipation, Rheumatism, Gout, etc. A sure remedy for Eruptions and all Diseases of the Skin, Ulcerated Stomach, Sore Eyes, etc."

Misbranding was alleged, first, in that the water did not contain enough lithium to entitle it to be designated as a lithia water; second, it "did not contain any ingredients or combination of ingredients capable of producing the therapeutic effects claimed for it." No claimant having appeared, judgment of condemnation and forfeiture was entered and the court ordered that the product should be destroyed.—[*Notice of Judgment No. 3714.*]

White Stone Lithia Water.—Lloyd C. Dillard of Spartanburg, S. C., the Bank of Spartanburg, the Merchants and Farmers' Bank and the First National Bank were charged by the federal authorities with shipping in violation of the Food and Drugs Act "White Stone Lithia Water" which was misbranded. The charge was based on the fact that the name indicated to the purchaser that the product was lithia water when in fact it was not. Moreover, the label represented that it was a cure for all liver, kidney and bladder troubles, rheumatism, gout, all blood diseases and indigestion. These claims the government declared false and fraudulent. L. C. Dillard, the Bank of Spartanburg, the Merchants and Farmers' Bank and the First National Bank pleaded guilty and the court imposed a fine of $10—or $2.50 each.—[*Notice of Judgment No. 4869.*]

Witter Springs Water.—The government filed a libel for the seizure and condemnation of 324 bottles of Witter Springs Water of the Witter Medicinal Springs, San Francisco, Calif. The officials charged that the water was adulterated in that it consisted in whole or in part of a filthy, decomposed and putrid animal or vegetable substance. No claimant appeared and it was adjudged condemned and forfeited and the court ordered that the product should be destroyed.—[*Notice of Judgment No. 4296.*]

Correspondence

CORNEAL TATTOOING

To the Editor:—The Journal has recently published two contributions on corneal tattooing. It seems to me that almost ideal results can be obtained by a modified Froehlich method, which I have followed in several cases. A von Hippel trephine is used to outline the area to be stained, cutting only through the epithelium and upper lamellae of the cornea. With a keratome this is carefully dissected loose, leaving the flap hanging at one side by a small hinge of tissue. The India or Chinese ink emulsion, worked up in a mercuric chlorid solution, is now applied and the flap turned back in place. A beautiful black round pupil remains. If the operation is performed in this manner, the stain is permanent, as can be shown in a case in which it was done six years ago. Dr. Allport's method is very similar excepting for his failure to replace the epithelium, which protects the color more strongly.

Jesse S. Wyler, M.D., Cincinnati.

LOCALIZATION OF FOREIGN BODIES

To the Editor:—In The Journal, Nov. 3, 1917, p. 1521, Dr. Sinclair Tousey details a method of localization of foreign bodies. On account of his prominence as an author, Dr. Tousey having written a very valuable compilation on the roentgen ray, I think that it is unsafe to let the article referred to pass without question.

Dr. Tousey states that by means of a grating laid on the plate, which merely serves the purpose of a scale for the measurement of the displacement of the shadow cast by a foreign body when the source of illumination casting the shadow is moved, the tube being placed at a distance from the plate of 21 inches and the tube shift of 3 inches being employed, he is able to read from the plate without calculation the actual distance of the foreign body casting a shadow from the surface of the plate.

He further states that a shadow traverse of 1/7 inch with tube at 21 inches and tube shift at 3 inches is equal to ½ inch distance from plate to foreign body; that for each additional 1/7 inch shadow traverse an additional ½ inch should be added to this height or depth according as the tube is over or under the patient. This statement is true when the foreign body keeps such a position that its traverse is exactly 3 inches, and under those circumstances it will be *found to be* exactly midway between the anode of the tube and the surface of the plate. In such circumstances the relation is true because two right angled triangles whose elevations are equal must have equal bases. It is not true for any other position of a foreign body, and the error in such circumstances is enormous.

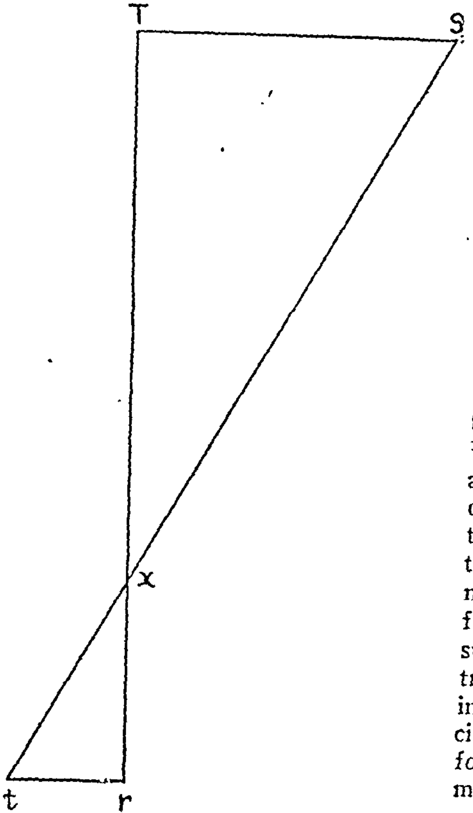

Fig. 1.—Relation of traverses: *TS*, tube traverse; *tr*, traverse of foreign body; *Tr*, anodal plate distance; *xr*, height of foreign body.

$$TS:tr::Tr-xr:xr$$

COMPARISON IN INCHES

Foreign Body Traverse	Depth	
	Tousey	Actual
1/7	0.5	0.9
3/7	1.5	2.6
1	3.5	5.25
1 3/7	5.0	6.7
2	7	8.4
3	10.5	10.5
4	14.0	12.5

Dr. Tousey assumes that the relations here represented may be shown by a simple arithmetical progression, and that if a graph were constructed having foreign body shadow traverse as ordinates, and depth of body in the tissue as abscissas, the relation curve would be a straight line. It

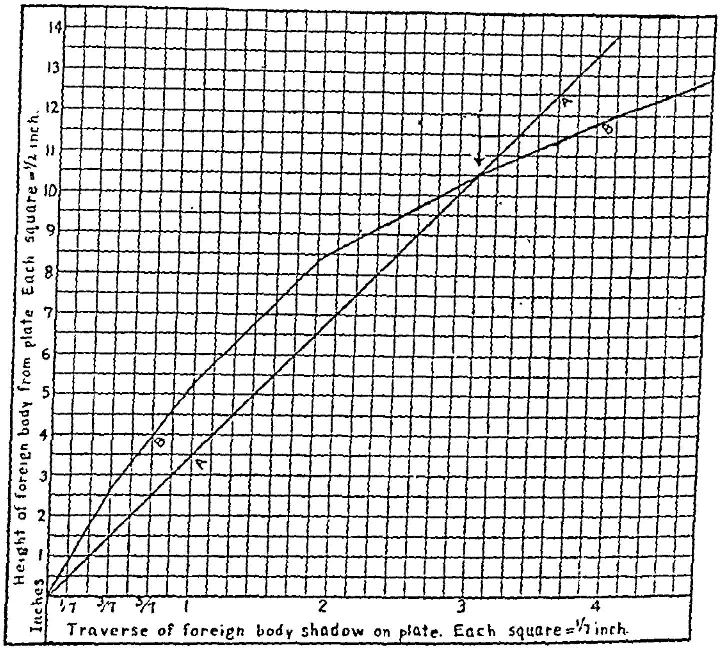

Fig 2.—Comparison of graphs: *A*, Tousey's curve; *B*, actual curve; arrow indicates point at which Tousey's statement is true; anode plate distance, 21 inches; tube shift, 3 inches.

will be found, however, that the line representing this relation is a parabola, which is quite easily constructed.

The true proposition is as follows: Let *TS* equal tube shift; *TR*, traverse of the foreign body; *AD*, anodal plate distance or distance from anode of the tube to the surface of the plate, and *X*, elevation of foreign body in space above plate. Then $Ts : Tr = AD - x : x$.

All that is necessary in order to prove the incorrectness of Dr. Tousey's statement is to assume that the foreign body in Tousey's case has a traverse on the plate of 1 inch. Then by his statement, with a distance of 21 inches and a tube shift of 3 inches this foreign body would lie 7⁄2 inches or 3½ inches in the tissues; whereas, if you solve the equation you will find that the foreign body must occupy a position 5¼ inches from the plate, making an error of 1¾ inches.

COMING EXAMINATIONS

Colorado: Denver, Jan. 8. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Delaware: Wilmington, Dec. 11-13. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

District of Columbia: Washington, Jan. 8. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

Florida: Jacksonville, Dec. 4-5. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Hawaii: Honolulu, Jan. 10-13. Sec., Dr. G. A. Batten, Box 375, Honolulu.

Indiana: Indianapolis, Jan. 8-10. Sec., Dr. Wm. T. Gott, 84 State House, Indianapolis.

Kentucky: Louisville, Dec. 4-6. Sec., Dr. A. T. McCormack, Bowling Green.

Louisiana: New Orleans, Dec. 6-8. Sec. Pro-tem., Dr. E. W. Mahler, 730 Audubon Bldg., New Orleans.

Maryland: Baltimore, Dec. 11. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

Minnesota: St. Paul, Jan. 2-4. Sec., Dr. Thomas McDavitt, 741 Lowry Bldg., St. Paul.

Missouri: St. Louis, Dec. 17-19. Sec., Dr. George H. Jones, 206 Washington St., Jefferson City.

National Board of Medical Examiners: New York City, Jan. 9-17. Sec., Dr. J. S. Rodman, 310 Real Estate Bldg., Broad and Chestnut Sts., Philadelphia.

New Hampshire: Concord, Dec. 10-12. Sec., Dr. W. T. Crosby, Beacon Bldg., Manchester.

New Mexico: Sante Fe, Jan. 14. Sec., Dr. R. K. McClanahan, East Las Vegas.

North Dakota: Grand Forks, Jan. 1. Sec., Dr. G. M. Williamson, Grand Forks.

Ohio: Columbus, Dec. 4-6. Sec. Pro-tem., Dr. Herbert M. Platter, 185 E. State St., Columbus.

Oklahoma: Oklahoma City, Jan. 8-9. Sec., Dr. J. J. Williams, Weatherford.

Oregon: Portland, Jan. 1. Sec., Dr. Herbert S. Nichols, Portland.

Pennsylvania: Philadelphia, Jan. 8-10. Sec., Nathan C. Schaeffer, State Capitol, Harrisburg.

Rhode Island: Providence, Jan. 3. Sec., Dr. B. U. Richards, State House, Providence.

South Dakota: Pierre, Jan. 8. Sec., Dr. P. B. Jenkins, Waubay.

Utah: Salt Lake City, Jan. 7-8. Cor. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.

Virginia: Richmond, Dec. 11-14. Sec., Dr. J. W. Preston, McBain Bldg., Roanoke.

Washington: Spokane, Jan. 1. Sec., Dr. C. N. Suttner, Baker Bldg., Walla Walla.

Wisconsin: Madison, Jan. 14. Sec., Dr. J. M. Dodd, 220 E. Second St., Ashland.

Texas June Examination

Dr. M. F. Bettencourt, secretary of the Texas State Board of Medical Examiners, reports the written examination held at Austin, June 19-21, 1917. The examination covered 12 subjects and included 120 questions. An average of 75 per cent. was required to pass. Of the 119 candidates examined, 115, including 9 osteopaths, passed and 4 failed. Forty-one candidates, including 2 osteopaths, were licensed through reciprocity, and 8 candidates were granted reregistration certificates. The following colleges were represented:

Book Notices

Obstetrics: A Text-Book for the Use of Students or Practitioners. By J. Whitridge Williams, Professor of Obstetrics, Johns Hopkins University. Fourth Edition. Cloth. Price, $7 net. Pp. 1029, with 708 illustrations. New York: D. Appleton & Co., 1917.

Five years have elapsed since the appearance of the last edition of this book. During that time, notable changes have taken place in the views held on some phases of obstetrics, even though no definite progress has been made. The author discusses this phase of the subject, and expresses opinions which, coming from a man of his standing, are not only worthy of consideration, but are significant and weight-bearing. Anesthesia in obstetrics has received much attention during the past five years. Williams endorses the use of nitrous oxid gas, but feels that it should be limited to the second stage. As for scopolamin-morphin anesthesia, he says the fact that we cannot promise a satisfactory subjective result to more than three patients out of four makes it apparent that the method is not ideal. He believes that it will gradually fall into disuse, or at least that its use will be restricted to a small group of neurotic patients. From his experience the method is not adapted to private practice. He is strongly opposed to lumbar anesthesia. His preference in normal labor is chloroform. The value of complicated chemical methods in determining the prognosis and treatment of preeclamptic toxemia and eclampsia is discounted by the author. He says that while the clinical differentiation between the nephritic and the preeclamptic types of toxemia is not always easy, fortunately the difficulty in diagnosis is of more importance from the scientific than from the practical point of view, as the treatment to be employed is identical in the two cases. While he regards the Abderhalden pregnancy reaction as one of the important recent contributions to medicine, he does not believe that it is destined to come into extensive practical use because, first, its technic is complicated; second, the results fail to correspond with the clinical findings in 5 or 10 per cent. of the cases, and third, it is valuable only in normal pregnancy. In speaking of pituitary extract, he says that his experience has shown that the judicious administration of the drug will do away with the necessity for the application of low forceps in from one third to one half of the cases in which this method was formerly employed; but he urges that great care should be exercised in the use of pituitary extract, as its injudicious employment may place the life of both mother and child in jeopardy. Furthermore, the claims made by several manufacturers concerning its harmlessness are inaccurate and extremely reprehensible, as they are calculated to lead inexperienced practitioners into therapeutic excess to the detriment of their patients. He believes that eventually the use of pituitary extract will be limited to the latter part of the second stage, and this only as a competitor with low forceps. The present revision will maintain the high standard of this work as a practical up-to-date guide to the obstetrician. Many new illustrations have been added. The bibliography given at the end of each chapter is valuable; it bears all the earmarks of having been verified.

Pain and Pleasure. By Henry Thomas Moore, Ph.D., Assistant Professor of Psychology, Dartmouth College. Cloth. Price, $1.25 net. Pp. 174, with 11 illustrations. New York: Moffat, Yard & Co., 1917.

The author states that pain may be described as of three fairly distinct types—surface pain, distinguished by sharp clearness, exactness of location and well coordinated reaction; bodily distress, characterized by obscure dulness, difficulty of exact location, and a general and somewhat aimless bodily reaction; and unpleasantness, marked by such obscurity that it is commonly spoken of as feeling. It has no particular location, but seems to pervade the whole body. Pleasure may be derived from stimulation of the surface of the body; gratification is the pleasure derived from satisfying the needs of the inner organs, a form of which is distinctly experienced for each of the body needs; then there is pleasantness, which is least capable of exact location or definition. Pain and pleasure as sensations have probably been evolved gradually out of a primitive obscure state of well-being, or pleasantness, and malaise, or unpleasantness. All three varieties of pain and pleasure described can be best accounted for by reference to the fact that every living organism is born with the capacity for struggle, and in an environment in which struggle is a fundamental law of nature. Pain signifies either that the environment has demanded too much of the organism's limited capacities, or that it has failed to offer a point of contact for unused activity. Pleasure signifies either that the environment has furnished occasion for a conflict to which the organism's powers are equal, or that opportunity is being afforded for recovery from a struggle carried to an extreme point—the pleasure of rest, for instance. As to the diagnostic value of pain, it is said that pain is the physician's most reliable dependence as a means of diagnosis, but it is necessary to have perpetually in mind the possibility that a given pain may be "imaginary" (psychasthenic or neurasthenic) or "referred" (giving a false indication as to the real source of the trouble). The former source of error can, in a measure, be guarded against by tests of suggestibility, by noting the change of facial expression, of blood pressure and of the pupil reflex. The author concludes what is an interesting psychologic study of pleasure and pain by saying, "Whether as sensation or as feeling, the broad significance of pain and pleasure is to be found in the fact that life is essentially a struggle, in which pleasure is the accompaniment of some form of mental or physical success, and pain is an indication of defeat or of abortive effort."

Health Survey of New Haven. A Report Presented to the Civic Federation of New Haven by Charles Edward Amory Winslow, James Cowan Greenway and David Greenburg of Yale University. Paper. Price, 75 cents. Pp. 114, with 30 illustrations. New Haven: Yale University Press, 1917.

This book deals with public health conditions in New Haven, and recommendations for their improvement. The report is unusually free from destructive criticism. Under each heading, conditions existing at the time of the investigation are given, followed by an analysis and specific recommendations for improvement. Forty-five such recommendations are made on the basis of the author's findings, following approved methods of public health administration but adapted to New Haven's needs. Such a report made by trained men should be of value to other cities as a guide in efficient organization and modern methods of public health administration. The authors have pointed out that New Haven is getting good service for the money expended, but that this amount needs to be increased from 30 cents per capita to 50 cents to secure the best results.

Psychological Tests. A Bibliography. Compiled by Helen Boardman, Research Worker for the Bureau of Educational Experiments. Paper. Price, 25 cents. Pp. 75. New York: Bureau of Educational Experiments, 1917.

While this is not an exhaustive bibliography, it is a very useful one; for the articles on this subject are numerous, and widely scattered through medical, psychologic and pedagogic journals. Each entry is followed by a brief annotation giving the scope of the article. The bibliography would present a much better appearance if the references were uniform in style. The volume number is given sometimes in Arabic and sometimes in Roman, and the date of the publication in some places precedes the volume and page and again follows it.

The Treatment of Emergencies. By Hubley R. Owen, M.D., Surgeon to the Philadelphia General Hospital. Cloth. Price, $2 net. Pp. 350, with 249 illustrations. Philadelphia: W. B. Saunders Company, 1917.

This book is essentially an enlargement of the author's lectures to policemen, firemen and nurses, and as such it is a commendable addition to first aid work, especially for all those, whether professional or lay, who wish to make a more comprehensive study of the subject. The author has aimed, in each instance, to give the underlying principle of each dressing and the reason for a particular method of application. The language used is plain and clearly descriptive, and no exception can be taken to the treatment of the subject or the correctness of the teachings.

Social Medicine, Medical Economics and Miscellany

Welfare of Mothers and Children in Ireland

The birth rate in Ireland has been diminishing for the past ten years; in 1915 there were 3,000 fewer births than in 1914, perhaps partly the result of conditions connected with the war. The deaths of children under 1 year for 1915 were 92 per thousand. In England during the same year the number was 110 per thousand, and in Scotland 126. While the figures for Ireland seem, therefore, to be better than those for England and Scotland, the comfort to be derived from them is diminished by the knowledge that in England and Scotland there has been a steady, rather rapid decline in the deaths under 1 year, whereas in Ireland the rate has remained almost stationary for many years.

These facts, together with many others regarding the welfare of mothers and children in Ireland, are set forth in the report of the Carnegie United Kingdom Trust on Ireland (1917) written by Dr. E. Coey Bigger, medical commissioner of the Local Government Board for Ireland. While the decline in the death rate in England among infants under 1 year has been 24 per cent., in Ireland it has not amounted to over 8 per cent., the actual figures for this age being for Ireland, 1891-1900, 104; 1901-1910, 96, and 1911-1915, 91, and for those from 1 to 4 years of age, 88.7, 58.9 and 52.5, respectively. The chief causes assigned are low wages and the low standard of living or downright poverty of a large proportion of the population; bad housing in city and country; increase in the urbanization of the population, with higher consequent death rate, and decline in breast nursing on account of the lowered vitality of mothers due to improper nourishment, the defective condition and deficiency of the milk supply, which is general throughout Ireland, the lack of knowledge of mothercraft, etc.

The greater death rate among infants of the laboring classes, the low wage earners, is marked and distinct, and its relation to the quantity and quality of the diet of the people is indicated in the following:

> For the past twenty years the available income of both laborers and farmers has risen, but the cost of food has, at the same time, risen and its nature has changed. Milk porridge and potatoes were once the staple food of the laboring and farming class; now it is bread and tea and potatoes—a change very much for the worse, and one which is bound to react on the infant by making the mother less fit to bear her child, and to suckle it when born.

The report shows that some progress is being made in improving the housing conditions, in better hospitalization, better reporting, better nursing and enlightenment with regard to artificial feeding, and in general welfare work by various organizations.

Report of New York Committee on Feeblemindedness

The New York Committee on Feeblemindedness, which was organized in March, 1916, under the chairmanship of R. Bayard Cutting, is carrying on a campaign in New York State to secure adequate provision for the care, supervision and training of the feebleminded and epileptic. The aims of the committee, as set forth in its first annual report, are to improve the usefulness of the state institutions for the benefit of the feebleminded, to further the establishment of special classes in the public schools, and to aid in the establishment of a system of guardianship and supervision in the home. Preventive measures, of course, are prominent in the committee's aims. To attain these objects, the committee is working along the following lines: the gathering and dissemination of information concerning the feebleminded; organization and leadership of individual effort and social agencies, and promotion of legislation.

A conservative estimate gives the number of feebleminded persons in New York State as 35,000, of whom 6,000 are provided for in proper institutions; 4,500 are detained in almshouses and jails without appropriate care, and over 24,000 are unprotected in the community, are the bearers of disease, and live in a state of poverty and degradation. It is shown that from 20 to 30 per cent. of the inmates of correctional institutions are mentally defective, and studies of habitual offenders show that nearly one half of all crime can be laid at the door of feeblemindedness. It has been estimated that 2 per cent. of the children in the public schools are retarded to such a degree as to constitute feeblemindedness. One of the great causes of feeblemindedness is heredity, and the birth rate among the mental defectives is found to be approximately twice that of the normal population. Prevention of marriage of feebleminded persons would reduce immediately the proportion of the feebleminded, paupers, criminals and no-account persons. It is said that the only means of accomplishing this which is agreeable to the sensibilities of the average citizen is segregation and institutional care. It is along these lines that the committee has been directing its efforts.

Medicolegal

Insufficient Information Under Statute Defining Practice of Medicine

(People vs. Watson (Mich.), 162 N. W. R. 943)

The Supreme Court of Michigan holds that the verdict should be set aside, and the defendant discharged in a case in which his conviction was under an information that alleged that he "unlawfully did engage in the business of practice of medicine, and did practice medicine, within the meaning of Act 237 of the Public Acts of the state of Michigan for the year 1899, and the amendments thereto, without before so doing having complied with the provisions of said act" and its amendments, etc. The court says that the information was bad because (1) the general words employed therein do not fully set forth all of the assignments necessary to constitute the offense; (2) the subject-matter of the offense is now defined by the statute by descriptive words, none of which are employed in the information; (3) a person may innocently do things embraced within the definition given in the statute.

Act 237, Public Acts of 1899, was amended by Act 368, Public Acts of 1913, so as to define the practice of medicine. Under former legislation it had been left to the courts to define—piecemeal, it is true, but nevertheless to define—what was the practice of medicine, by determining whether the proved acts of the person accused of violating the statute amounted to practicing medicine. The legislature undertook to make an exclusive and inclusive definition by enacting: "In this act, unless otherwise provided, the term 'practice of medicine' shall mean the actual diagnosing, curing or relieving in any degree, or professing or attempting to diagnose, treat, cure or relieve any human disease, ailment, defect or complaint, whether of physical or mental origin, by attendance or by advice, or by prescribing or furnishing any drug, medicine, appliance, manipulation or method, or by any therapeutic agent whatsoever." Here are the elements of the statute offense, a catalogue of the acts constituting "practice of medicine," the doing of which makes the actor liable to the statute penalty. Under such an act, to charge one generally with "practicing medicine" is not to charge him sufficiently with a wrongful act. Moreover, the foregoing statute definition is itself limited by the title of the act and the measure of the police power of the state. Some things within this statute category may be innocently done.

It will at once be perceived that the information before the court may or may not charge the defendant with committing an offense, in view of the definition of "practice of medicine" found in the act and the proper scope of the act, as evidenced and limited by its title; because, since the act has been sustained as valid on certain limitations of the definition, it is no longer sufficient to charge one with engaging in the business of practicing and with practicing medicine, contrary to the provision of the statute—the law having been held valid only when applied to such acts enumerated therein as "in common acceptation and as generally construed by the courts" are regarded as engaging in the "practice of medicine." The rule that in indictments and informations for offenses created by statute it is sufficient to describe the offense in the words of the statute, and that when the words of the statute are descriptive of the offense it is safe to follow the language there used, is a rule that was not observed by the pleader, since the descriptive words found in the present statute are not used in the information. Moreover, so long as a person may innocently do some things embraced within the definition given in this particular statute, there is additional reason for particularity of statement of the acts committed in order to apprise the accused of the charge sought to be brought against him.

Combining Faith with "Patent Medicines"

(People vs. Vogelgesang (N. Y.), 116 N. E. R. 977)

The Court of Appeals of New York, in affirming a judgment of conviction of the defendant of having illegally practiced medicine, says he claimed he was a spiritualist and had practiced the religious tenets of his church. If that was all he did, he acted within his rights. The court, however, thinks he did more. In February, 1915, one Haldeman, then suffering from heart disease, visited the defendant's office. He paid four visits there, and received three visits at his own home. He died the next month. The defendant rubbed his body with a liniment, and gave him medicine for internal use. All this was done for pay. The patient's wife accompanied him to the office. She said the defendant never uttered a word about spiritualism. The defendant handed to his patient a pamphlet, the title on the cover of which gave the defendant's name, and added the words: "Specialist in all forms of chronic diseases; strictly confidential; consultation free." Within the covers was a sketch of the defendant's life. It told that, when 11 years old, "he would get herbs and give them to sick people, for he seemed to know what would be good for them." In later years the Erie County Medical Society complained of him, and a fine was imposed. "After that," said the sketch, "he joined the New York State Association of Spiritualists." The sketch was followed by many testimonials from patients. All, or nearly all, acclaimed the virtue of his medicines. Not one of them betrayed a consciousness that the supposed cure had been wrought through the power of religion. This was the pamphlet by which the defendant accredited himself to Haldeman. One cannot find here the picture of the religious devotee. One can find only the picture of the unlicensed medical practitioner. The picture was not changed by the defendant's testimony. On the stand he characterized himself as a therapeutic and spiritualist healer and dealer in "patent medicines." He had patented them himself. He used a liniment, compounded of angleworms, turpentine, sweet oil and benzin. He said that, while massaging the patient with this liniment, he indulged in silent prayer. He also prescribed for internal use a medicine compounded of wine, beef tea and citrate of iron. The same medicine was used for every one. He argued that all this must be excused, because he had become a member of the spiritualist church, and had been commissioned by that church as a spiritual healer.

The New York statute prohibits the practice of medicine without a license, but excepts from its prohibition "the practice of the religious tenets of any church." This court held in *People* v. *Cole,* 219 N. Y. 98, 113 N. E. 790, that the exception protected the practitioners of Christian Science, who taught as part of their religion the healing power of mind. Even then the court said there were times when the question of their good faith must be submitted to a jury. But things were done by this defendant which no good faith could justify. He combined faith with "patent medicine." If he invoked the power of spirit, he did not forget to prescribe his drugs. "It is beyond all question or dispute," said Voltaire, "that magic words and ceremonies are quite capable of most effectually destroying a whole flock of sheep, if the words be accompanied by a sufficient quantity of arsenic." The law, in its protection of believers, has other cures in mind. The tenets to which it accords freedom, alike of practice and of profession, are not merely the tenets, but the religious tenets, of a church. The profession and the practice of the religion must be itself the cure. The sufferer's mind must be brought into submission to the infinite mind, and in this must be the healing. The operation of the power of spirit must be, not indirect and remote, but direct and immediate. If that were not so, a body of men who claimed divine inspiration might prescribe drugs and perform surgical operations under cover of the law. The law exacts no license for ministration by prayer or by the power of religion. But one who heals by other agencies must have the training of the expert.

Liability for Sponge and Silk Thread in Wound—Evidence

(Wynne et ux. vs. Harvey et al. (Wash.), 165 Pac. R. 67)

The Supreme Court of Washington says that in this action against the physicians and a nurse for alleged malpractice in connection with an operation on Mrs. Wynne for an enlarged uterus, after a trial of the case on the merits, a motion for nonsuit was granted as to the nurse, but a verdict for $5,000 was entered against the physicians. Now the action is ordered dismissed as to the assistant physician or surgeon, with costs to him, while the judgment is affirmed as to the physician or surgeon in chief.

The operation did not seem to be very successful, as the wound refused to heal and a fistula was formed, which discharged impure matter, including a silk thread. Afterward, through another operation, a small mop sponge was found, next to the inside of the abdominal wall. Defendant Harvey had been treating the plaintiff for some time prior to the first operation, but on account of the seriousness of the operation it was decided he should have an assistant, and the other physician was employed in that capacity, by Mr. Wynne. In cases of this character, the rule concerning the liability of two physicians independently engaged has been well stated to be that each, in serving with the other, is rightly held answerable for his own conduct, and as well for all the wrongful acts or omissions of the other, which in the exercise of reasonable diligence under the circumstances he should have observed. The evidence showed that this assistant had nothing to do with the sponges or mopping with them on the inside of the incision. It is obvious that he would not be liable for this negligence because of any wrongful act of his own. His activities were confined mainly to the outside of the wound, and, since the duties of an assistant are to do as directed by the chief operator, and there was no showing either that he was directed to keep track of the sponges or that it was made his duty by custom to do so, it is apparent that, in the exercise of reasonable diligence under the circumstances, no duty devolved on him to discover that the sponge was not removed, the omission of which would render him liable to an action for damages.

In considering the appeal of defendant Harvey, the court found that the complaint alleged negligence in the use of silk thread, instead of catgut, in tying off the arteries, and the only evidence to sustain this allegation was that a piece of silk thread was discharged through the fistula that formed in the plaintiff's body. Impliedly admitting that it was improper to use silk in tying off arteries, and to explain its presence, defendant Harvey claimed that it was used in suturing a ruptured intestine, and produced evidence to show that in so doing silk was the proper and better material to use. But while there was no direct evidence to show that silk was negligently used in tying off arteries, there was evidence to show that silk was negligently used, as the thread discharged through the fistula was No. 12, which, according to the testimony of the experts, was far too large for use in suturing a ruptured intestine, the majority of the experts being of the opinion that in no event should silk thread of larger size than No. 3 or No. 4 be used for this purpose. Precisely what use was made of the silk thread, and where, was manifestly unknown to the plaintiff, save by results. The exact place and manner were known to defendant Harvey, who used it, and he was chargeable with reasonable care, skill and knowledge in its use. The court does not consider this evidence a material variance from the allegations of the complaint, and there was, therefore, sufficient evidence to submit this issue to the jury's consideration.

There being no evidence in the record that the sponges were counted by the attending nurses, or that defendant Harvey knew there was another sponge in the incision, the facts in this case did not bring it within the asserted exception that it is not negligence for a surgeon to leave a foreign substance in a wound when in his professional judgment further exploration for such foreign substance would endanger the safety of the patient.

The plaintiff could testify to such commonplace conditions and effects as that dressings were sometimes changed by defendant Harvey and sometimes by a nurse; that sometimes he would not come when requested; that sometimes dressings were not changed and pus would dry on them, and that the drainage tubes were not sterilized every time the dressings were changed.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Annual meeting, held at Toledo, Ohio, Oct. 9-11, 1917

The President, Dr. Channing W. Barrett, Chicago, in the Chair

What Reliance Can Be Placed in Our Laboratory Findings in Central Nerve Syphilis?

Dr. Albert E. Sterne, Indianapolis: A positive Wassermann test of the blood, and especially of the spinal fluid, spells syphilis and syphilis only; but a negative serum Wassermann, and even a negative spinal fluid Wassermann, does not strictly indicate the absence of syphilis. Laboratory tests are merely clinical signs, which at times may be present or absent, like other symptoms; spinal fluid tests should always be made with blood serum tests, and their correct interpretation can be made only by weighing carefully the clinical evidence, with the serologic report, especially when the latter are negative. The laboratory findings should fit into the clinical syndrome, and not vice versa.

Intensive Combined Treatment of Syphilis

Dr. J. H. Stokes, Rochester, Minn.: We have come to regard the effect of mercury on the kidney as the weak point in radical methods in the management of syphilis. This applies with special force to the intramuscular injection, and especially to the injection of insoluble mercurial salt, the convenience of which may easily be counterbalanced by much damage that goes undetected because of the irksomeness, to the majority of physicians, of the frequent, careful urinalysis. Radical treatment is indispensable; therefore, means to protect the kidney, especially, from its very real dangers should be devised.

Some Recent Developments in Intraspinal Therapy

Dr. Oscar Berghausen, St. Louis: In the treatment of epidemic meningitis, no one who has followed the results carefully will dispute the advantages to be gained by the withdrawal of the spinal fluid and subsequent introduction of the specific serum in these patients. The mortality is now, roughly speaking, about 50 per cent. in public institutions, whereas formerly it was 75 per cent. The combined intravenous and intraspinal injection of antitetanic serum has the advantage of sending the serum to all parts of the body. The former enormous doses are not necessary. Much smaller amounts will suffice, if the serum is used both intraspinally and intravenously. In the treatment of syphilis of the central nervous system, simple drainage of the subarachnoid space, or drainage plus the introduction of a normal serum, or a serum to which minimal amounts of salvarsan have been added, not to exceed from 0.1 to 0.5 mg., is a safe and sound procedure.

DISCUSSION

Dr. Hugh T. Patrick, Chicago: It is important that our serologic examinations should be made by men who are laboratory experts. We should not consider any evidence, however negative it may be, as evidence of cure. Any patient with syphilis who has been cured temporarily and has apparently become entirely well should be subjected to reexamination, not the ordinary clinical examination, but examination of the blood and also of the spinal fluid every six months for a considerable time.

Dr. R. B. H. Gradwohl, St. Louis: The whole question of the Wassermann reaction in the treatment of syphilis is a complicated one. While it is a very useful test as a diagnostic measure, as a prognostic measure, as a guide for treatment, we cannot always make deductions mathematically from it.

Dr. F. B. Wynn, Indianapolis: The inunction treatment is the most effective form of mercurial treatment, although the injection treatment is the most popular.

Goiter from the Standpoint of the Pathologist

Dr. Louis B. Wilson, Rochester, Minn.: Most of the malignant tumors of the thyroid have their origin in nodular adenomas which are usually passed over as benign. When we consider that the metastases from such cases are frequently in the lungs, and that both from the clinical and the gross anatomic standpoint they are difficult to distinguish from miliary tuberculosis of the lungs, I am convinced that many of them are diagnosed as the latter affection when in reality they are due to malignant neoplasms primary in the thyroid. Unless a necropsy is performed in such cases, the clinical diagnosis is of little value.

Goiter from the Standpoint of the General Practitioner

Dr. Granville N. Ryan, Des Moines, Iowa: One must keept in mind constantly the individuality and personal equation of each patient. A complete and painstaking history is most essential. The parenchymatous varieties that occur in the young are the most amenable to medical treatment, if not of too long standing. If degeneration has occurred in a case of long standing, the case is a medical one until the damage is repaired and the patient is surgically fit. In hyperthyroidism, the end result desired can be attained only by team work.

Goiter from the Standpoint of the Laryngologist

Dr. Joseph C. Beck, Chicago: The thyroid, so far as the laryngologist is concerned, is considered only when it produces pressure, causing either paresis or paralysis of the muscles supplied by the recurrent laryngeal nerve, or tracheal compression. Another aspect to be considered in cases of chronic infection of the upper respiratory tract producing a thyroid gland change is that of the toxemias acting on the autonomic nervous system, which changes the harmonic action of the various glands of internal secretion so as to produce thyroid disease. The advanced laryngologist, the laryngologist who has had a thorough training in general surgical principles, should encroach on this phase of surgery, especially when there are symptoms referable to the larynx and trachea.

The Heart in Goiter

Dr. Robert H. Babcock, Chicago: The treatment of mechanical derangements is surgical. In the toxic form, the treatment must also be directed to the thyroid rather than to the heart, except in certain cases in which treatment of the heart condition is understood. Our usual medicaments, such as digitalis, exert very little effect on the goiter heart, sometimes actually increasing the discomfort from palpitation. Rest, mental and physical rest, in proper environment, and careful diet are, perhaps, the best measures to allay the unpleasant sensation of palpitation. I have found that in some cases tincture of aconite, in doses of from 20 to 30 minims, three or four times a day, considerably lessens the patient's sense of discomfort. On the whole, however, except so far as we may obtain some relief from the use of serum or preparations from thyroidectomized goats, the treatment is surgical.

Surgery of Exophthalmic Goiter

Dr. Harry G. Sloan, Cleveland: Once the diagnosis of exophthalmic goiter is made, we advise operation. We put the patients to bed so that they may have absolute physical rest; we overfeed them, keep them in the fresh air as much as possible, and see that proper elimination from bowels and kidneys is obtained. The patient is given 10 grains of thyroid extract the evening before operation, and after operation 5 grains, every two hours, for the first day and a half. The body tissues have been depending on the secretion of the thyroid for some substance that aids in the oxidation of the waste product, and the sudden removal of the thyroid handicaps the organism until compensation takes place. Hence the substitution of thyroid extract. The immediate after-results vary with the severity of the disease and the length of time it has existed. All patients who recover after thyroidectomy are improved or permanently cured.

Nonsyphilitic Aortitis

Dr. Willard C. Stoner, Cleveland: It is accepted that acute infections, such as influenza and pneumonia, play no small part in producing aortitis. The intoxicants, such as alcohol, lead and tobacco, play some part, but no doubt alcohol is overestimated as a cause. Overeating as a cause of vascular hypertension and vascular disease cannot be overestimated. Anything that tends to overactivity of the suprarenals tends to vascular disease. Chronic foci of infection, such as bad teeth or tonsils, may be responsible for arterial change. Rheumatic fever may cause aortitis in association with valvular disease, and aortic changes are reported frequently as a result of typhoid. The question arises, What can be done for these patients? We cannot give them new aortas, but we can give them comfort. Absolute rest in bed for a period of time has a distinct value in the lowering of tension. All worry and strenuousness in life should be avoided. Encouragement of elimination and low protein diet should be advised, and if the patient is obese, weight should be reduced. Medicinally, iodids and nitrites are indicated. If the process is acute, direct therapy should be instituted for the general condition, bearing in mind that these patients are to be managed rather than treated.

The Value of the Complement Fixation Test in the Diagnosis of Incipient Tuberculosis

Dr. R. B. H. Gradwohl, St. Louis: The complement fixation test is absolutely specific for tuberculosis. It is not always present in all cases, and it seems to disappear when the process subsides. This test will be found a valuable addition to the diagnostic aids of the clinician. We have very few data on which to base a conclusion that negative reactions mean arrest of tuberculous processes. The observation of the patient over long periods of time must still remain the proper method of adjudicating this question.

Cancer Research in Switzerland.—The Swiss Cancer Research Association is appealing to the physicians of Switzerland to fill out a question blank which is being distributed to obtain data on mammary cancer. The appeal states that Switzerland is one of the countries where cancer is most prevalent, and cancer of the breast in particular seems to be on the increase. Physicians are asked to supply the data in regard to all the cases of mammary cancer encountered in the five years ending with 1915, cured or still under treatment at this date. For each response a fee of 40 cents is paid. Each physician who made out a death certificate during those years in a case of mammary cancer will be sent a question blank. The points to be specially noted are the influence of lactation, of preceding inflammatory affections or benign tumors, the influence of operative treatment on the prognosis in general and on metastasis in particular, and the actual value of roentgen and radioactive treatment.

9. **Syphilis of Pulmonary Artery.**—Up to the present no positive pathologic evidence of the existence of a syphilitic atherosclerosis of the pulmonary artery has been produced. Warthin's case offers such positive evidence; and syphilis of the pulmonary artery is now put on the same basis as that of the aorta. The microscopic changes in the atherosclerotic pulmonary artery of this case show exactly similar changes to those found in the wall of definitely recognized syphilitic aortas. Given sections of this pulmonary vessel cannot be distinguished microscopically from given sections of syphilitic aortas. The evidence here speaks decidedly in favor of the view of the specific nature of this especial form of arterial change. From Warthin's experience he believes that atherosclerosis, either of the ordinary type or of the syphilitic type macroscopically, that shows on microscopic examination perivascular infiltrations of lymphocytes and plasma cells along the course of the vasa vasorum, most marked in the adventitia; and following the vessels in their course through the media toward the intima, with obliteration of the arterioles, new formation of capillaries, fibroblastic proliferation, fibrosis of intima and media, secondary hyaline change and atheroma, is specific in character, and is due to the localization of the *Spirochaeta pallida* along the vasa vasorum.

Macroscopically the picture presented by the affected artery may be that of ordinary atherosclerosis or of the type recognized at the present time as syphilitic mesaortitis. Syphilis cannot be ruled out by the naked eye appearances of the aorta or artery at the necropsy table; the necropsy diagnosis of syphilis, however, can be made on the macroscopic criteria of syphilitic mesaortitis, as given above. Aortas presenting the gross picture of atherosclerosis may show on microscopic examination the most marked syphilitic infiltrations of the media and adventitia, and in Levaditi blocks from the same the presence of spirochetes has been shown. The microscopic examination is the only method by which syphilis of a vessel can be determined; macroscopic appearances cannot be relied on. The gross appearances of the pulmonary artery in this case were those of atherosclerosis. Had it not been for the aneurysm present its syphilitic nature would not have been sought and demonstrated.

10. **Latent Syphilis in Canal Zone.**—From a total of 1,198 colored surgical patients seen by Qualls, 908 showed no evidence of syphilis or gave history suggestive of the disease; 297 showed active evidence of syphilis or gave histories indicating previous syphilitic infection. The Wassermann test survey shows 23.7 per cent. of the nonsuspects to be syphilitic, and 36.7 per cent. of the suspects to be syphilitic. A grand total syphilitic infection of 27 per cent. exists among all colored employees admitted to the surgical wards. The latent syphilitic infection among colored male employees in the Canal Zone is exceedingly high; 23.7 per cent., as compared with the white employees showing 2.3 per cent. The total syphilitic infection among the white surgical patients is 15 per cent.

14. **Causes of Arterial Hypertension.**—Of 678 patients seen by McLester 124 had arterial hypertension varying from 155 mm. to 200 mm. and over. The average age of these patients was 53.75 years. Thirty-three patients gave a history of typhoid, 14 of pneumonia, 3 of yellow fever and 3 of recent scarlet fever. Only 6 patients admitted the excessive use of alcohol. The heart was enlarged in 67 instances, about 50 per cent. Albumin alone was found in the urine in 29 instances, and both albumin and casts in 61, or 50 per cent. of the cases. It is unfortunate that the phenolsulphonephthalein test of kidney function was made in only 11 of these, the average excretion in two hours being 49 per cent. The urine of 10 patients, 8 per cent. of the whole group, contained sugar. Among the focal infections were noted: 4 instances of diseased tonsils, 4 of infection of the accessory nasal cavities, 42 of diseased teeth (35 per cent.), 4 of chronic appendicitis, and 5 each of gallbladder and urinary tract infections. Twenty-one patients, or 17.5 per cent., gave a positive Wassermann reaction. Of the entire series of 678 patients 16.5 per cent. gave a positive Wassermann reaction.

17. **Roentgen Diagnosis of Lung Syphilis.**—Observations made by Watkins on approximately 1,000 chest roentgenograms justify the assertion that not fewer than 15 per cent. of tuberculous patients have also a syphilitic infection.

19. **Wassermann Reaction in Four Hundred Cases.**—The 400 cases studied by Knapp showed that men are five times more frequently syphilitic than women; that the central nervous system leaves demonstrable traces of the disease in 50 per cent. of the cases; that most of the cerebrospinal syphilis cases are in the male division; that the most important single method of examination for syphilis is the physical examination, the Wassermann second and the history least. The most convincing clinical diagnosis is when physical examination, Wassermann and history are all positive, the next in importance where two are positive and one negative, and the least where but one gives positive evidence.

31. **Relation of Spinal Cord to Spontaneous Liberation of Epinephrin.**—After section of the spinal cord in cats in the cervical region, as low as the last cervical segment, epinephrin continues to be liberated from the suprarenal glands. This liberation has all the characters of the normal secretion with intact central nervous system. It is sustained through the same nerve paths connecting the cord with the suprarenals. After section of the cord in the middorsal region the spontaneous liberation of epinephrin from the suprarenals is abolished within the limits of detectability by the methods employed (denervated eye reactions of Meltzer, and rabbit intestine and uterus segments). The portion of the cord concerned in the liberation of epinephrin does not appear to extend much below the third thoracic segment. In acute experiments on cats under urethan anesthesia no change in the rate of liberation of epinephrin which could be detected by the tests employed, was observed when the cord was severed in the cervical region.

32. **Effect of Stimulation on Rate of Liberation of Epinephrin.**—An attempt was made to determine whether stimulation of afferent nerves (sciatic and brachial) produced a detectable increase in the rate of liberation of epinephrin from the suprarenals, as determined by testing suprarenal vein blood on rabbit intestine and uterus segments. The result was negative.

35. **Toxicity of Intestinal Secretion.**—Davis and Stone assert that intestinal secretion collected by the method described in this paper is nontoxic when fresh. This secretion, when heated immediately to 90 to 95 C. and kept sterile, remains nontoxic. This secretion when not heated remains nontoxic when kept under chloroform and toluene, even if incubated at 37 C. This secretion when not heated, but collected in a sterile flask, becomes toxic on incubating eighteen hours, producing symptoms like those of closed loop fluid. The secretion, when treated with chloroform and toluene, and later incubated for eighteen hours, after these preservatives have been removed by distillation at 60 C., does not produce lesions typical of closed loop fluid.

38. **Attempt to Produce Glomerulonephritis by Injections of Bacteria.**—Repeated injections into the blood stream of streptococci and staphylococci derived from cases of scarlet fever, and of *Bacillus coli-communior* failed to produce typical glomerulonephritis even when immune bodies could be demonstrated in the serum in high dilutions. Bacteriolysis of streptococci was not found by the usual tests in vitro or by the Pfeiffer procedure.

39. **Heart and Pancreas in Sugar Metabolism.**—When the pancreas of a dog is perfused aseptically with a Locke's solution containing dextrose in physiologic concentrations, the optical rotation of the perfusate is diminished, but its reducing power is unaltered. This change also occurs if dextrose is added to a sugar-free pancreatic perfusate and the mixture incubated. These perfusates yield osazones with lower melting points than glucosazone, but when the per-

fusates are hydrolyzed with weak acid their optical rotations and the melting points of their osazones are increased. These changes do not occur with levulose, or with an extract of the pancreas and dextrose. When the heart, spleen or kidneys are perfused with dextrose solutions, hydrolysis of the perfusates does not increase their optical rotation or power of reduction. When a pancreatic perfusate containing dextrose is circulated through a living heart, not only do the above changes take place but, in addition, the reducing properties of the perfusate are altered. Hydrolysis of such a perfusate increases its reducing power, its optical rotation, and the melting point of its osazone. A heart does not cause this effect either alone or when perfused together with the spleen or kidneys. Levulose perfused through the heart and pancreas is unchanged. These phenomena are believed to be due to an enzyme or enzymes obtained from the perfused pancreas. The changes in optical rotation, in reduction, and in the osazones are accounted for by different degrees of dextrose condensation. While the living heart can destroy both dextrose and levulose to some extent, the experimental results suggest that the enzyme or enzymes derived from the perfused pancreas have a specific action on dextrose and are responsible for certain essential steps by which dextrose is prepared for normal utilization.

40. **Carriage of Virus of Poliomyelitis.**—A family group containing four children of whom all showed in varying degree symptoms of poliomyelitis is described by Taylor and Amoss. The source of infection and periods of incubation have been followed. Two of the children were proved by inoculation tests to carry the virus of poliomyelitis in the nasopharynx. Of these, one was detected to be a carrier after recovering from a nonparalytic attack of the disease, and the other was discovered to be a carrier about five days before the initial symptoms, attended later by paralysis, appeared. The original case from which the three others took origin was fatal; the youngest child, after quite a severe onset, was treated with immune serum and made a prompt and almost perfect recovery. The nasopharyngeal secretions of two of the patients, taken one month after the attack, proved incapable of neutralizing an active poliomyelitis virus. The proposition is presented that every case of poliomyelitis develops from a carrier of the microbic cause, or virus, of poliomyelitis.

Journal of Immunology, Baltimore

41 *Anaphylaxis in Dogs. The Liver in Shock and in Peptone Poisoning.—R. Weil, New York.—p. 525.
42 Tissue Transplantation and Anaphylaxis. L. Loeb, Washington, D. C.—p. 557.
43 Anaphylactic Reactions of Isolated Dog's Liver. R. Weil and C. Eggleston, New York.—p. 571.
44 New Method for Making Wassermann Antigens from Normal Heart Tissue. C. A. Neymann and L. T. Gager, Baltimore.—p. 573.

41. **Liver in Shock and Peptone Poisoning.**—Weil found that blood taken from dogs at the height of anaphylactic shock fails to produce any symptoms when injected, even in very large amounts, into normal animals, indicating that the blood does not contain any toxic substance. The isolated liver of a sensitized dog does not alter the coagulability of blood with which it is perfused; if, however, the antigenic substance is added to the blood before it traverses the organ, it passes out with its coagulability either diminished or completely abolished. The normal liver exercises no such effect. The injection of the antigenic substance, even in very small amount, into one branch of the portal vein of a sensitized dog produces an immediate severe congestion of the corresponding lobe of the liver. The blood rapidly becomes incoagulable, and symptoms of shock develop. Subsurface injection of the antigen into the sensitized liver produces a local focus of congestion. The postmortem examination of dogs dying in acute anaphylactic shock, within one hour, reveals as the single outstanding feature the enormous congestion of the liver. The other abdominal viscera show either very little congestion or none. The marked congestion of the gastro-intestinal tract in dogs dying after an interval of several hours is a late phenomenon, probably secondary to the congestion of the liver. Microscopic examination shows intense congestion of the liver, and degenerative changes in the parenchyma cells. Peptone affects the liver in exactly the same fashion as does anaphylaxis. The isolated organ, when perfused thereby, renders the blood incoagulable. Injection into one branch of the portal vein induces a localized area of hepatic congestion. The peptone theory of hepatic shock maintains that peptones are produced during the anaphylactic reaction, and that they are directly responsible for the symptoms. There are no experimental observations which establish this theory. It is based chiefly on the resemblances between peptone intoxication and anaphylactic shock, and these are adequately explained by the fact that in both conditions the same hepatic mechanism is affected. The peptone theory cannot be harmonized with the experimental data recorded in this paper. These results introduce a new function of the liver, namely, its participation in the immune reaction.

45. **Antityphoid Vaccination and Agglutination Test.**—The total number of quantitative tests performed by Rist from February to November, 1915, amounted to 11,648. He found that in nonvaccinated individuals the agglutination test is of the greatest practical value for diagnosing infection caused by the bacilli of the typhoid group. But, when it comes to discriminate between the three subspecies belonging to that group, the information given by the Widal test should be accepted with great caution. A predominance of the agglutination titer of *B. paratyphoid* A or B speaks almost certainly in favor of *B. paratyphoid* A or B. But if the agglutination titer of *B. typhosus* predominates, the probability of the disease being due to *B. typhosus* is only 73.3 per 100. In individuals having been previously vaccinated against *B. typhosus*, the agglutination test is absolutely unable to confirm a clinical diagnosis of typhoid. The behavior of the agglutination titer in vaccinated typhoid or paratyphoid patients is not distinguishable from the behavior of the same titer in vaccinated individuals suffering from any other disease. In a case of clinically confirmed typhoid occurring in a previously vaccinated individual, the agglutination test has a practical diagnostic value whenever it shows a constant predominance of the agglutination titer for one of the paratyphoid germs. But this is a very rare finding. In the greater majority of cases the agglutinating titer for *B. typhosus* predominates. It has no diagnostic value, the probability of mistaking paratyphoid for typhoid being slight. Blood culture is therefore the only reliable method to ascertain whether a typhoid infection occurring in a vaccinated person is due to *B. typhosus* or to one of the paratyphoid germs.

46. ***Antibodies in Gonococcal Arthritis After Protein Injection.***—It is shown by Culver that primary and secondary proteose preparations stimulate antibody production or mobilization for specific organisms in gonococcal arthritis in a

manner not to be distinguished from that produced by the injection of the specific organisms themselves. In gonococcal arthritis there is either no change or a decrease in the antibody content of serum within the first twenty-four hours following an intravenous injection in all excepting the first injection when the lytic substances seem to be slightly increased during this time. In favorable patients the first injection usually causes the greatest clinical benefit. However, refractory patients may give a similar lysin increase during the first twenty-four hours following an injection; hence the subjective and objective improvement in favorable cases cannot unquestionably be attributed to an increase in antibodies alone.

47. **Blood and Urine Ammonia in Acidosis.**—During the course of routine analyses for urea of the blood of a chronic alcoholic, who was suffering from repeated periodic attacks of nausea and vomiting of unknown etiology, an estimation of his blood ammonia was made, and it showed an ammonia content of 23 mg. of ammonia per hundred cubic centimeters blood. Similar analyses were made in cases of nephritis, cardiac failure, chronic diseases of the liver, toxemias of pregnancy and acidosis. Increases of blood ammonia of above 1 mg. per hundred cubic centimeters are ocasionally encountered in various diseases. Such increases cannot be explained by acidosis in all cases. The fact that nine cases showing marked increases (over 3 mg. per hundred cubic centimeters), which have come to necropsy, have shown definite hepatic lesions would suggest some connection between increased blood ammonia and functional insufficiency of the liver. The fact that of ten chronic and subacute cases of inflammatory disease of the liver studied only one has shown an increase of blood ammonia would indicate acute functional insufficiency of the liver cells rather than acute or chronic inflammatory changes in the liver parenchyma as the source of any blood ammonia increase.

48. **Infectious Meningitis.**—The most important lesson to be drawn from this study concerns lumbar puncture and spinal fluid. Correct antemortem diagnoses were established in 100 per cent. of cases in which proper lumbar punctures and spinal fluid examinations were made. Correct antemortem diagnoses were not established in 70 per cent. of cases in which proper lumbar punctures and spinal fluid examinations were neglected. Graves advises that in drawing spinal fluid the second portion should always be collected in a separate, clean, dry, sterilized test tube. Any blood in the specimen to be examined renders findings unreliable, wastes time and material and may lead to incorrect conclusions.

49. **Prevention of Simple Goiter.**—In a complete census taken by Marine and Kimball of the condition of the thyroid in the girls from the fifth to twelfth grades of the school population of a large community in the Great Lakes goiter district, it was found that 1,688, or 43.59 per cent., had normal thyroids; 2,184, or 56.41 per cent., had enlarged thyroids; and 594, or 13.4 per cent., had well defined, persistent thyroglossal stalks. The community lies near the southern edge of the goiter district and it is suggested that communities near the lakes would show a higher incidence. The following method of prophylaxis proposed is in operation. For the prophylactic treatment the authors have selected sodium iodid on the grounds of economy and ease of administration. One mg. of iodin given weekly, by mouth, is ample to prevent goiter in dogs. In all their dispensary experiments with children the authors used either syrup of hydriodic acid or syrup of ferrous iodid, in 1 c.c. doses, daily for two to three weeks, repeated twice yearly. They have, therefore, arbitrarily selected to use 2 gm. sodium iodid, given in 0.2 gm. doses each school day, for each pupil in fifth, sixth, seventh and eighth grades; and 4 gm. given in 0.4 gm. doses each school day for each pupil in the ninth, tenth, eleventh and twelfth grades. These amounts will be given twice annually about the first of May and December, at the schools by the teachers or nurses. These amounts of sodium iodid provide approximately 1,700 (1,692) mg. of iodin for each pupil of the fifth, sixth, seventh and eighth grades and approximately 3,400 (3,384) mg. for the ninth, tenth, eleventh and twelfth grades.

50. **Transplantation of Thymus.**—The preliminary experiments reported on by Marine and Manley show that in sexually immature rabbits, fragments of thymus autotransplanted into the subcutaneous tissue of the abdomen after thymectomy may "take," grow and survive. There is clear though scant evidence in confirmation of other observers' results, that thymus removal hastens sexual maturity. Also, as others have found, utilization of rabbits for breeding hastens involution of the thymus. The authors' experiments show that this applies to the transplanted thymus as well, and this suggests that a specific nerve influence is not essential for these involutionary changes.

51. **Besredka's Antigen in Tuberculosis Complement Fixation Test.**—As for the percentage of the occurrence of the reaction in different stages of tuberculosis when a purified antigen of Besredka is used, Bronfenbrenner presents these approximate figures: first stage, 84 per cent.; second stage, 94 per cent.; third stage, 15.3 per cent.; clinically nontuberculous (controls), nonsyphilitics, 5 per cent. The question of surprisingly low percentage of positive results in far advanced cases was especially investigated. In addition to the Besredka antigen, Bronfenbrenner examined a large group of such cases (from Leech Farm, Pittsburgh), with the antigens of Craig, Corper and Calmette, and more recently also with antigen of Miller. Although it was possible to observe a slight variation in the results obtained with respective antigens, in general they reacted no better than that of Besredka.

54. **Wassermann Test with Large Amounts of Serum.**—The use of a large amount of serum does not, in van Saun's experiences, change a serum giving a negative reaction to one giving a positive if a double serum control (0.8 c.c.) is used and the result of the test read only when this control is completely hemolyzed. In a number of tests she has found that the 0.4 c.c. control has been extremely slow to hemolyze, and has occasionally fixed complement completely. This result appears to point to a lack of specificity in a test depending on this amount of diagnosis. Van Saun does not consider the Kromayer modification a safe method to use for the practical examination of large numbers of serums.

56. **Simple Method of Obtaining Blood Serum.**—Wohl describes his method as follows: Place a small piece of paraffin (0.5 gm. is sufficient for an ordinary 6 inch serologic test tube) into a container that is ready for sterilization, cork it and sterilize it. On removal of container from sterilizer roll it so as to cover its walls with the paraffin. It takes only a few minutes until the thin film of paraffin is hardened. To clean the container, rinse it with cold water until all the blood is removed, melt the paraffin and pour off. The excess of paraffin is removed by means of a gauze applicator.

73. **Degeneration of Peripheral Nerves.**—The object of Manalang's work is to determine the presence of degeneration in the peripheral nerves of diseases other than beriberi and to emphasize the presence of the degeneration in nonberiberics. In a mixed necropsy service in Manila 88 out of 104 cases showed microscopically degeneration of the peripheral nerves by the Marchi method. Of these 88 cases the degeneration was slight in 55, moderate in 29, and marked in 4. Of the 88 cases of nerve degeneration more than half (49) occurred between the ages of 20 and 50 years, but no age was exempt. Of the 88 cases of nerve degeneration there was nephritis of some form in 69. Manalang found that the condition of nutrition is not an important factor in determining the nerve degeneration, and a reasonable interval (two to forty-eight hours) between death and necropsy does not necessarily mean a sequential myelin sheath change, as demonstrated by the Marchi method. (These bodies were kept at a temperature just above freezing.) With the knowledge that this study was made from a routine necropsy service in Manila and that the subjects were all Filipinos, the following factors must be taken into consideration in attempting to explain the occurrence of degeneration in 88 out of 104 cases studied. In Manila beriberi is endemic, and therefore there is the possibility of many persons with unrecognized mild beriberi dying of other diseases. There may be many patients who recovered from beriberi and died of other diseases. The nutrition of the working class of Filipinos in general is below par, due to insufficient food, excessive nonnutritious food, or a one-sided diet.

75. **Treatment of Pregnant Cholera Patients.**—The essential factor in the treatment of pregnant cholera patients according to Lowell is to remove the dead fetus as soon as possible and in the manner best suited to the mother's condition, because it shortens the period of convalescence, preserves the strength of the mother, and reduces the mortality to about that of the nonpregnant cases.

84. **Exstrophy of Bladder.**—Haggard's patient made an uninterrupted recovery, passing a normal quantity of urine through the catheters, which protruded from the rectum and which were left in place for four days. After that time the patient passed the urine through the rectum at frequent intervals, which have gradually lengthened, until now at the end of three years she is able to retain the urine from three to four hours by day and from five to six hours at night. There has never been any leakage whatever. The anterior wound healed over completely. Her general health is unimpaired.

5. **New Herniotomy.**—The operation described by Hull aims to remove the sac at the heighest possible level with the minimum disturbance of tissue. No dissection of tissues is undertaken, or injuring the delicate or important structures which surround a hernial sac by attacking the hernia from within the sac. Under local anesthesia an incision from half an inch to an inch in length is made and carried down to the aponeurosis of the external oblique. The fibers of the external oblique are split for a distance of half an inch. The opening in the external oblique should lie directly over the spermatic cord. The cremasteric and spermatic fascial coverings of the cord are drawn through the aperture of the external oblique. The cremasteric fibers are separated and the spermatic fascia incised. Two pairs of fine hemostatic forceps are placed on the edge of the sac, and an incision half an inch in extent, made between them by a snip of a pair of scissors. The two layers of the sac forming the lips of the aperture are now clipped with hemostatic forceps. The aperture can now be held open by four pairs of forceps, and four incisions are made, one between each pair of forceps, enlarging the aperture sufficiently to display the interior. If omentum lies in the sac it is drawn out, ligatured, and cut off. This interior of the sac presents for examination two apertures, one the internal ring passing into the abdomen, the other passing down the inguinal canal. These apertures are separated from one another by a process of peritoneum, the crista which corresponds to the internal margin of the internal ring. The neck of the sac is exposed and freed without

dissecton. A gauze swab is gently passed down the outer and inner side of the sac. A gentle pull is made on the neck of the sac while it is ligatured as high up as possible. It is unnecessary and undesirable to perform any displacing maneuver to the neck of the sac. When the sac is cut off distal to the ligature, the elasticity of the peritoneum will displace the ligatured sac well behind the rectus muscle. In 90 per cent. of cases this is all that it is necessary to do, and the skin incision is sutured with silkworm gut passing down to, and taking up the edge of the external oblique.

16. **Trench Feet Treated by Passive Hyperemia.**—Turner's experience with this form of treatment has been satisfactory to him. In slight and moderate cases the swelling of the foot has usually disappeared in twenty-four or forty-eight hours after the application of the bandage. In severe cases it may persist longer. Pain improves rapidly, and in twenty-four hours has either disappeared or has markedly diminished. Anesthesia improves steadily, but not so rapidly. In a moderate case with anesthesia of all the toes and of the greater part of the dorsum of the foot the sensation will probably be normal in four days, with the exception of blisters and gangrenous spots where the sensation is naturally still deficient. In cases of moderate severity blisters and the gangrenous areas shrivel, dry up, and eventually separate, leaving an unbroken delicate pink skin underneath. Not infrequently there is an extensive desquamation of the skin of the affected part, sometimes of practically the whole foot. In extensive cases, after the separation of dried blisters, gangrenous spots, and epithelial scales, there is left a surface of thin, pink, soft skin resembling a baby's foot. This is naturally very tender, and though the patient can walk in soft shoes, boots cannot be worn until the thin skin has become hardened and accustomed to pressure. Turner regards this desquamation and separation of dried gangrenous areas as part of the natural process of cure in these cases of moderate severity, and thinks that the treatment by passive hyperemia considerably accelerates the process. In slight cases, as soon as pain, swelling and anesthesia have disappeared, usually after four or five days, the patient is allowed to walk in soft shoes. Then after two days boots are worn at first for half an hour daily. This period is gradually increased until the boots can be worn for two hours without discomfort, when the man is discharged to the convalescent depôt. In moderate cases the procedure is the same. A longer period is, however, required before walking is possible and before boots can be worn. Severe cases always require evacuation to England.

17. **War Wounds Treated with Flavine.**—This is the authors' report to the medical research committee. Flavine was tested out by Drummond and McNee clinically as well as in the laboratory. Seventy patients, many having multiple injuries, were treated. The flavine was at first employed in a strength of 1 in 1,000, the dilution being made in normal saline solution, in which the powder is readily soluble. This routine was soon given up, however, as it was found that equally good results ensued if the use of 1 in 1,000 solution for the first dressing was followed by the employment of a solution 1 in 5,000 for all subsequent applications. In some cases, also, where the Carrel method of irrigation was being used, the strength of the solution was further reduced to 1 in 10,000. The surgical methods adopted depended on the type of injury met with. Long incisions, with free excision of damaged muscle and fascia, must be regarded as a cardinal part of all operative treatment in recent wounds, no matter what subsequent methods are employed. After this preliminary surgical treatment the wounds treated with flavine were dealt with in the following ways: 1. Primary suture. 2. Drainage by tube or gauze strip, followed by secondary suture. 3. The Carrel method of intermittent irrigation. 4. Gauze packing in open wounds. Wounds treated by excision of the infected and damaged tissue, followed by primary suture, gave excellent results.

Secondary suture gave good results in all the cases in which it was adopted. In open wounds on removal of the first dressing on the third day the wound, except for being deeply stained with flavine, has undergone no alteration whatever in its appearance, and resembles an injury only a few hours old. All signs of inflammation are wanting, and there is no pain, redness, swelling, or induration in the tissues around. The secretion from the wound is minimal in amount and suppuraton is absent. The complete absence of suppuration, even in wounds where films show abundant organisms to be present, is a noteworthy feature in wounds under treatment with flavine. When dressed again at the end of a week the skin edges are found clean cut, no epithelial growth having taken place from the edges. The floor of the wound has by this time become covered by a closely adherent membrane, only detached with difficulty from the underlying structures. This yellow pellicle forms over whatever tissue is exposed in the wound, whether it be muscle or subcutaneous fat. Experience has shown that a wound heals with much greater rapidity if the flavine be stopped after three or four days in the case of small wounds, and after about a week in the case of severe wounds or compound fracture.

Flavine appears to have many advantages as a primary treatment of recent war wounds. Among the advantages are: (*a*) The absence of all toxicity, even in large wounds. (*b*) The prevention of suppuration and of spreading sepsis. (*c*) The primary dressing need not be changed for two or three days, and is then easily and painlessly removed. This may be of great advantage during severe fighting where rapid evacuation of wounded from front to base is required without unnecessary dressing of the wounds. (*d*) The wounds are not inflamed or painful, and the surrounding skin is never irritated. Flavine cannot be classed as a success in the treatment of the later stages of war wounds. The wounds tend to assume a stagnant condition, during which the processes of repair are almost in abeyance. After a few days, when the danger of gas gangrene and of spreading sepsis have to a great extent passed off, flavine should be stopped and another treatment adopted. In the majority of cases war wounds are not rendered bacteriologically sterile even by the prolonged use of flavine. Test tube experiments carried out with organisms isolated from actual wounds bear out the strong antiseptic properties of flavine, and their enhancement in the presence of serum. Coliform bacilli which are a common infection in the later stages of wounds, are much more resistant to the action of the antiseptic in test tube experiments than any of the other types of organism examined in this way.

29 *Fate of Starch Granules Injected into Rabbit's Vein. M. Okazaki. —p. 101.

29. Fate of Starch Granules Injected into Rabbit's Vein.—Okazaki says that starch granules injected into the rabbit's vein begin to present the glycogen reaction on the sixth day after the first injection of starch emulsion. This reaction can be demonstrated in the granules in the blood and within the histiocyte, but is more marked in the latter. On the basis of these observations Okazaki declares that the histiocyte has a diastatic action converting starch into glycogen.

30. Flying Surgical Unit.—Plisson's proposed *groupe chirurgical mobile* is already working at the front. The principle is to have the operative, the hospital and the administration sections separate, distinct and interchangeable. The operative section is also composed of separate interchangeable parts, each with its truck, one for sterilization, one for the surgical material, one for radiography, and one for the preoperative tent. The hospital section also is divided into interchangeable parts, each with its truck, carrying twenty beds and all other equipments for complete hospital service. The present unit comprises eleven trucks, but more can be added at need as each truck is complete in itself; the personnel of the unit, including the fifty-two nurses, travel by automobiles. This flying unit is thus autonomous and extensible. As it travels on its own power it is independent of traffic, and can be swiftly moved to points where its services are most required.

XIV, No. 2, pp. 113-216

34 *Resection of the Hip Joint for War Wounds. P. Alquier and J. Tanton.—p. 113.

34. Resection of Hip Joint.—Alquier and Tanton give an illustrated description of twelve cases in which from eight to twelve months have elapsed since they resected part of the hip joint above the head, or through or at the base of the neck, or through or below the trochanter. In only one of the twelve cases was the resection primary. In all but two, infection was already installed after the comminuted fracture of the upper end of the femur. Their experience demonstrates that it is possible with an early and complete operation to realize the aseptic healing of a war fracture of this kind. The after care is as important as the operation itself. They get the man on his feet even before the wound has quite healed, the foot hanging loose in a walking cast. If there is danger of talus equinus they have a sole fitted in the stirrup which holds the foot horizontal. A celluloid cast replaces the open plaster cast when the man gets up, and crutches are gradually discarded early. The cases are reported in detail, the outcome justifying the conclusions that even extensive resection of epiphysis and shaft may give good results, the joint solid and free from pain, with possibly some slight functioning of the new joint provided the resection is done at a secondary operation, subcapsular and subperiosteal, at the period of most active bone regeneration. They sacrificed an extent of bone from 12 to 18 cm. long, and their confidence in the ultimate anatomic and functional repair was justified by the outcome in the young men. In only one of their cases was the man left with a loose fibrous pseudarthrosis, and this has been partially corrected by a celluloid corset. The other men with solid ankylosis walk without difficulty; the sole of the shoe on that side is made thicker to balance the shortening of the leg.

40 Choked Disk after War Wounds. A. Cantonnet.—p. 286.
41 Care of the Wounded after Operations. A. Mouchet.—p. 287.

37. War Wounds of the Eyes.—Terrien remarks in the course of this review of ophthalmology in 1917 that the visual disturbances of shell shock are generally transient, but that photophobia, spasmodic myopia, amblyopia or restriction of the visual field may be quite durable. Some think they are of hysteric nature. Vaccination against typhoid may bring on a relapse of iridocyclitis. As the uveal tract is so vascular, it is easy to understand how the vaccination may induce the localization there of casual infection, analogous to the oculoreaction to tuberculin. He has encountered one case of grave purulent iridocyclitis after the vaccination. Sometimes the vaccination started up metastatic ophthalmia, herpes of the cornea or infectious trigeminal neuritis, in those already bearing the seeds of such. Glaucoma secondary to iridocyclitis may rupture under the influence of the reaction to the vaccination. A reaction on the part of the meninges might entail lesions of the optic nerve and tract or ocular paralysis. Morax has warned that a primary acute glaucoma might rupture under the reaction to the vaccine, but he knows of no scientific reason why chronic glaucoma should be aggravated by it. To admit a causal connection, the aggravation must have occurred at the time of or soon after a reaction violent enough to modify the temperature. Ophthalmoscopic and medical examination should precede the vaccination, and he advises exclusion of all with syphilis, tuberculosis, or joint troubles when there is a history of lesions of the uveal tract, especially in persons over 35 or 40. The strict asepsis and antisepsis with war wounds have rendered sympathetic ophthalmia of less frequent occurrence than was anticipated, but a few cases have been encountered. Possibly they might have been more numerous if the patients had been kept under observation longer. A sympathetic reaction is comparatively common, appearing early and disappearing after enucleation. The poisonous drift gases may induce iritis or neuroretinitis, but the course has proved essentially mild.

38. Need for Protection of Soldiers' Eyes.—Terrien expatiates on the importance of a good fitting artificial eye for the later welfare of the wounded, saying that the question of better stumps is growing more and more important as the number of eyes injured beyond redemption is unfortunately increasing every day. This is owing to the more intensive use of grenades and small shells which break up into large numbers of small fragments, and the lack of any device to protect the eyes. No practical means has been found to protect the eyes, and yet, according to his latest notes, 92 per cent. of the perforating injuries of one or both eyes were made by such small flying fragments that the slightest protecting device would have turned it aside and saved the eye. A thin metal shell with a slit permits excellent vision while it would save the eyeball in the majority of cases. The Société d'ophthalmologie adopted in June, 1916, a resolution setting forth the advantages of some such device to protect the eyes, and the authorities conceded the correctness of the principle, but nothing to speak of has been done toward its realization in concrete form. The various measures necessary to ensure a good stump are described in detail, bearing in mind that the withered eyeball itself is the best stump of all.

Presse Medicale, Paris

September 24, XXV, No. 53, pp. 545-560

42 Protection of the Child among the Ancient Romans. IV. E. Jeanselme. Titlepage.
43 *Rebellious Fistulas in the Thorax. L. Bérard and C. Dunet.—p. 545.
44 *Practical Treatment of Syphilis. P. Chevallier.—p. 547.
45 *Tetanus and Tetanophobia. M. Couteaud.—p. 550.
46 *Hot Air Douches in Treatment of War Wounds. J. Bandaline and J. de Polinkoff.—p. 551.
47 *Graduated Spiroscopic Exercises in Training the Respiratory Apparatus. J. Pescher.—p. 552.
48 American Method of Anesthesia by Insufflation. J. Luzoir.—p. 555.

43. **Rebellious Fistulas in the Thorax.**—Bérard and Dunet show by several roentgenograms that often the reason why a fistula persists after a war wound of the chest is that some of the ribs have become soldered together by infected callus. Nothing short of resection of the pathologic tissues will ensure the healing of these fistulas. Roentgenoscopy will reveal the callus and thus permit effectual treatment.

44. **Practical Treatment of Syphilis.**—In concluding this presentation of the present status of treatment of syphilis, Chevallier emphasizes that treatment, even vigorous treatment, which is not kept up for years, does not protect against relapses. He insists that the action of soluble mercurial salts can be only transient. The insoluble salts ward off recurrences better as their action is prolonged longer. Recurring manifestations of the syphilis generally appear first on mucous membrane. The drugs should be given in the largest doses that can be borne without disturbances or only minimal disturbance, and the physician must keep in close touch with the patient. The physician must back up the patient's flagging will, and for this reason among others it is best to give the drugs by injection. The patients generally return to complete a definite course of injections. When it is concluded, he gives a card with the date when the next series of injections has to begin. There is only one contraindication, namely, impermeability of the kidneys. The intervals between courses should never be longer than six weeks. His course of arsenobenzol begins with 0.3 gm. once a week, increasing to 0.75 or 0.9 gm. by the fifth or sixth week and then dropping down again. The rich and the indigent are provided for, he says, but to date no provision has been made for the demi-indigent—those accustomed to paying for medical care at some sacrifice, but unable to bear the expense of four years of treatment. Arrangements must be made for these demi-indigent. Possibly the best plan to avoid infringement on professional secrecy would be to have a dispensary devoted to "chronic diseases"—for all affections which by their persistency condemn the demi-indigent to ruin or abandonment of treatment.

45. **Tetanophobia.**—Couteaud says that in his district every one who gets even the slightest kind of a wound, civilians and soldiers alike, rush to the hospitals for an injection of tetanus serum. The nurses are kept injecting it all the time, so it is flowing in a constant stream. He deplores this as a waste which may deprive the legitimate cases of the precious serum. It is a pity that bacteriologists as yet have been unable to detect in the blood the antitoxic elements which would reveal whether the wounded person is fitted or not to resist the tetanus germs. He is confident that there must be something of the kind, as farmers so seldom develop tetanus although so often exposed to it. We might learn something in this line by comparing the incidence of tetanus after war wounds among soldiers recruited from towns and those from rural districts, whether there is not a professional physiologic vaccination from repeated small inoculations.

46. **Hot Air Douches in Treatment of Torpid War Wounds.**—This communication from a base unit on the southwestern coast reports continued fine results from the jet of hot air turned on lesions in soldiers that refuse to heal promptly, especially the effects of frostbite of the feet and torpid infectious processes in general. The germ count is made before and after the hot air douche, to keep control of the progress, the findings confirming the prompt sterilization of the tissues and the speedy healing thereafter. The importance of having arrangements for aerothermotherapy as an adjunct to every surgical service is emphasized, and an illustrated description of a few cases is given to show the immediate benefit in the relief of pain and the prompt healing of lesions that had been dragging along for months.

47. **Therapeutic Spiroscopy.**—Pescher's spiroscope has already been described in these columns, and he here shows how it can be systematically applied in training the respiration. The long blow tube enters at the side, low down, of a bottle filled with water. The bottle stands on a standard and can be emptied completely at a single blowing by a person with normal lungs. The bottle is graduated, and the individual can see at a glance his respiratory capacity, and can watch it increase as training with this spiroscope expands the breathing area of his lungs. A stopcock on the tube allows the breathing exercises to be graduated for hyperfunctioning. In every case of war wound of the chest, there comes a time when these spiroscopic exercises are extremely beneficial. Also in pleurisy, and especially for persons who seem to be candidates for pulmonary tuberculosis. When the bulbar respiration center has been progressively inhibited by repeated nervous shocks, it may function so sluggishly that the whole system suffers from lack of the normal vigor of the respiratory movements; the resulting anemia, autointoxication or neuropathic depression all show marked improvement under spiroscopic training of the respiratory apparatus. The fact that the patient can see for himself by the drop in the water content of the jar just how he is progressing, gives zest to the exercises.

55 *Suprarenal Symptoms in Malaria. C. Garin, Sarrouy and Pouget.—p. 324.
56 Pathology of the Senegalese Troops Now in France. Ardoin and Bonnette.—p. 326.

50. **Spontaneous Rupture of the Heart.**—Necropsy disclosed that the spontaneous rupture at the apex in a man of 49 was result of infarction from atheroma and thrombosis of the anterior coronary. The man was robust, with no specific pathologic antecedents, but for a few months had had asthma and symptoms of asystole and albuminuria.

55. **The Suprarenals in Malaria.**—Garin and his co-workers report that 4 per cent. of a group of 590 men with malaria presented symptoms showing that the suprarenals had been damaged by the infection. Their extreme pallor and lassitude, blanching of the mucosa, changes in pigmentation, emaciation, anorexia and resistance to the effect of a change to the mountains, testified to the suprarenal insufficiency. The general depression of the whole organism was shown by the tardy recuperation after the attacks, and the slight benefit apparent under tonics until epinephrin or suprarenal tissue tablets were given in addition. The prompt improvement then was striking.

58 War Epidemics of Typhoid Group. D. Olmer.—p. 108.

57. **Deficiency Diseases.**—Weill and Mouriquand's monograph contains an account of much experimental work besides extensive clinical experience. They discuss in detail the deficiency disturbances that developed in pigeons fed with decorticated or sterilized cereals, peas and beans; also the beriberi and experimental scurvy in animals under similar circumstances. They discuss further the deficiency in vitamins or ferment substances in relation to the army ration and the question of bread making. Among their conclusions from this and preceding research are that beriberi cannot be ascribed to decorticated rice alone, as similar hulling of all other grains and legumes is liable to bring on the symptoms of beriberi. Even sterilization of the unhulled grains may bring on the same set of symptoms. The nervous mani-

festations from these deficiency disturbances open a new chapter of pathogenic neurology. They reiterate that "life is necessary to life," and that a rational diet should include the digestible maximum of fresh, "living" foods. The use of ultra refined flour, of sterilized meats, vegetables, milk, etc., kept up too long and too systematically, may be responsible for deficiency disturbances beyond those that fit into the clinical frames of scurvy in young and old, and beriberi.

59 *Dangers and Treatment of Placenta Praevia. A. Labhardt.—p. 1329.
60 *An Embryonal Growth Center in the Crystalline Lens. (Ein embryonaler Kern der menschlichen Linse.) A. Vogt.—p. 1342.
61 *Practical Diagnosis of Duodenal Ulcer. F. Fortmann.—p. 1349.

59. **Placenta Praevia.**—Labhardt reiterates the vital importance of absence of infection when cesarean section is contemplated. Also that cesarean section is the only safe and reliable method for delivering a woman with placenta praevia without injury to the child. Hence the practitioner should get the woman to the hospital as quickly as possible and not allow any internal manipulations, tamponing, etc. All other methods of treatment show a high mortality among the mothers and a frightful mortality among the children, in spite of every effort. To be done under the best conditions, the cesarean section should come early in labor, and the child be extracted before the lower segment of the uterus has been much distended. By this prompt extraction before the placenta becomes separated, we ward off hemorrhage and atony of the uterus after delivery. In the hands of many obstetricians cesarean section has come to have no mortality. It has the further advantage that no germs from the vagina are carried up into the uterus as there is no necessity for version or the inflatable bag. As the uterine vessels are not gaping so much at this time, the danger of air embolism is correspondingly reduced. The general practitioner should insist on the woman's going to the hospital at the first bleedings, whether they occur just before or during labor; he should refrain from internal examination and especially from any tamponing. In the hospital, indications can be met as they arise.

60. **Anatomy of the Crystalline Lens.**—Vogt explains that the posterior surface of the crystalline lens is liable to show grooves and linear elevations indicating some disturbance in growth. There may be whitish lines and other anomalies suggesting an embryonal center of growth. They are found even in children, and he argues that they have something to do with the development of cataract.

61. **Diagnosis of Duodenal Ulcer.**—Fortmann refers to the diagnosis by the general practitioner without laboratory aid, and expatiates on the importance of prompt differentiation of duodenal ulcer. Much loss of flesh and nervousness were prominent symptoms in all his cases, with one exception. One of his patients had correctly diagnosed his own trouble from the clinical picture as he had found it described in a "doctors' book." Blood in vomit or stools may confirm the diagnosis and render radiography superfluous. He advises to have the patient refrain from meat for eight or ten or twelve days before applying the test for occult blood. All such tests have the disadvantage of being disconcertingly sensitive. Repeated negative findings with careful technic are correspondingly instructive as they exclude an ulcer. Hyperacidity is the rule with duodenal ulcer, but anacidity has been encountered by Stierlin and himself, and fluctuating findings in some cases. The practitioner may find Friedreich's swallowed-thread test instructive when the stomach content cannot be obtained directly. He always found the hunger pain, night pain and periodicity of the pains spreading toward the right in the liver region and back. The tender point is two or three fingerbreadths to the right of the median line, outside of the gallbladder, inside of the pylorus point. In one of four cases described in detail, the tender point was to the left of the median line. A second tender point is sometimes found at the end of the right twelfth rib. One of his patients had paid no attention to the pains, which were rather mild, until she had a stool black with blood. Vomiting of blood may occur with duodenal as well as with gastric ulcer. Advanced age does not always turn the scale in favor of cancer; one of his patients was 63, and cases are known with ages older than this. One of his patients, a man of 43, had had symptoms typical of duodenal ulcer for six and a half years when there was severe hemorrhage. There had never been any signs of gastrectasia, but the operation revealed that the ulcer was in the pylorus region. In another case the typical symptoms in a man of 30 had lasted for some time but the stools and radiographic findings were negative. He is evidently a "duodenal-ulcer neurasthenic," and Fortmann remarks that we may expect to encounter such more frequently as the "duodenal triad" is becoming known to the laity.

62 *Intramuscular Serotherapy in Cerebrospinal Meningitis in Children. F. Fanciulli.—p. 1069.

October 11, No. 81, pp. 1089-1096

63 Acute Pancreatitis. M. Maurizi.—p. 1091.

62. **Serotherapy in Epidemic Meningitis in Children.**—Fanciulli remarks that no serum as yet, by any technic, can do miracles, and the fulminating cases terminate fatally as before. But under other conditions serotherapy can be counted on. He tabulates the details of eleven cases in children in which he injected 10 c.c. morning or evening or both, up to a total of 30 or 40 c.c. in the graver cases, with prompt recovery in all but one child who was left with intermittent fever and chills and enlarged spleen. The children were all treated at home, without isolation or disinfection of the premises beyond having the bed linen boiled. There was no second case in any of the families. Another child was moribund when first seen and no attempt at serotherapy was made. He injected the serum into a muscle.

66 Lactic Acid Bacilli Ferments in Therapeutics. G. Monti.—p. 1240.
67 Infant Feeding in Foundling Asylums. O. Viana.—p. 1243.

65. **The Subnormal Arterial Pressure with Abdominal Wounds.**—Chiasserini's long experience with war wounds of the stomach and abdomen has convincingly demonstrated, he says, that the character of the pulse is the guide to treatment, whether to operate or not, and it also affords a basis for the prognosis. He made a special study of the suprarenals from ten men who had died from wounds of the gastro-intestinal tract, securing them a few hours after death. Changes in the suprarenals were constant; they were like those found in diphtheria, all testifying to grave toxic action. When, with an abdominal wound, the pulse is small and fast, and persists thus in spite of measures to combat shock, any operation is contraindicated unless the trouble is from acute anemia. The operation may be successful and the subjective condition good, but the pulse keeps growing worse.

68 *Cause of Persistence of Bacilli in Typhoid Convalescents. L. Preti.—p. 893.
69 War Wounds of the Abdomen. O. Finzi.—p. 894.
70 Diphtheria Antitoxin in Treatment of Epidemic Parotitis. E. Salvaneschi.—p. 896.
71 *Treatment of Fracture of the Femur. B. Schiassi.—p. 897.
72 Present Status of War Psychoneuroses. G. Molinari.—p. 898.
73 *Cinematic Surgery: To Facilitate Vitalization of Artificial Limb. E. Aievoli.—p. 902.

68. **Low Agglutinating Power in Typhoid Carriers.**—Preti tabulates the data in thirty-five cases, showing the agglutination during the typhoid and again late in convalescence. When the agglutinating power from two to nearly five weeks after defervescence was 1:40, bacilli were found in the stools. None were found in the convalescents agglutinating at 1:80, 1:160 and 1:320 with the exception of two cases with

bacilli present the twenty-sixth and twenty-eighth days with agglutination at 1:80. Hence the persistence of the bacilli evidently depends on the proportion of antibodies present.

71. **Fractured Femur.**—Schiassi's "decalogue" as he calls it was summarized, November 24, p. 1835.

73. **Cinematic Surgery.**—Aievoli analyzes what has been accomplished to date in the attempts to make possible the direct control of artificial limbs by traction from muscle fibers. Vanghetti's pioneer work in this line of vitalization of artificial limbs was described recently, page 321.

Rivista di Clinica Pediatrica, Florence

October, XV, No. 10, pp. 505-560

74 *Pathologic Somnolency with Lesion in Midbrain. C. Francioni. —p. 505.
75 *Acetonemia. G. Guidi.—p. 549.

74. **Pathologic Somnolency in Young Children.**—Francioni's patients presenting this mesencephalic syndrome were a child of 3 years and an infant of 10 months. In both the somnolency over months was the most striking symptom, and necropsy in the second case confirmed the diagnosis of a brain tumor. It was found in the isthmus of the brain, a vast destructive lesion shutting off almost completely all connection between the front and the hindbrain. The superior nerve centers were thus apparently cut off from the inferior centers as by a laboratory experiment. Both children were tuberculous, with some tendency to internal hydrocephalus.

75. **Acetonemia in Children.**—Guidi comments on the difficulty at times of distinguishing between acute appendicitis and an attack of periodical vomiting with acetonemia. Palpation of the appendix region through the rectum is sometimes the only means to clear up the case. He advises in case of persisting doubt to remove the appendix. There is always a possibility that the two affections may be associated. Three cases are described in detail in which the profuse elimination of acetone by the breath and kidneys was accompanied by frequent vomiting and occasional severe diffuse pains in the abdomen, the pulse fast and small, and the children were restless and felt badly, and there was no stool. The abdomen was distended but this was uniform, and no specially tender points could be found. While the surgeon was studying the first case with the internist, all the symptoms suddenly subsided. No purgatives had been given but slight peristaltic movements were detected while the abdominal walls were not contracted. The acetonemia subsided under large doses of sodium bicarbonate by the mouth or rectum. There was no movement of the bowel until the fifth day, but by the end of the week the child seemed to be perfectly well again. This child and the second were under 3, the other was 6. This was the first attack of acetonemia in the last two cases; the first child had had at 18 months a similar attack of vomiting with abdominal symptoms. The intestines in the three cases seemed much dilated—evidently a paresis from the toxins in the blood. Guidi has encountered other cases of acetonemia in which there was paresis of the bladder and retention of urine, compelling catheterization, but these disturbances are always transient and disappear with the acetonemia.

Semana Medica, Buenos Aires

August 9, XXIV, No. 32, pp. 149-176

76 *Exclusive Carbohydrate Infant Feeding and Its Evil Effects. M. Acuña.—p. 149.
77 Treatment of Ankylosis by Interposition of Tissue. E. M. Olivieri —p. 153. Continuation.
78 *Charitable Institutions at Buenos Aires. E. R. Coni.—p. 160. To be continued.
79 Ethyl Chlorid General Anesthesia. B. Echevarria, B. D'Ascoli and A. Iturrieta.—p. 162.

76. **Evils from Exclusive Carbohydrate Feeding of Infants.**—Acuña reports two cases of trophy from too exclusive carbohydrate feeding in infants about 6 weeks old, fatal in both. Such children have a good appetite and the digestion seems to be perfect, but they do not increase in weight and height. When they are less than 6 months old, they generally succumb even when changed to breast milk.

78. **The Charitable Institutions of Buenos Aires.**—Coni here gives the first of thirty chapters of his work on the hospitals, asylums and other charitable institutions of Buenos Aires. He says that so much has been done in this line of late years that Buenos Aires now compares favorably with Paris, London, Berlin and New York in this respect.

Nederlandsch Tijdschrift voor Geneeskunde, Amsterdam

September 1, II, No. 9, pp. 751-830

80 The Value of Vivisection for Medical Science. G. van Rijnberk. —p. 755.
81 *Roentgenotherapy of Surgical Tuberculosis. A. van Ree.— p. 767.
82 Enucleation of the Eyeball and Preparation for Wearing an Artificial Eye. H. J. L. Struycken.—p. 779.
83 Experimental Physiology in Relation to Psychology. F. J. Soesman.—p. 781.
84 Medical Statistics and Psychanalysis. D. S. Henkemans.—p. 786.
85 *Congenital Absence of Skin Reflexes and Tendon Reflexes. G. C. Bolten.—p. 788.

81. **Radiotherapy of Surgical Tuberculosis.**—Van Ree gives fifty-seven double illustrations showing the condition before and after roentgen treatment, mostly of tuberculous glands in the neck. In this group of tuberculous glands a complete cure was realized in thirty-five out of forty-eight; only two failed to show marked benefit. The cases showing mere improvement to date may go on to a complete cure in time. One great advantage of the treatment is that the healing proceeds without leaving disfiguring traces. From eight to ten exposures were the average course, some cases needing very few and others requiring a whole year. The exposures were about 4 H. units and the intervals about three weeks. These small doses do not modify the tissues around so as to make operative measures more difficult in case they are deemed necessary later. Tuberculous lesions in small bones healed promptly in seven of his thirteen cases of this kind. In one case of a tuberculous lesion in the sternum, the necrotic masses were excised, followed by smooth and rapid healing under the exposures. The benefit in some cases of bone and joint tuberculosis was so striking that further efforts in this line are encouraged even although this treatment failed in a certain proportion of the old cases, especially in adults. Certain experiences on record warn against exposing the larger joints of children to the roentgen rays as liable to interfere with normal growth later.

85. **Congenital Absence of Reflexes: Skin and Tendon.**—Bolten reported recently the case of an apparently healthy man of 22 in whom neither the knee-jerk nor Achilles reflex could be elicited. There was nothing to suggest tabes, and Bolten accepted the areflexia as a sign of degeneracy. This seems probable also in a second case here described at length. This patient was a woman of 30. She displays a slight neuropathic tendency and is somewhat nervous, but otherwise seems sound. None of the skin and tendon reflexes can be elicited. The periosteum reflexes are faint. As both persons seem normal in every other respect, the anomaly in regard to the reflexes can be explained, he thinks, only by assuming a congenital inferiority, that is, a more or less pronounced degeneracy. There was no trace in either case of hypotony or disturbance in the muscle sense.

Hygiea, Stockholm

86 *Influence of Physical Training on the Morphologic Development of the Motor Nervous System. E. Agduhr.—p. 801.
87 *Influence of Posture on Physical Development of Schoolchildren. T. Resmark.—p. 829.

86. **Influence of Training on the Physical Development of the Nervous System.**—Agduhr reports a pronounced influence from systematic exercises on the development of the motor nervous system of young cats. Other kittens from the same litter had been kept in cages without much chance for exercise, and the difference was marked by the end of seven months. The training of the kittens consisted in their climbing up a long burlap curtain to a graduated height, and repeating at least a hundred times a day. Other tests were made on other warm and cold blooded animals. The findings apparently demonstrate that moderate graduated training of the growing individual causes hypertrophy of most of the

elements of the peripheral motor nervous system, and an increase in the numbers of fibers in the conducting tracts. The brain also grows to be larger than in the controls.

87. **The Habitual Posture of Schoolchildren.**—Resmark measures and compares the findings by means of a frame on a standard. The sides of the frame are marked off in centimeters for the height, and the top and bottom of the frame are marked off to each side from a central zero. The child stands in profile behind the frame, the camera at a fixed distance in front. The research was undertaken to study the influence of the habitual posture on the physical development of the child.

Norsk Magazin for Lægevidenskaben, Christiania

October, LXXVIII, No. 10, pp. 1129-1240

88 *Calcification of the Lungs. F. Harbitz.—p. 1129.
89 Extension Bandage without Plaster. S. Widerøe.—p. 1163.
90 The Heart Complications with Diphtheria. J. Holst.—p. 1167.
91 The Banti's Disease Question. C. Schiøtz.—p. 1176.
92 *Diabetes Insipidus. L. Nicolaysen.—p. 1184.

88. **Calcification of the Lungs.**—Harbitz has previously published some cases of calcium metastasis, calcium gout, and universal calcinosis. He here reviews these experiences and the literature on the subject, and reports the details of a case in which both lungs were so full of calcium that it is surprising that they were able to work at all. The lungs weighed six times the normal weight, and stood up on their own basis. The calcium was evenly distributed throughout, not in deposits around vessels. There had been no preceding destructive bone affection, so the calcification was primary and not metastatic. Six other primary cases are on record which he cites in turn. In his case the kidneys were sound but there had been chronic gastritis with occasional hematemesis. The patient was a woman of 41 with a history of acute articular rheumatism as a child and again three years before, and a chronic tendency to shortness of breath on exertion and to slight cyanosis. She entered the hospital on account of anasarca and ascites; the pulse was 104 and regular, respiration 34 and audible. There were 8,448,000 reds and 11,600 whites. Percussion showed resonance over the lungs with somewhat prolonged expiration and fine crepitation. The woman died in three weeks under the diagnosis of heart disease. The various theoretical possible causes for the extreme calcification of the lungs in this case are discussed, as nothing was found at necropsy to explain it.

92. **Diabetes Insipidus.**—In the first of the two cases reported, a previously healthy woman of 44 developed after her tenth pregnancy a condition of general weakness with tendency to obesity, polyuria, polydipsia and polyphagia. The same set of symptoms was presented by the second patient, a septipara of 34, subject to epilepsy. Tests with pituitary extract and abstention from fluids showed good concentration level. The polydipsia seemed to be primary and there were other features suggesting that the trouble was some disturbance in the centers in the third ventricle.

93. **Carbohydrate Dyspepsia and Xerophthalmia.**—Rønne, as an ophthalmologist, differs from both Bloch and Monrad whose views were recently summarized in these columns, Sept. 29, 1917, p. 1122. He relates that he has had cases of xerophthalmia in infants who had been fed casein and little carbohydrates. He emphasizes that untreated xerophthalmia is practically always fatal. The grave symptoms including the xerophthalmia come on suddenly, suggesting, he thinks, that lack of vitamins is probably responsible. An excessive carbohydrate diet could scarcely induce such a sudden and stormy onset of the xerophthalmia and other symptoms. No instance is known to him of carbohydrate dyspepsia, without xerophthalmia, proving so rapidly fatal. The immediate cause of death is the lowered resisting powers of the child (pneumonia), and he thinks there is much to sustain the assumption that both carbohydrate dyspepsia and avitaminosis are involved. Xerophthalmia is frequently but not always of dietetic origin. It may occur in the tuberculous. Here it seems to depend not on the intake but on the power of assimilation, the inability to utilize the requisite elements although they are supplied in the food. There seems to be an individual power of assimilation, as some children apparently do well on a diet that induces severe xerophthalmia in another.

94. **Prostitution in Wartime.**—Fønss traces the history through the ages of attempts to control the spread of venereal disease, and especially in armies and discusses what is being done during the present war in this line. Among the data cited is Dreyer's statement that 89 per cent. of the registered prostitutes in Berlin gave a positive Wassermann reaction, and Sperk's report that 772 prostitutes who had contracted syphilis were known to have had 2,135 recurrences during the first four years after infection. Fønss mentions that polygamy was introduced in Bohemia after the Thirty Years War. He regards as of great and practical interest the regulations in regard to prostitution promulgated in Austria since the war began. They specify with minute detail the prophylactic measures, the preliminary and terminal salves and rinsings which the prostitute must use herself and offer to her customer. The medical inspector must verify that she has the preservatives, etc., on hand. Fønss remarks that whether the minute directions are followed or not is a question, but the emphasis placed on them by the official decree impresses on all concerned the importance of preservatives.

He relates that the *Dermatologische Wochenschrift* Nos. 11 and 12, 1917, contains the report of a committee appointed by the Reichstag to study the venereal disease question. The main points of the report are the recommendations that professional secrecy should be abrogated when it is a question of venereal disease, that is, the case should be notified by name; that transmission by venereal disease should be penalized; and that the state examination for license to practice should include examination in skin and venereal diseases. Dreuw emphasized that the notification by name is absolutely impracticable unless it is to be made to a central federal bureau which will keep the records for the entire country, and organize uniform measures under the seal of strict secrecy except for the parties directly involved. Fønss adds that compulsory notification to the police of contagious venereal disease is already decreed in Schleswig-Holstein. In No. 9 of the *Wochenschrift*, Hecht published an appeal for the application to prostitution of the principle of the Gøteborg system for reducing the evils of the liquor trade, that is, placing the whole business in the hands of a central organization which aims to make only a small profit on the capital invested. Fønss remarks that this suggestion has much to commend it. It would thus be possible to ensure completely hygienic conditions free from pecuniary speculation. The privately owned brothel, he reiterates, must be stamped out.

Fønss relates that it was not until about 1600 that the connection between prostitution and disease in the soldiers was definitely recognized. Among the efforts to rid the army of the female camp followers he mentions Marshal Strozzi's drowning of 800 at one time in the river Loire (1570), and Gustavus Adolphus' promotion of marriage among his troops (1621). During the Thirty Years War, in 1648, history records that to the army of 40,000 soldiers entitled to rations there were 140,000 followers not on the ration list. The women aided in cooking the food, mending the soldiers' clothes and nursing them when sick. Johann of Nassau proposed in 1608 to substitute men nurses and cooks for women workers, alleging as the chief reason the prevention of infectious diseases. The French commander, Carnot, in 1793 drove away women followers of the camp to the number of 3,000, saying they did ten times more harm to the army than the enemies' guns. Fønss credits most of his historical data to I. Bloch's large work, "Die Prostitution," 1912.

THE TREATMENT OF SOME CASES OF SO-CALLED "PERNICIOUS" ANEMIA

A REGIMEN THAT HAS BEEN FOUND HELPFUL [*]

LEWELLYS F. BARKER, M.D.
AND
THOMAS P. SPRUNT, M.D.
BALTIMORE

"Pernicious anemia," so called, formerly often overlooked, is now generally recognized, when encountered, by physicians who have been trained in the modern methods of examining the blood. Indeed, once the anemia is well developed, the appearance of the patient is so characteristic that its existence is likely to be suspected at first sight before any examination of the blood has been made. In the office of a consulting physician, where these patients are often entering, it is by no means uncommon to have an observant office secretary, who has grown familiar with the pallor, the lemon-yellow tint to the skin, the weakness and the dyspnea, remark that "the patient coming in looks as though he had pernicious anemia."

Though it is easy to place a patient of this sort in a great group designated "pernicious anemia," we know now that this group does not represent a unity. And, of late, we have learned to divide the general group into several subgroups, our classifications being based partly on the blood findings, partly on etiologic considerations. Formerly, it was common to speak of pernicious anemia as a primary or idiopathic anemia, to distinguish it from a secondary anemia due to disease of some organ, to hemorrhage, or to some other known etiologic factor. The terms "primary" and "secondary" anemia are still used, though we now realize that, in the last analysis, there can be no such thing as a strictly "primary" anemia. Again, Ehrlich's attempt to separate pernicious anemia from other anemias on the basis that the regenerative forms of red corpuscles found in the blood are of embryonal rather than of postembryonal type (megaloblasts rather than normoblasts) broke down when it was found that this criterion, though a helpful one, does not admit of strict application. Though no basis of classification of the severe anemias is as yet wholly satisfactory, a separation of those due to increased blood destruction (the hemolytic anemias) from those due to loss of blood by hemorrhage and from those due to defective or decreased blood formation has been found helpful. The old group of so-called "pernicious anemias" contained subgroups belonging to at least two of these categories. Thus formerly the severe hemolytic anemias and the aplastic, or aregeneratory, anemias were lumped together in the pernicious group. By far the majority of cases that were designated pernicious anemia were, however, hemolytic anemias due to increased blood destruction; only a few of them were aplastic anemias due to decreased blood formation. And the matter was further complicated when it was discovered that a hemolytic anemia may sometimes, after exhaustion of the regenerative power of the bone marrow, enter into an aplastic stage. And, finally, an analysis of the severe hemolytic anemias themselves showed that they, in turn, are divisible into further subgroups depending on their etiology. Among these subgroups may be mentioned (1) the hemolytic anemia due to invasion of the intestine by *Dibothriocephalus latus;* (2) the hemolytic anemias due to syphilis, to carcinoma, and to intoxications in the puerperium; (3) the hemolytic anemias due to certain known chemical poisons, as potassium chlorate, nitrobenzene and phenylhydrazin, and (4) the hemolytic anemia that accompanies congenital hemolytic icterus. But after these subgroups had been recognized, it was found that the majority of severe chronic hemolytic anemias still remained unaccounted for, and it has been, and still is, customary to refer to these cases of unknown (or at least unsettled) etiology as "Addisonian anemia," or "Biermer's anemia," or as the "Addison-Biermer type of pernicious anemia."

Without further introduction, we may say that it is the last group of severe hemolytic anemias mentioned, and to it only, to which we shall refer in the present paper. We must agree with William Hunter and other writers who deprecate the use of the ill defined term pernicious anemia, unless, when it is made use of as a designation, the clinical description is such that the reader will have no doubt as to just what the writer means by it. Since the blood picture in the Addison-Biermer type of anemia is indistinguishable from the blood picture of the forms of hemolytic anemia of known etiology, some of which are curable, it is conceivable that still other groups will be separated out from the Addison-Biermer group as soon as their cause has been discovered. Or it may even be that the cases now remaining in the Addison-Biermer group will later be proved to have a single cause (focal infection? enterogenous intoxication?). The disease we are referring to has been so fully described in modern textbooks[1] that no extended account need here be given. It will suffice to recall that (1) it is commonest in people of middle age; (2) the well to do are affected almost as often as the poor; (3) men and women are affected in approximately equal numbers; (4) the onset is, as a rule, insidious, the patients complaining of weakness without apparent cause, of increasing pallor (with straw-colored tint to the skin), of dyspnea, of gastro-intestinal disturbances, and of nervous symptoms; (5) the urine is usually high colored and contains an increased amount of urobilin; (6) there is always gastric anacidity, and (7) the blood changes characteristic of a hemolytic anemia are demonstrable (reduced red count; anisocytosis; poikilocytosis; high color index; often regeneration signs, including nucleated red cells, polychromasic red cells and basophilic stippling; moderate leukopenia with relative lymphocytic increase, and a diminished number of platelets). There is often a little fever, but not always. Numbness and tingling in the hands or feet are not uncommon; in the later stages, the anesthesias, paralyses or ataxias due to the lesions in the spinal cord described by Frank Billings and others may be encountered. Pyorrhea alveolaris, peridental abscesses or other signs of oral sepsis may be present. Remissions in the course of the disease are common. They may occur spontaneously; more often, they follow, and seem to be produced by the application of one or another form of therapy. When a remission occurs, the patient may remain well for months, or even for years. Several exacerbations, separated by remissions, may be encountered in a single patient. Clinical experience teaches us to be very guarded regarding prognosis, for in the majority of cases, sooner or later, a relapse occurs that does not yield to treatment, but goes on to a fatal termination.

UNSATISFACTORY STATE OF PREVIOUS PLANS OF THERAPY

The bibliography of the subject contains great numbers of reports on the various methods that have been used in the treatment of pernicious anemia, and certain of these methods have been, and still are, warmly advocated by their adherents. Their very multiplicity is evidence that in none of them has, as yet, a really satisfactory plan of therapy been found. Indeed, until the etiology and the pathogenesis of the Addison-Biermer type of anemia are better understood, and until more is known of the mechanisms of pathologic hemolysis and of regenerative hematopoiesis, an intirely satisfactory method, applicable in all cases, need scarcely be expected.

Among the forms of therapy that are most in vogue may be mentioned (1) dietetic-hygienic measures; (2) pharmacotherapy (iron, arsenic, quinin, hypophosphites, cholesterin, glycerin, oxygen inhalations, hydrochloric acid, intestinal antiseptics, salt infusions), radium, thorium and the roentgen ray; (3) subcutaneous or intravenous injections of whole or of defibrinated blood; (4) the combating of oral, gastric and intestinal sepsis, and (5) splenectomy.

William Hunter did a great service in emphasizing the importance of not being content with the application of single measures in the treatment of addisonian anemia, urging a "general management of the case, with close observation of all its features, especially of its gastric and intestinal symptoms, of its fever, and of its hemolytic symptoms, extending not merely over the period of acute illness, but also over many months and years subsequent to the first remission."

In this paper we wish to make no extravagant claims for the methods we have employed, but desire simply to set forth a general regimen that, during the past few years, has, when it has been systematically applied, yielded favorable results in at least one group of cases of anemia of the Addison-Biermer type. We say "one group of cases," for we have had other cases that have not responded favorably to the regimen. Why the one set of cases responded whereas another set did not, we do not know. Thus far, we have been unable satisfactorily to differentiate between the two classes of cases before the therapy has been applied.

REGIMEN USED BY THE AUTHORS

1. *The Diagnostic Study.*—When an anemia of the Addison-Biermer type is suspected, the patient is sent at once into a *private room in the hospital,* where the physical examinations and laboratory tests are made with the least possible discomfort to the patient and with avoidance of exertion on his part. If the anemia is severe, we ask the patient to give himself over to us entirely for a time, gaining his *consent to forego both letters and visits,* even from members of his family, for a time. He is required to remain in bed, undressed, constantly, the *rest in bed* being made as nearly absolute as possible, aside from the interruptions necessitated during the first week by the application of diagnostic methods. An experienced *special nurse* is secured whose sole duties consist in administering to the care and comfort of the patient, tactfully securing observance of all directions issuing from the physicians.

After the anamnesis has been recorded, and the general physical examination of the different systems made, the blood, gastric juice, feces and urine are carefully studied and a thorough *search for focal infections* is undertaken. In this search, the special domains of the body known to be prone to focal infection are closely examined, whenever possible by men who devote their whole attention to particular fields. Thus the teeth and gums are inspected by a consulting dentist, expert in oral diagnosis; the extent of any pyorrhea present is reported; roentgenograms of dead teeth are made and the films closely examined for periapical areas of resorption and for paradenal infection. Glossitis, or stomatitis, if present, is carefully noted. A nose and throat specialist is asked to report on the condition of the nose, throat, ears and paranasal sinuses as revealed by direct inspection and by transillumination. In addition, roentgenograms of the paranasal sinuses by the method of Waters and Waldron are made in every case as a supplement to, and control of, the rhinologist's examination. The digestive tract, already studied by physical and chemical methods, is further examined by roentgenoscopy (after barium intake), and if there is any suspicion of ulcer, of appendicitis, of cholecystitis, of ileal or cecal stasis, or of diverticulitis, serial roentgenograms are also made. The urogenital tract is subjected to special examinations also, urethritis, cystitis and pyelitis being sought for in both sexes, in addition to a search for prostatitis and seminal vesiculitis in the male, and for vaginitis, cervicitis, endometritis and pelvic inflammatory disease in the female.

2. *Surgical Treatment.*—In case focal infection is found, even though it appears to be trivial, we usually attempt to eradicate it, for in our experience it pays in the severe anemias, just as in the arthritides, to be radical rather than conservative in the treatment of any infection found.

In the mouth, stomatitis and glossitis receive appropriate local applications; infected teeth are extracted and the sockets are curetted and treated for a few days with iodin solution; gingivitis and pyorrhea alveolaris are treated by a pyorrhea specialist. Any teeth loosened by pyorrhea are extracted. Pyorrheal pockets are carefully curetted and locally treated. After the mouth has been put in good condition, the patient is instructed in the details of a proper mouth toilet, the nurse seeing to it that the technic is acquired and regularly applied.

In the nose, throat and ear, any active infection found is treated at once. For example, a suppurating sinus (antrum, ethmoid, etc.) will be drained; infected adenoids or badly infected tonsils will be removed, though great care should be taken not to subject the patient to an operation on the tonsils merely because they are adherent, or because tonsillitis has previously existed. Here the common sense of the physician in charge may often be required to check the *cacoethes secandi* of an overzealous specialist. Similarly, the best judgment of the physician will be called on in deciding for or against operation for suspected infection elsewhere (gallbladder, appendix, renal pelvis, endometrium, etc.).

In our experience, infections of the teeth and gums have more often than any other infection required immediate attention in pernicious anemia. Rapid improvement has so frequently followed the treatment of such oral sepsis that we cannot help but feel, with William Hunter, that this side of the treatment is, in many cases, very important, and that poisoning from oral sepsis may, in some cases at least, play an etiologic rôle.

It is surprising how well patients with severe hemolytic anemia bear the operations necessary for the removal of foci of infection. At first we were loath to permit even minor surgical operations on these patients, but after a few trials we became convinced that our reluctance had been unfounded. Even with a red corpuscle count as low as 1,500,000 and a hemoglobin of 30 per cent., the patients stand, without harm, a short general anesthesia for extraction of teeth, or for such a procedure as the puncture and cleaning of an infected antrum. It has been rare, too, to see any unusual bleeding follow these minor surgical measures. Should any major operation be indicated, it is best deferred, unless very urgent, until a decided improvement in the condition of the blood has been obtained. Thus one of our patients, who suffered from a cystitis, due to leading a catheter life because of prostatic hypertrophy, came in with a hemoglobin percentage of 38 and a red corpuscle count of 1,400,000. He had several infected teeth, which were removed at once. The blood rapidly improved, and when the hemoglobin had reached 80 per cent., we asked Dr. Young to remove the prostate. The patient bore the operation perfectly well, the cystitis soon cleared up, and he has remained well since.

3. *Dietetic Treatment.*—We believe that attention to the diet of the patient is especially important. Gastro-intestinal disturbances are so common in the disease that they have come to be looked on as more or less characteristic of the symptomatology. Owing to the gastric anacidity there is hypermotility of the stomach, too rapid emptying of that viscus, and frequently diarrhea. The disinfectant properties of the gastric juice are lost, owing to the absence of hydrochloric acid, and abnormal fermentative processes doubtless occur. Eructations, meteorism and general abdominal discomfort are common, and there are sometimes critical exacerbations of these abdominal disturbances. Anorexia is a prominent symptom, and nausea and vomiting are frequently present. It is but little wonder that, as a result of all these conditions, the patients, either on their own initiative, or at the advice of physicians, make attempts to modify their diet so as to secure relief from symptoms. As is well known, these symptoms tend to persist for a time, no matter what kind or quantity of food is ingested. We find that most of the patients that have come to us have reduced their food intake quantitatively far below their needs, and that nearly all are on a qualitatively ill-balanced diet. Moreover, though they may be perfectly willing to rest, their aversion for food and their fear of what may follow eating often make them quite unwilling, and at first even unable, to eat. For this reason, it is our custom to begin, in the severer cases, with the milk diet of Dubois; on the first day we give 2½ ounces of milk every two hours from 7 a. m. to 9 p. m., the two hourly quantity being increased each day until by the sixth day, the patient is receiving some 3 liters (quarts).

On the seventh day, we permit a small piece of bread and a little jam at breakfast time, and at midday we send in a full tray of easily digestible foods. From the beginning, the patient is encouraged to drink all the milk brought to him, regardless of any disinclination he may feel, or of any consequences that may follow it, and the special nurse tactfully but firmly sees that he takes it. Even if there is some vomiting, the milk is given again at the regular times. The same system is followed after the milk diet has been succeeded on the seventh day by a full and varied diet. The patient is encouraged to eat regardless of choice or of inclination, and to empty each dish on the tray. At first the portions sent are not too large, but during the next few days they are rapidly increased in size until the patient is on an abundant roborant diet, rich in protein, and, if he is thin, in carbohydrate and fat also. At this time, too, the patient is asked to swallow a raw egg (with a little orange juice) immediately after each of the three meals. A little later on, two raw eggs after each meal may be given. In our experience, most patients find it easier, when taking three large meals, to swallow the raw eggs immediately after the meals rather than to take them as "intermediate nourishment." Extra milk, too, is given, as far as possible, with meals, rather than between them. Many patients may, within two or three weeks, be induced to take six raw eggs, a quart and a half of milk and a pint of cream, each day, in addition to three full meals. In this way, the daily dietary of the thin patient may easily reach an intake of 4,000 or 5,000 calories. After the first period is over and some gain in strength has been made, an intelligent patient may often be helped, if eating is still hard for him, by giving him a book like Locke's "Food Values," and asking him to figure out, with the aid of the nurse, the number of calories in the diet ingested and to keep a food chart recording the intake of protein, carbohydrate and fat. Interest is soon aroused in securing a gain in weight, as well as in the rising red corpuscle curve and hemoglobin curve after these begin to show improvement. Not a few anemic patients are overweight, and when such obesity exists, we make sure of a large intake of proteins (meat, eggs), green vegetables in purée form, and stewed fruits, keeping the intake of carbohydrates and fats low, in such instances, so that the total caloric intake does not exceed 1,000 or 1,500 calories per day.

The dietetic treatment can be materially aided, also, by measures taken to improve the appetite and to overcome the oral, gastric and intestinal disturbances (see pharmacotherapy).

4. *Fresh Air.*—The windows of the patient's room are kept constantly wide open, though care is taken to insure his warmth in bed. After the diagnostic study has been completed and any preliminary surgical therapy has been got through with, the patient's bed is wheeled out on a porch, where he spends a large part of each day (preferably in the sunshine); in some cases, the patient is encouraged to spend the whole night in the open air, carefully protected from cold.

5. *Pharmacotherapy.*—This plays a subordinate but, in our opinion, a very helpful part in the treatment of a severe anemia. Above all, pharmacotherapy can be a great aid to digestion in patients who suffer from pernicious anemia. On account of the gastric anacidity, we give from 20 to 30 drops of dilute hydrochloric acid (with or without pepsin) with each meal, and the same dose is repeated about half an hour after the meal. Croftan has used even larger doses and, he believes, with good results. In addition, it is our custom to give 45 grains of pancreatin with 45 grains of calcium carbonate three hours after each meal. In view of the fact that hydrochloric acid is absent from the stomach juice and that the pancreatin is further protected by the alkaline calcium carbonate that is given with it, it seems reasonable to assume that much of the pancreatin may pass through the stomach uninjured and reach the intestine in a form capable of aiding in intestinal digestion. Certain it is that many of our patients on this regimen quickly become able to eat large amounts of food, making but few complaints of abdominal discomfort. We regard the hydrochloric acid treatment, however, as much more important than the treatment with pancreatin and calcium carbonate; and when patients, as some will, complain of finding the swallowing of the pancreatin disagreeable, we omit this part of the treatment.

A bitter tonic—say 10 minims of tincture of nux vomica in 1 dram of compound tincture of gentian—given ten or fifteen minutes before each meal may do something toward improving the appetite, though the hydrochloric acid treatment alone, along with the encouraging psychotherapy, is usually followed by a sufficient food intake. The digestive disturbances often clear up in a remarkable way after the measures described have been applied. If they do not, one must keep a close watch for the development of signs of an underlying malignant disease, for, as is well known, a carcinoma of the stomach may for a time masquerade as a pernicious anemia.

Medical tradition as regards the beneficial effects of arsenic in the treatment of these patients we believe to be well founded, and we have used it in every case. Formerly, we used either liquor potassii arsenitis (Fowler's solution) or pills of arsenous oxid and pepper (Asiatic pills[2]), but of late we have given the arsenic in the form of sodium cacodylate, by intramuscular injection. It has seemed to us best to use rather small doses. We give only 50 mg. per dose, once daily for eight days; after an interval of two weeks, a second course of eight injections is given. This does not upset digestion, whereas Fowler's solution sometimes irritates the digestive tract. In a few cases, we have used small intravenous injections of salvarsan (0.3 gm.), and with Byron Bramwell and with T. R. Boggs have felt that it had a good effect; as a routine mode of giving arsenic to these patients, however, we adhere to the intramuscular injection of sodium cacodylate.

6. *Massage; Exercise.*—As we have said, we keep the patients at the beginning of treatment at as nearly absolute rest as possible. This is especially important, if the hemoglobin percentage is very low. A little gentle massage may, however, be started early in the treatment, its amount and force being increased gradually as the patient's condition improves. We usually order it, as a routine measure, to be given three times a week, taking the precaution to engage the services of operators who have been well trained and who have shown, earlier, good judgment in estimating the quantity and quality of massage beneficial at different stages of severe illnesses. The massage is continued as long as the patient is confined to bed.

The patient is not permitted to exercise, even in bed, until the hemoglobin is above 60 per cent.; after that, however, he is instructed in gentle resisting exercises to be taken in bed. The exercises described in S. Bennett's "Old Age: Its Causes and Prevention," are excellent for this purpose. It is a pity that Bennett's book, aside from the description of the exercises, contains much arrant nonsense and misleading advice; if placed in the hands of patients, they should be warned to pay attention in it to nothing but the exercises.

Rest in bed is maintained until the hemoglobin percentage is above 80 and the red corpuscle count above 4,000,000. Toward the end of this period, the patient is allowed to sit up in bed with a back-rest and to occupy himself with reading and with other mild diversions. He is then permitted to sit up in a chair, for one hour on the first day, for two hours on the second and for three hours on the third day. On the fourth or fifth day he is allowed to walk for five minutes. The exercise is then gradually increased until one or two hours of gentle exercise are taken in the open air daily. When the patient leaves the hospital, he is warned of the danger of relapse, is cautioned against excess in mental or physical exertion, and is advised to have his family physician keep a close eye on him even after apparently complete recovery. He is urged to keep up the hydrochloric acid treatment continuously, for the gastric anacidity probably always persists, and he is warned especially against deviating from the well-balanced dietary, arranged in caloric intake according to his needs.

7. *Other Measures, Including Blood Transfusion and Splenectomy.*—In the one group of cases to which we refer, we have usually had a favorable response with no therapy other than the measures outlined above. Some of the patients showed immediate and rapid improvement. A larger number began to show improvement in the blood findings only after two or three weeks of treatment. In many cases, the red count rose to 4,000,000 and the hemoglobin to 80 per cent. within eight or ten weeks. In some cases improvement began only after patient persistence with the regimen for a much longer period. In the group of patients that did not respond at all to this treatment, the blood picture remained unaltered, or grew worse.

---

[2] Asiatic (Tanjore) pills are compounded of arsenous oxid, 5 grains; powdered black pepper, 10 grains; powdered acacia, 3 grains; water, enough to make a mass, divided into twelve pills.

Only after the regimen outlined had been given a thorough trial without benefit did we think it worth while to resort to other measures (transfusions, splenectomy). One exception to this rule has been made: when the red corpuscle count is below 1 million and the hemoglobin percentage below 20 when the patient is first seen, we have found transfusions very useful in raising the blood to a higher level before starting on our usual regimen. When blood transfusions are used, we take especial care to find a suitable donor (negative Wassermann reaction; same group as regards agglutinins and hemolysins).

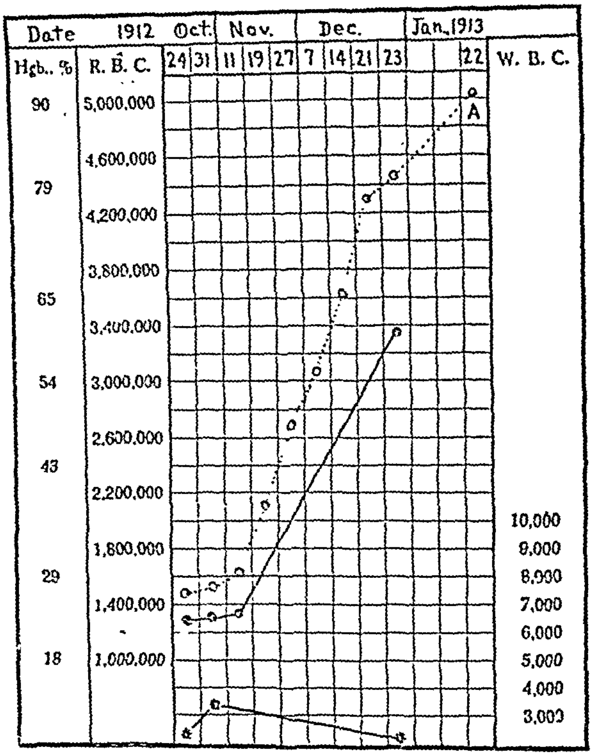

Chart 1.—The blood in Case 1: *A*, reported by home physician. In this and the accompanying charts, the solid line with solid dots denotes red blood corpuscles; the dotted line with hollow dots, hemoglobin, and the solid line with stars, white blood corpuscles.

ILLUSTRATIVE CASES

As examples of favorable response to the method of treatment employed, a few case summaries with blood charts are given. These patients, except in Case 7, are now very well. They all know of the danger of relapse; they are living carefully regulated lives and are having occasional blood examinations made. Patient 7 made a good start, but had a marked setback with fever. Unfortunately, he could not remain at the hospital, but is now trying to gain a remission at his home in a distant state.

Case 1.—*History*.—C. L. M., business man, aged 45, married, admitted, Oct. 24, 1912, discharged, Dec. 23, 1912, complained of indigestion, constipation and "liver trouble." The diagnosis was pernicious anemia, gastric anacidity and oral sepsis. The family history was good. Seven brothers were all well except one, who had had a similar trouble.[3] The patient had had measles, whooping cough and mumps in childhood; pneumonia at 17; tonsillitis at 43; chronic catarrh for twenty years, and otitis media at 30. He was accustomed to three or four colds each year. He had had abdominal pain, coming on occasionally at night, during the past five years; it was relieved by a drink of water. Constipation had been present for three or four years, and hemorrhoids for two years. The patient's habits were good. The onset occurred in November, 1911, one year before admission, with asthenia. The patient stopped work in April, 1912. Other symptoms were loss of weight, anorexia, constipation, and numbness of fingers. Three months before, vomiting spells occurred, with nausea but without pain. His physician said that in August, there was an acute attack with fever, jaundice, choluria, acholic stools, nausea and vomiting, very suggestive of cholangeitis. He had had reverses in business, and was depressed and introspective.

Physical Examination.—The patient was undernourished. There was bronze pigmentation of the skin, and pallor of the mucous membranes; the tongue was flabby and of a brownish color. There were some infected dental roots and a few palpable cervical lymph nodes. The heart and lungs were negative. The liver edge was palpable, two fingers breadths below the costal margin. Slight resistance was encountered in the gallbladder region. There was slight edema of the ankles; a few external hemorrhoids were noted.

The blood picture was that of a severe anemia (Chart 1). There was gastric anacidity. The stools were normal. The Wassermann test was negative. The Calmette reactions were negative.

The only untoward event in his otherwise favorable course was an acute febrile period of four or five hours' duration, with temperature of 102 F., chilly sensations, and nasal discharge. About a month after his discharge from the hospital, his physician, Dr. James A. Work, Jr., wrote that his hemoglobin was 94 per cent. (Gowers). The patient was then feeling well, and was at work. While in the hospital, his systolic blood pressure was about 100; his temperature rose occasionally to 99.5, but usually was not over 99, with a tachycardia of from 90 to 100. Weight increased in the hospital from 120 to 140 pounds.

Treatment.—This consisted of rest, full diet, dilute hydrochloric acid (twentieth normal) before and after meals; arsenic in the form of sodium cacodylate; neosalvarsan (one dose); and, for a time, liquor potassii arsenitis. Blaud's pills were given after meals. A solution of potassium chlorate was used as a mouth wash. The teeth and gums were put in good condition.

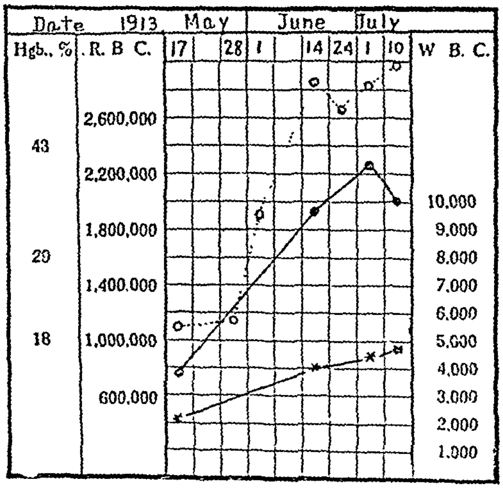

Chart 2.—The blood in Case 2.

This patient, who lives in Indiana, has returned from time to time for observation. He is well and carries on an active business. His hemoglobin has, at times, been as high as 107 per cent.

Case 2.—*History*.—W. C., business man, aged 38, admitted, May 17, 1913, discharged, July 10, 1913, for about eight years, had had a low fever at times accompanied by chilly sensations; the disease had been supposed to be malaria, though the symptoms were much like those manifested on admission. He had been troubled with bad teeth for many years. The present illness had grown worse for four months, with loss of weight, marked asthenia, fever, and tachycardia. On admission to the hospital, several teeth were found to be loose, with pus about their roots. The physical findings and blood picture were typical of pernicious anemia of severe grade. The red corpuscle count was below a million cells; hemoglobin 20 per cent. (Chart 2).

---

[3] This brother, J. H. M., aged 53, came into the hospital the following spring, March 17. He had had bad teeth for eighteen years, typical symptoms of pernicious anemia for nine months, gastric anacidity, blood count of 1,000,000 red blood corpuscles, fever and tachycardia. His course was progressively downward and he died, April 30, in spite of salvarsan, of whole blood subcutaneously, and of a transfusion of 500 c.c. of defibrinated blood.

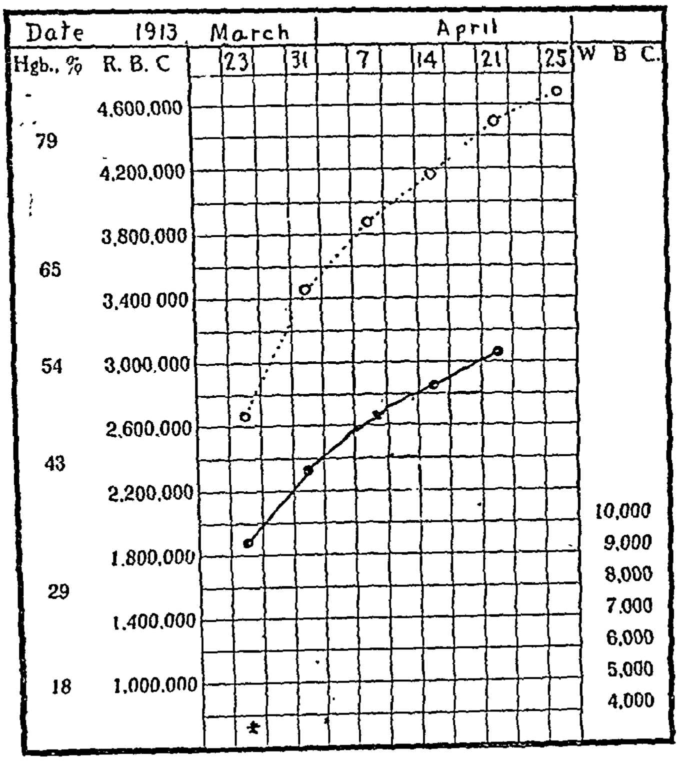

Chart 3.—The blood in Case 3.

Treatment.—This consisted of rest, food, hydrochloric acid, Blaud's pills, and arsenic in the form of sodium cacodylate; neosalvarsan, two doses; and for a time, liquor potassii arsenitis. The teeth and gums were put in good condition by dental specialists.

Note on Discharge.—The symptoms have all cleared up; the patient has gained 12 pounds in weight; the pallor is gone; the blood is rapidly improving.

Case 3.—*History.*—J. C. L., business man, aged 37, admitted, March 21, 1913, discharged, April 25, 1913, complained of a "general tired feeling," nervousness and sleeplessness. The family history was unimportant. The patient's general health had been good. He had had measles and mumps as a child, and gonorrhea, twenty years before admission, followed by stricture of the urethra, which was completely cured. He had a tendency to worry about business affairs, became very irritable at times, and suffered from insomnia. He had meals at irregular times, ate rapidly and, formerly, smoked excessively. The onset began about thirteen months before, following an attack of grip. He did not go to bed, but kept at work, with progressive increase in the asthenia, irritability, insomnia and anorexia.

Physical Examination.—The patient was a well-nourished, muscular man. His face showed marked pallor. The liver edge was palpable 1 cm. below the costal margin. The firm, round edge of the spleen was felt just beneath the costal margin. The blood examination disclosed a moderately severe anemia, with high color-index and leukopenia, as shown in Chart 3. There was gastric anacidity. The Wassermann test was negative. The diagnosis was pernicious anemia gastric anacidity.

once 10. his consisted of rest, full diet, hydrochloric weeks, a secon bonate and pancreatin, 3 drams of each, ch meal, and sodium cacodylate. ge, April 25, the spleen was not palpable. occasional rise of temperature to 99.6 F. There was no fever during the last three weeks. He gained only a few pounds in weight while in the hospital. Later, at a nursing home, he made a good gain in weight. On leaving there, he went to the country to live. His blood is now normal and he is taking up his work again in Alabama.

Case 4.—*History.*—A. E. H., man, aged 43, white, married, admitted, May 18, 1916, and discharged, July 30, 1916, complained of sensitiveness of the plantar surfaces of the feet, and of weakness. The family history was good. He has three children, living and well, and no children have died. The patient has worked hard at confining office work, but his health has been, in general, good. He has had the usual children's diseases. He had influenza four years ago, but has had no sore throat. He has had alveolar abscesses recently. His habits have been good. Patient said his illness began about nine months previously with numbness in hands and, later, in feet and knees. The numbness had disappeared, but he said the toes and the bottoms of his feet were very sensitive. There had been some loss of weight. Blood examined at home had disclosed marked anemia. Three small transfusions of whole blood had been given, each containing from 30 to 50 c.c.

Physical Examination.—The patient was fairly well nourished, though pale and with slightly pigmented skin. The scleras were slightly icteroid. The heart was negative except for a soft systolic murmur. The lungs, the spine and the abdomen were negative. There was definite hyperesthesia on the plantar surfaces of the feet. There were no other evidences of lesion of the nervous system.

The blood revealed the usual picture of a moderately severe pernicious anemia as seen in Chart 4. The Wassermann reaction was negative. The roentgenoscopic examination of the gastro-intestinal tract was negative. After an Ewald test meal nothing was recovered through the tube after thirty-five minutes. There was no fever and no tachycardia. The urine was of low specific gravity, and otherwise normal. Dental consultation and examination revealed periapical areas about three teeth, and these teeth were extracted and their sockets curetted. The diagnosis was pernicious anemia and oral sepsis.

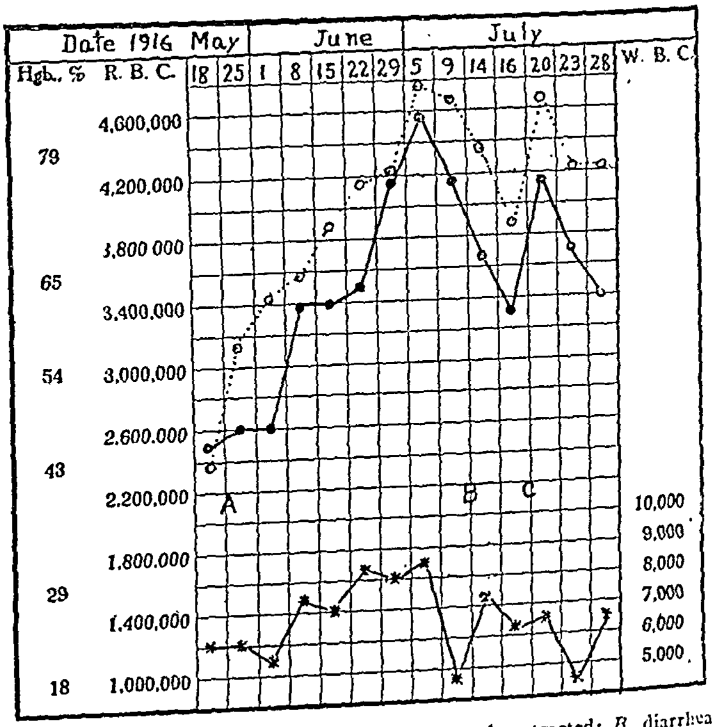

Chart 4.—The blood in Case 4: *A*, three teeth extracted; *B*, diarrhea and abdominal pain; *C*, diarrhea checked.

Our usual regimen for the treatment of pernicious anemia was begun. Improvement began at once, but, after eight weeks, was interrupted by an attack including diarrhea and abdominal pain. After a few days, however, the counts again started upward. Recent reports from his home in Texas state that the patient is very well.

---

2. Asiatic (Tanjore grains; powdered black water, enough to make

Case 6.—*History*.—S. B. F., aged 73, business man, married, was admitted, April 27, 1917, and on examination pernicious anemia and peridental abscesses were revealed. The patient complained of weakness, loss of energy, pallor, dyspnea, and anorexia. He had had one attack of diarrhea. The family history was negative. The patient had had measles, mumps, chickenpox and malaria. He has had a great deal of trouble with his teeth (pain, abscesses). He had an attack of influenza three years ago with bronchitis. He has some frequency of urination, and is unable to empty his bladder. His habits are good. For three years, he had felt loss of his usual energy, and had had vague abdominal discomfort, constipation and anorexia. The weakness had increased steadily and, for one year, had been quite marked. The other symptoms noticed include dizziness, loss of weight, and dyspnea on exertion.

Physical Examination.—The patient showed moderate obesity; had a typical lemon-yellow color of skin and scleras; marked pallor and spade-like hands with abundant soft parts, almost like myxedema. There was severe oral sepsis and tachycardia. A slight pitting of ankles and a slight arterial hypertension were noted. The blood pressure was 150/80.

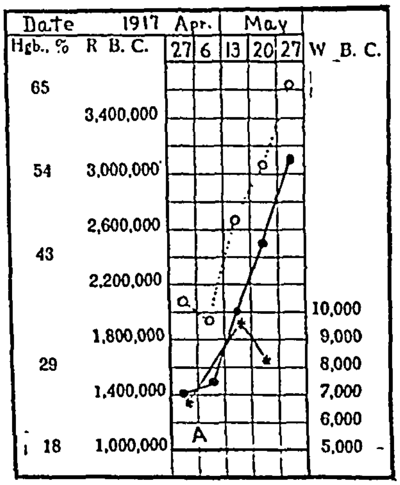

Chart 6.—The blood in Case 6: *A*, extraction of ten teeth, May 4, 1917.

Blood examination revealed a marked anemia as seen in Chart 6. Gastric analysis shows anachlorhydria; total acidity 7 acidity per cent. Stools were small, soft and light yellow, but contained no parasites, ova, or blood. The Wassermann reaction was negative. Dental consultation and examination revealed large periapical areas with pus-sacs about many of the teeth, some ten of which were accordingly extracted.

Roentgenographic examination of the stomach and the intestines disclosed a spastic pylorus and a duodenal cap rotated and flattened out, suggesting a lesion in the neighborhood of the gallbladder. The laryngologic examination was negative. The urologic examination revealed phimosis, chronic prostatitis, and seminal vesiculitis. Further cystoscopic examination will be made when the patient's strength permits. The urine is of normal amount. The specific gravity is 1.015, and there is a faint trace of albumin, hyaline and granular casts, and abnormal amounts of urobilin.

The patient was at first extremely asthenic, and dyspneic on the slightest exertion. These symptoms improved markedly along with improvement in the blood condition. The usual regimen was followed. The chart shows the beginning of an improvement that has continued steadily since. The patient returned to his home in Delaware.[4]

ABSTRACT OF DISCUSSION

Dr. H. A. Christian, Boston: Forced feeding is evidently important, but in our own experience often we have found it exceedingly difficult to carry out because so many patients have nausea or a distinct aversion to food. In overcoming that aversion to food we have sometimes found transfusion valuable. I would suggest transfusion as an appetizer in some of these cases of pernicious anemia. In regard to the treatment with hydrochloric acid, pancreatin and calcium carbonate, we have found great difficulty in getting our patients to take this treatment (on account of the bad taste, especially of pancreatin). We have carried it out as Dr. Barker has suggested, and some patients have taken it very well; other patients have refused. There may be something wrong with our pancreatin, or we lack that persuasive power that Dr. Barker has.

Clearing up foci of infection of course is important. The prolonged rest, with the patient going frequently out into the fresh air or spending the whole day in the open, adds a great deal to the results because the patients take their food so much better, and their general condition is greatly improved. Frankly, however, I do not think we have succeeded in accomplishing much in the attempt, possibly a poor attempt, to carry out the regimen that Dr. Barker has indicated. In some cases we have had good results and in others we have had no results at all.

I should like to emphasize the importance of gastric anacidity in these cases. The point is that sometimes the condition exists for several years before the development of the symptoms of anemia. I have seen a case in which it existed for five years and in one of our cases, which was studied very thoroughly, with a complete blood examination and nothing abnormal made out except gastric anacidity, the patient returned in two years with typical primary anemia. I should like to emphasize the presence of fever as a symptom. As we see it in the hospital, we find fever present with almost no exceptions; if the patient is sick enough to come to the hospital, he almost invariably has fever. These cases have been sent in as typhoid fever and tuberculosis because the general practitioner did not recognize the fever as a symptom of anemia. In these cases transfusion, when it increases the blood, relieves the fever.

Dr. N. E. Brill, New York: I know of no subject in the domain of the pathology of the blood which is surrounded by as much darkness as is the subject of anemia, whether primary or secondary. This is perhaps due to the fact that we as clinicians have not paid much attention to the biologic, physiologic and pathologic conditions associated with anemia. We speak of anemias in a general way as reduction in the number of the red cells of the blood. When we take into consideration the fact that the spleen is constantly destroying blood cells, that the life of a red blood cell, as estimated by Quincke is only thirty days, that therefore of all our blood we are losing one-thirtieth every day, it must strike us that there must be a nice balance between this daily loss and the new red cells formed to keep a constant of 5,000,000 red blood cells to each cubic millimeter of blood. What is the factor that regulates this wonderful balance? For over ten years I have been teaching my students that the regulating cause of this production resided in the red blood cell itself, particularly in its hemoglobin, and was particularly dependent on the oxygen-carrying capacity of the blood. When there is a diminution of oxygen in the blood, whether it be due to deficiency in the number of red cells or in the available oxygen, that deficiency of oxygen is the instigator or the hormone to the marrow for the production of new red cells. Clinically that theory is borne out by many factors. We know that in deficient aeration of the blood such as occurs in emphysema or in cardiac disease, the bone marrow responds to that diminution of oxygen by producing new cells, and polycythemia is a not uncommon accompaniment. Take carbon monoxid poisoning: there is no poison that will dissipate or force aside the oxygen from the hemoglobin as intensely and completely as will carbon monoxid gas, and in every case of this poisoning reported you will find that the bone marrow was distinctly red and that the circulating blood was full of nucleated cells, which means bone marrow activation. Take the blood of people living up on the mountain tops and you will find that the average number of red cells is 6,000,000 instead of 4,000,000 or 5,000,000, which is the number present at sea level, owing to the diminution of oxygen, the result of variation in barometric pressure. Take pernicious anemia, or even Minkowski's disease, in each of which the hemolysis which accompanies them results in the splitting up of the hemoglobin and, therefore, in the oxygen content, as a result of which bone marrow stimulation obtains. Haldane has shown that the blood in pernicious anemia contains the lowest amount of hemoglobin, hence the amount of bone marrow activation is most marked in that disease.

---

[4] In the summer (1917) he wrote that he was well—better than he had been in years.

Dr. George R. Minot, Boston: Dr. George I. Lee and I have studied the anemias at the Massachusetts General Hospital for the past three years, and there is one point about the activity of the bone marrow which was not brought out, yet which seems to us important.

It has been pointed out that the skeined cells (reticulated cells) and polynuclears give us information about bone marrow activity. The blood platelets are formed from the giant cells of the bone marrow and are also important elements to observe when studying bone marrow activity. We feel that if we were given, in a case of pernicious anemia, but one of the three chief marrow elements to judge the activity of the marrow from, we would rather know the number of the platelets than any other single factor.

We have treated approximately 100 patients with pernicious anemia; about 40 of these patients received only fresh air, suitable diet and arsenic; about 40 more have received transfusions, and 19 (chiefly unselected cases) were splenectomized. Splenectomy should, however, be reserved for selected cases, and is to be looked on as only the best means of inducing a remission. It usually gives the most satisfactory results in young patients with large spleens and considerable hemolysis. About 85 per cent. of the splenectomized patients showed some definite improvement following the operation, and 45 per cent. showed marked rapid gains; 50 per cent. of the transfused patients showed definite improvement beyond a simple filling up with blood, and 18 per cent. showed marked rapid gains; while in a similar period of time but 35 to 40 per cent. of the nonsplenectomized and nontransfused patients showed any improvement at all, and 7 per cent. showed marked rapid gains. There was a greater degree of improvement in the transfused and splenectomized than in the other patients.

Dr. Frank Smithies, Chicago: I am glad that Dr. Barker emphasized the important causal relationship of bacteria to the severe anemias. I personally believe that in the majority of these cases of addisonian or "pernicious" anemia we have to deal with a peculiar type of bacterium of the hemolytic group. It is probable that the ailment represents end-results of long continued, intermittently active, low-grade sepsis.

In regard to the treatment, I believe in the early and frequently repeated transfusion of undoubted blood. I think that if we knew how to use transfusion, splenectomy would not be necessary in the majority of cases. Does transfusion do anything? Dr. Christian said that it is an appetizer; it certainly is, in the majority of cases. It will aid Dr. Barker in giving these large masses of pancreatin, which of course physiologically have no action within the alimentary tract. Transfusion will enable the patient to fight infection and its products, and probably stimulate blood formation. It will do in a week what Dr. Barker's rest treatment in bed for a month or more will do. This is an important service when one is treating anemic patients whose time and money are both limited. The individual who is energetically treated from the start has a fighting chance. I think that we ought not to go from this room and say, respecting our addisonian anemias, that the treatment is only "lots of fresh air, good food and sunshine, and Heaven help them." If we let the patient consider that he has a hopeless disease, then he will not do well; but if we get into the patient's mind that there is a cause for this disease and that we are treating that cause as far as possible, we are going to have a fighting group of patients with anemias. Many will get well and be useful citizens.

Dr. Edward Lindeman, New York: The most typical feature of pernicious anemia to me is its atypical and capricious course. One must be constantly guarded lest one attribute to any form of therapy that which rightly belongs to the natural course of the disease.

As to the value of the different measures of treatment as advocated in Dr. Barker's paper, I never give hydrochloric acid, cacodylate of soda or other medicinal remedies mentioned. I do not crowd the food, for the simple reason that after transfusions patients crowd the food without advising it. I do not advise rest in bed after transfusions. Patients are given blood transfusions in quantities from 1,200 c.c. to 2,300 c.c. These transfusions are given by the syringe cannula system and no reactions follow transfusions. Under no circumstances is sodium citrate or other anticoagulant used. I do not find it necessary to transfuse more than once in two months, one and two years, or even longer intervals, depending on the type of case.

When one sees a patient in a semiconscious state with dyspnea, generalized edema, persistent nausea and vomiting, rapid pulse and fever, and four hours after receiving 1,600 c.c. of blood, finds a disappearance of all nausea and vomiting, with the return of full consciousness, with absence, at the end of twenty-four hours, of all signs and symptoms enumerated, and the patient remains well for a period of two years, one cannot help but respect that form of therapy.

In regard to splenectomy, every patient I have had has returned with a blood crisis. What splenectomy has done for some is that it has prolonged the remissions of the disease and only carefully selected cases have proved favorable for this procedure.

In all cases of pernicious anemia coming under my observation in which the patients were in the first year of their disease, and who have remained where I could treat them at opportune times, there has been no death in the last two years. Treatment consisted almost entirely of blood transfusions in large amounts.

Dr. E. L. Tuohy, Duluth, Minn.: I wish to emphasize the value of Schneider's method of estimating pigment output in the duodenal contents. The original investigations of Eppinger and Hess were made on the stools. Splenectomy, as advised by Eppinger, was the outgrowth of this work. Whatever may prove ultimately to be the merits or demerits of this operation, it can be said that certainly splenectomy is not logical in those patients not showing pleiochromia in the duodenal contents. I have studied about thirty cases of severe anemia, using this method in addition to the usual methods of investigation. Interestingly, two cases of *Bothriocephalus latus*, with very severe anemia, did not show any excess of pigment in the duodenal contents. In many severe anemias where I live the patients have shown positive Wassermanns; all of these have shown the same sort of duodenal contents as are seen in the usual severe secondary anemia. All have improved under specific treatment. The true pathology of pernicious anemia still seems obscure. The spleen cannot be looked on as the only destructive agent. These severe syphilitic anemias point to the possibility of striking injury done the bone marrow by syphilitic toxin.

Dr. Alfonso Castelli, New York: In the treatment of secondary anemia, exercise, diet, rest, fresh air and transfusion, of course, give relief, but in my experience in the treatment of secondary anemia the best results have been accomplished by the intramuscular injection of arsenate of iron. Iron, we know, is the time honored drug in the treatment of anemia, and we can trace its use to those early, empiric times when it was obtained for medicinal purposes, from having a red hot piece of iron immersed in water so as to produce aqua ferrata or chalybeate. We also know that iron, which enters into the constitution of the human body, 2.1 gm. being present in the average 65 kg. body, makes hematoblasts become adult erythrocytes, thus entering into the formation of hemoglobin, which is the important functional element in the red cells and the most important *medium* in the *exchange of oxygen* (oxyhemoglobin) from the air to all the tissues.

Arsenic, the well known tonic and alterative, on the other side, seems directly to stimulate bone marrow and the other hematoplastic organs in their blood-cell producing function, and therefore in the combination of the two elements, iron and arsenic, we have an ideal product *with* which to treat anemia. Of course, we know that iron must not be given by mouth, because patients will get either diarrhea or constipation, and we know that the intestines *do not* absorb heavy metals like iron, to say nothing of its teeth-blackening property. Likewise, arsenic tends to show untoward effects—nausea, dyspepsia, gastralgia, etc.—when *administered* by mouth, while the administration *by* the transcutaneous route of the two elements in solution avoids all that trouble and gives, beside, a fair estimation of the *dose* of the compound which is deemed advisable to inject, according to age, size, etc., of the patient. We may start with 0.1 gm. of iron arsenate in 1 c.c. of solution, to be administered every day or every other day, children and undersized patients accordingly, and the dose may be increased up to 0.7 gm. After a number of injections of this arsenated iron the blood picture has become normal, not only in relation to the number of cells, but even to the index of hemoglobin, and the patient who was low spirited, pale, emaciated and underweight when he started the treatment, has regained his normal condition, is feeling well and looking rosy when he has taken the necessary series of intramuscular injections of iron arsenate. This holds good in cases of obscure anemias, as well as in those cases which accompany or follow such diseases as tuberculosis, syphilis, malaria, etc., and in the disorders of metabolism in general.

DR. ALFRED STENGEL, Philadelphia: Hemolysis alone cannot be the basis for our judgment as to methods of treatment. Hemolysis is one factor in true pernicious anemia, and only one. There is the question of marrow activity after hemolysis has been reached, to a certain extent. Observations have been made pointing to specific infection of the bone marrow in some cases. These observations have not been published, but are under way at present. The question of syphilitic anemia, I think, is a proper one. I recall a case of syphilitic anemia of a grade which we see in the most severe pernicious anemia; this patient recovered quickly under antispecific treatment. There are also infectious cases with speedy recovery after removal of the infection.

There are conditions closely resembling pernicious anemia that get well with either Dr. Barker's treatment or Dr. Smithies' treatment; but I am unable to give any positive opinion as to what plan of treatment is going to be effective. I think we are getting nearer to proper treatment in removing subsidiary causes or in coaxing back the bone marrow into its previous activity.

DR. L. F. BARKER, Baltimore: Two points have come out in this discussion: first, the great difficulty in differential diagnosis in some of the cases, and second, the clear advantage in therapy of the removal of foci of infection, and in some instances, of transfusion. As to aversion to food, I believe that we can often do much by urging patients to take food in spite of absence of appetite. Dr. Christian has observed that transfusion increases appetite. In many cases it is necessary to tell a patient that his appetite is not a sufficient guide and that he should eat what the nurse brings him, despite anorexia. An abundant, mixed, roborant diet should be given; the patients should be encouraged to take it and to bear any slight discomfort that follows its ingestion. I agree that pancreatin and calcium carbonate in the amounts mentioned are somewhat unpalatable. We have given them on the theory that, in the absence of hydrochloric acid and of proper secretin-production, some aid to intestinal digestion might be beneficial. Many of us will overlook foci of infection even when we think our search has been thorough.

This brings me to the question of fever. I think it may be due sometimes to the anemia itself, but I think we should first assume that it is due to some focus of infection that we have not yet discovered and we should continue the search for an overlooked focus. If, in a severe anemia, a focus of infection be found, say in the teeth, one might be inclined to say "wait," but I think we should go ahead, give an anesthetic, even to a man with a hemoglobin of 30 per cent., and perform the operation to get rid of the focus of infection. I have done this in several instances with gratifying results. What has been said about transfusion has interested me very much, and I certainly think that patients that do not respond to other methods of treatment should be transfused. I do not want to be understood as being pessimistic about the outlook in even very severe cases, because we now feel that at least many of these anemic patients can be speedily returned to health and to work, and to the enjoyment of life.

Suckers.—We believe that the person who coined the statement, "A sucker is born every minute," sold patent medicines. Cumberland (Md.) *Health Bulletin*.

WOUND INFECTION AMONG LATHE WORKERS

AN INVESTIGATION INTO SOME OF THE FACTORS CAUSING WOUND INFECTION IN INDUSTRIAL SURGERY AND METHODS OF OBVIATING THEM *

MARVIN D. SHIE, A.B.
CLEVELAND

While serving in the emergency hospital of a large manufacturing plant last summer, I was impressed by the great number of infections and cases of furunculosis with which we had to deal. On some men a pinprick, if left unattended, developed into a severe lymphangitis; a slight scratch in twelve hours into a linear mass of pus; a slight abrasion into a suppurating ulcer, and a laceration into a mass of necrotic tissue and pus. There were dozens of cases of multiple furunculosis, some patients developing as many as fifty boils at once on their arms and legs and faces. It is probable that ours was not the only manufacturing plant troubled with experience of this sort, since out of the total amount paid for deaths by the Industrial Commission of Ohio last year, 22 per cent. was for those resulting from infections, and of the total amount paid for disabilities and loss of time, 10 per cent. was for the same cause.

In our plant there are employed about 2,000 men, representatives of many nations—Americans, Canadians, Irish, English, Scotch, Welsh, Swedes, Russians, Poles, Germans, Austrians, Lithuanians, Hungarians, Italians, Armenians, Slavs, Bulgarians, Serbians, etc. Their standards of living vary as much as their nationalities, some of them living in places as crowded, filthy and unkempt as are found in our city slums, others in clean, tidy cottages with little gardens. In age, they vary from 16 to 60. Their general health is good, seeming not to be affected in the least by personal filth or cleanliness. The tenure of employment is exceedingly variable, some men working only a few hours, while others have been with the company for twenty years. The majority of laborers, however, are transient.

Situated on a hill, the plant gets its electric power and water from Cleveland. The plant includes a carpenter shop, old machine shop, new machine shop, structural shop, forge shop, bond room, packing room, pumping station, power house, yard where the structural work is assembled, hospital and offices. Each department has its own toilet rooms, wash rooms and shower baths.

All these departments were represented by patients who came to the hospital. From fifty to sixty patients were seen daily, and of these from 8 to 10 per cent. had furunculosis, and about 5 per cent. had wound infections of various sorts (these percentages are mutually inclusive). It was soon noted, however, that these cases all came from the two machine shops. When this was investigated further, it was discovered that of all the 1,200 or more men in the machine shops, none had multiple furunculosis save those who worked on lathes, and furthermore that 90 per cent. of the infections occurred in men working on lathes. The new machine shop is given over to the manufacture of

---

8-inch shells, and houses about 400 lathes. The old machine shop is given over to the manufacture of machinery of various kinds, and houses only about twenty or thirty lathes. The cases of infections and furunculosis in these two shops varied directly as the number of lathes in each. The men employed on the lathes were of all nationalities and ages, and of the same general health as the rest of the men.

The localization of all furunculosis and the fact that the great proportion of infections was among the lathe workers naturally made us suspect that some element of the lathe work was the causative factor. This was further emphasized by transferring some of the men. Several of those affected with furunculosis were transferred to different types of work in the same and in other departments. In a week the boils began to disappear, and before long the men were comparatively free from them. Likewise some men in other departments, free from furunculosis and infections, were shifted to lathe work. About 35 per cent. of these men developed furunculosis, and in nearly every case, slight wounds which ordinarily would have caused them very little trouble became exceedingly troublesome, requiring constant attention and care to prevent infection. This was considered sufficient proof that lathe work was causing the trouble. The next problem was to discover the troublesome factor.

There were two possibilities: oil and cutting mixture. The oil was suggested by some of the men, and not without reason. For it is a well known fact that employees in machine shops, factories, etc., in which the men come in contact with lubricating oils, which are used automatically again and again, are particularly liable to suffer from dermatitis and furunculosis, in the form of "oil pimples," on the parts of the body which are constantly in contact with the oil. Elsewhere in the shop, however, there were men working in oil who had oil pimples, but whose furunculosis was not nearly so severe, and who were not nearly so susceptible to wound infection as the lathe men.

Cutting mixture is a compound of animal fats, petroleum oils and, as a rule, acids, used to facilitate the action of the cutting tool of the lathe on the object in the lathe. As the work revolves in the lathe, the cutting mixture runs in a steady stream on it at the point of application of the cutting tool. It then runs down over the work and the lathe into drains beneath. These drains empty into a central reservoir, from which the mixture is pumped up into tanks near the roof. With the aid of gravity, the mixture flows from these tanks through the system of pipes to the lathes. Thus the mixture is used over and over until it becomes so dirty as almost to clog the pipes. This, at least, was the condition before our investigation. The men are accustomed to spit into the mixture in the drains beneath their machines, throw their tobacco into it, and otherwise contaminate it. As they work, they are constantly in contact with both the oil and the cutting mixture, with which their clothes are often saturated. Thus it seemed that either might be a fruitful source of infection.

Having determined the possible causative factors, we set about the investigation of each of them. Stained cover-glass preparations, made from the oil and the cutting mixture, showed the presence of cocci and bacilli—very few in the oil and very many in the cutting mixture. Then cultures from each were made on glycerin agar and blood serum, and incubated in an electric incubator at 37.5 C. (99.5 F.). No growth whatever was obtained in the cultures made from the oil, as the tubes were absolutely clean. On the other hand, the cultures made from the cutting mixture were covered with a cream-colored growth in about twelve hours, the glycerin agar having more growth than the blood serum. Smears made from these cultures showed an enormous number of staphylococci, some large diplococci, a few short chains of streptococci, and several strains of bacilli. This was repeated a number of times, and the same results were obtained each time. Plates made from these specimens contained a number of putrefactive colonies, mostly aerobic spore-bearers, and a large number of colonies of *Staphylococcus aureus*. Cultures made from the furuncles and the infected wounds showed the same kind of growth, and the smears showed the same kinds of organisms.

We next tried the effects of inoculation. A series of guinea-pigs was inoculated with suspensions of organisms from cultures made from furuncles and infected wounds, and a second series was inoculated with suspensions from cultures made from the cutting mixture. Three modes of inoculation were tried, namely, scarification, subcutaneous injection and intraperitoneal injection. Other pigs had similar inoculations of distilled water and some had none. These served as controls. The results are shown in the accompanying table.

Ten days later, when the pigs were all apparently normal again, I repeated the experiment, changing the pigs around, and I obtained practically the same results. After another intermission of ten days, I repeated the experiment again, and got practically the same results, though the reactions were less pronounced. Guinea-pigs were rather an unfortunate choice for these inoculations, for I discovered later that they are somewhat immune to staphylococcus infections, and staphylococci made up the greater majority of the suspensions. Considering this immunity, I feel that, since all of the inoculated pigs reacted, the virulence of the organisms was, perhaps, above the average.

These results demonstrated rather conclusively that the cutting mixture was the cause of many of our infections, and also that any harm done by the oil was probably not due to its bacterial content. There was still a possibility, however, that the oil was causing the furunculosis. But "oil pimples," though numerous, do not develop into the large boils, and even carbuncles, with which so many of our patients were affected. The oil might have a local effect, causing irritation and an inflammation which, instead of leading to an effusion of liquid, leads to an emigration of leukocytes, thus producing pustulation, a type of dermatitis venenata. Some drugs possess a specific chemotactic power on leukocytes and thus lead to a septic pus formation. Their injection (hypodermic or into serous cavities) leads to the collection of pus even when asepsis is perfect. Turpentine, croton oil, petroleum, mercury, silver nitrate, digitoxin, cadaverin and a few others are the principal examples. All boils and pimples investigated, however, contained staphylococci. It may be that the constant irritant action of the oil on the skin, following the hairs down into the hair follicles, and setting up an irritation there, caused localized points of lessened resistance which readily succumbed to the attacks of any staphylococci which might later gain access to them. It is not likely that the oil itself is so strongly irritant as to cause furunculosis unaided.

We must consider, then, as causative factors, both oil and cutting mixture, but especially the latter, since our investigations seem to place the greater blame on it.

On inquiry at the Department of Bacteriology of the Public Health Division of Cleveland, I found that specimens had been submitted for analysis from various plants having apparently the same difficulties we were having. Plates made from certain specimens of wash water and lard oil were found to contain a number of putrefactive colonies, mostly of the *Bacillus subtilis* type, together with a few molds. No pyogenic organisms were found. A specimen of alkali water was found to contain 210 colonies per gram, mostly of the *B. subtilis* type, but no pyogenic organisms. A specimen of oil before use contained several putrefactive colonies, but no pyogenic organisms. A specimen of oil after use contained numerous putrefactive colonies and a number of colonies of *Staphylococcus aureus*.

It will be noted that the last of these specimens presented the same bacteriologic findings as did our own cutting mixture. Our oil also showed the same morphologic forms, but the organisms in it did not grow, and so probably were dead.

The portals of entry by which the germs might gain access to the system were many—cuts, abrasions, puncture wounds. Small particles of flying steel from lathes cause innumerable small puncture wounds, each of them sufficiently large to form a portal of entry. We passed the electric magnet over many arms apparently free from steel, and the magnet came away covered with fine steel "hairs" and splinters pulled out of the arms, leaving almost microscopic puncture wounds. We made cultures from the arms of these men, and in less than ten hours the cultures were covered with bacterial growth. Cultures from the arms of twenty-five college students were made in the same way. The majority showed some slight bacterial growth, but nothing approaching that obtained from the arms of these working men. It could not be otherwise, for the arms of the latter were constantly wet with oil and cutting mixture.

EFFECTS OF INOCULATIONS

Method	Time After Inoculation				
	24 Hours	36 Hours	48 Hours	72 Hours	120 Hours
Control pigs	Lively as ever	Well	Well	Well	Well
Cutting mixture:					
Scarified pig	Lively, but seropurulent material along excoriations	More pronounced	Healing	Healing	Healed
Subcutaneous	Decidedly less lively.	Lay inert in corner of cage, under straw; roused with difficulty	Sick, almost comatose	Recovering	Almost well (well in 8 days)
Intraperitoneal	Decidedly less lively.	Inert in corner of cage; under straw; roused with difficulty	Almost comatose	Slightly better	Recovering (well in 7 days)
Wounds and furunculosis:					
Scarified	Very lively, but pus under scabs on excoriations	About same	Healing	Healed	Healed
Subcutaneous	Somewhat less lively.	Very quiet; not easily roused	Inert in corner of cage under straw; roused with difficulty	Slightly better; more easily roused	Much better; practically well
Intraperitoneal	Much less lively	Almost comatose	Slight movement; roused with difficulty	Better	Better (well in 6 days)

PROPHYLAXIS

We next faced the problem of prevention, the prophylaxis. In regard to the oil, about all we were able to do was to try to find men who were more or less immune to its irritant action. There seemed to be no way of counteracting the irritant action without injuring the properties of the oil. With the cutting mixture, however, it was an entirely different problem. This contained living organisms, the main cause of our trouble. The problem, then, was to find some cheap and effective means of killing the organisms without injuring the properties of the mixture. The possibilities were (1) sterilization by heat and (2) disinfection by chemicals.

Sterilization by heat can be carried out in a variety of ways. Probably the most effective method is by circulating steam through coils of pipe placed in the reservoirs and tanks containing the mixture. In this way the temperature attained by the mixture in the tanks is sufficient to kill the organisms present. A disadvantage of this method, however, is that as soon as the mixture leaves the pipe it is so distributed that it at once becomes recontaminated, and therefore reaches the workmen in almost as dangerous a condition as before treatment.

The other method, that of disinfection by chemicals, obviates this disadvantage, since the bactericide is constantly present and renders harmless any organism that might come in contact with it. The selection of the proper germicide for disinfection is really a problem for the makers of the mixture, and as soon as we made them acquainted with the facts, they were glad to cooperate with us and to do all in their power to render the mixture sterile. It may be well, however, to mention some of the difficulties in making a compound of this sort germ-proof. In the first place, it is impossible to use any inorganic or metallic germicide or disinfectant such as mercuric chlorid, copper sulphate, silver nitrate or ferrous sulphate, because of the action of the chemical on the metals with which it would have to come into contact. Oxidizing and reducing agents, hydrogen peroxid, potassium permanganate, sulphur dioxid, ozone, iodin, bromin, chlorin, etc., are ineffective because of their instability and the presence of organic matter in the cutting mixture. Likewise, disinfectants of the fatty series, such as chloroform, iodoform and alcohol are too unstable and also too costly. Some of them would also interfere with the action of the compound. As alkaloids are unsuitable, the only group left is the coal tar series, including phenols and cresols. This group is the least objectionable.

But many members of the coal tar series are also useless for our purpose, for the nature and quantity of the associated material is of great importance and must be taken into account.

Cutting mixture is a more or less oily solution containing considerable organic matter, especially after passing through the pipe and drainage system several times. Phenol (carbolic acid) acts antiseptically scarcely at all when in oily solutions—a fact due to their great solvent power for phenol, and to their ability to prevent its transfer to the bacterial protoplasms. Likewise in the presence of much organic matter, phenol, to be effective, must be used in concentration of about 5 per cent., which is too high a percentage to be desirable from its toxic standpoint. From the standpoint of effectiveness, the degree of dilution of the antiseptic is also important. A 5 per cent. solution of phenol is much more effective than either a 2 per cent. or a 25 per cent. solution. On the other hand, a solution must be strong enough in any given case to be effective. The various antiseptics vary greatly in their effective strength. The element of cost also enters here.

The toxic and corrosivé action of the agent and the ease with which it is absorbed are of importance in deciding its practical usefulness. Some men are susceptible to the odor of coal tar antiseptics such as phenol and cresol, and cannot work with solutions of which these are a part. This is one of the difficulties we encountered. Then, too, the cost of the disinfectant is an important factor, especially in these modern days when manufacturers watch closely every element entering into the cost of production, in order to cut down to the smallest margin the producing cost of the manufactured article.

We have shown that the coal tar disinfectants are practically the only ones available for our purpose. Of these the cresols are of the most importance. They form the major part of crude phenol, and contain the methyl group. This group diminishes its toxicity and increases its antiseptic power. The cresols are about three times as powerful as phenol in disinfecting value. A strength of from 1 to 1.5 per cent. is effective, and is only about one fourth as toxic as phenol. Their cost is also much less than that of phenol. The one disadvantage of cresols is their very slight solubility in water. This insolubility can be readily overcome, however by emulsifying agents. A cresol, then, would seem to be the most practical disinfecting agent for our purposes.

Two methods of sterilization, then, are available: by heat and by chemical disinfection. Both have been tried and found more or less effective. A large foundry about a mile from the plant of which I have been speaking had the same trouble. Here the heat method was used and it was found that the infections and furunculosis were considerably reduced, though not entirely stopped. The chemical method was tried in our plant. Phenol was found to have the disadvantages enumerated in the foregoing. It kept organisms from growing in the mixture only about one and a half days. Next a mixture of phenol and wood alcohol was added to the cutting mixture sufficient in amount to make a 5 per cent. solution when diluted with water. This was found more efficient than phenol alone. Solutions and preparations of cresol were then tried, and it was found that a smaller percentage kept the solution free from living organisms for a much longer time than did phenol, namely, for six days. Another dose had to be added then or else new cutting mixture had to be used to keep the mixture sterile, partly because additions to the number of bacteria in the mixture were constantly being made. This served to reduce markedly the infections and furunculosis, but some of the men could not work with it because of susceptibility to the odor. This is a small matter, however, which may be readily overcome.

It is quite likely that further modifications may be made which will reduce the number of cases still more. For the past three months, the cases of infection have been less than 0.5 per cent., and no complaints are heard from the men regarding either oil or cutting mixture. Whenever it seems probable that living pyogenic organisms are present in the oil, a germicide also might be added to it. We did not try a combination of heat and disinfection, for there was no steam in the shops, all the power being electric. But when steam is available, I believe that a combination of both methods would prove effective, and would greatly reduce the cases of furunculosis and infections, with which the emergency hospitals of many of our large manufacturing plants have to deal. In places where the men are sufficiently intelligent, a program of education in sanitation should be instituted so that the oil and cutting mixture would not readily become contaminated.

SUMMARY AND CONCLUSIONS

1. In a large manufacturing plant the vast majority of cases of wound infections and furunculosis were found to be localized among lathe workers in the machine shops.

2. The peculiar features of lathe work are the use of cutting mixture and oil, and the manner in which these circulate and are used repeatedly, thus making them extremely liable to contamination. This contamination rendered them open to suspicion as factors in the causation of the wound infection and furunculosis.

3. These suspicions were borne out by bacteriologic investigation and animal inoculation, which showed the causative factor to be pyogenic organisms which were present in vast numbers in the cutting mixture and less numerous in the oil. Marked results were obtained.

4. Abundant portals of entry for these organisms were found on the arms of workingmen in innumerable small cuts and punctures made by flying chips of steel from the lathes.

5. The methods of prophylaxis possible are: (*a*) by heat; (*b*) by chemical disinfection, and (*c*) by a combination of the two. Various chemical disinfectants were tried, and the cresol group was found to be the most effective and the least expensive.

6. By use of chemical disinfection (cresols), wound infections have been reduced from 5 per cent. to less than 0.5 per cent. in the plant under consideration, and furunculosis has almost disappeared.

THE FRACTIONAL TEST MEAL

A STUDY OF 377 FRACTIONAL TEST MEALS, OF WHICH 139 ARE IN PROVED PATHOLOGIC CONDITIONS

CHARLES P. HORNER, M.D.
Research Fellow, Wesley Memorial Hospital
CHICAGO

During the past two years there have been 377 fractional test meals given in the Medical Clinic of Wesley Memorial Hospital, under the supervision of Dr. Charles A. Elliott. Thirty of these test meals, as previously reported,[1] were tried on normal individuals, nurses and medical students, eighty-nine on patients in whom the diagnosis has been proved either at operation or at necropsy, forty-five on patients in whom the diagnosis was clinically certain but not proved, and 213 on patients in whom the diagnosis was not absolutely certain and could not be proved.

The present report deals with a total of 139 cases, in sixty-five of which the diagnosis was proved at necropsy or operation and in seventy-four of which there could be no doubt as to the actual condition present. These cases are divided into six groups: (1) diseases of the gallbladder, thirty-eight cases; (2) gastric ulcer, ten cases; (3) duodenal ulcer, twenty-six cases; (4) gastric carcinoma, eight cases; (5) pernicious anemia, eleven cases; (6) miscellaneous, forty-six cases.

The technic uniformly followed was that previously reported (Talbot) from this clinic. In those unusual cases in which the patient found it difficult to swallow the tube, a specially constructed bucket and a tube fitted with a wire obturator, as devised by Dr. Allen B. Kanavel,[2] were employed.

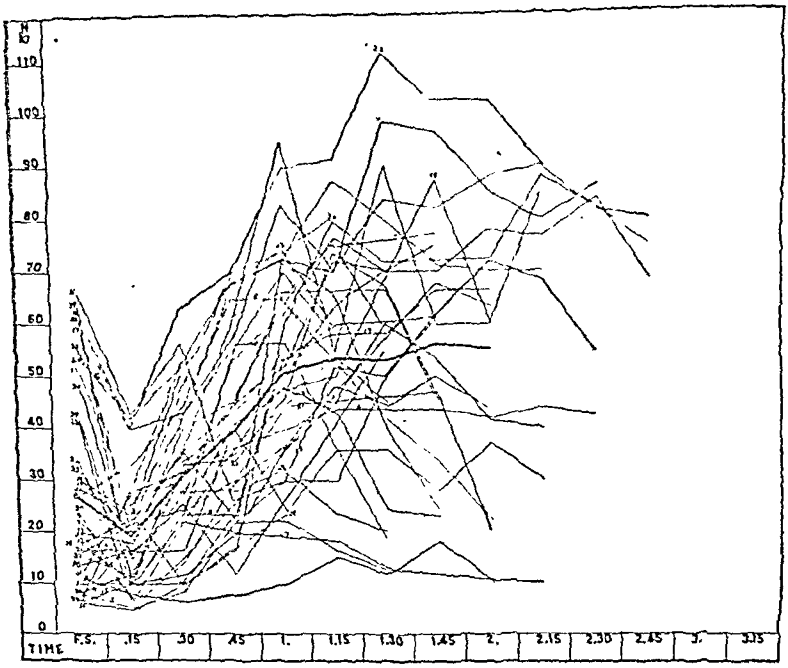

Chart 1.—The total acid curves in thirty-eight gallbladder cases (with operation in thirty-four). Note the low acidity of the fasting content (*F. S.*), the prompt response, the fairly constant time of maximum acidity, and the early emptying time at or near the high point. The gastric cycle is incomplete. In this and the following charts the heavy line represents the mean acid curve and terminates at the mean emptying time.

Special attention was given to the emptying time, first of food and then of secretion, for the two periods do not always coincide. The emptying time was considered of special importance and was well demonstrated by means of the fractional test meal.

DISEASES OF THE GALLBLADDER

This group consists of thirty-eight cases. In thirty-four, the diagnosis was proved at operation, and in four, the diagnosis was conclusive.

Fasting Content.—The amount of gastric content obtained from the fasting stomach varied from 2 to 255 c.c. The latter amount is exceptional, as in only two other cases did the amount exceed 60 c.c. The average was 27 c.c., exclusive of the one exceptional case. Free acid was absent in nineteen cases; below 20 in nine, between 20 and 40 in seven, over 40 in four, with a maximum of 54, the average being 14. The total amount of acid ranged from a minimum of 6 to a maximum of 66, with an average of 29. The highest reading for total acid, in cases in which free acid was absent, was 22. Lactic acid was uniformly absent in twenty-six cases. Gastric mucus was present in excessive amounts in seventeen cases. A benzidin test for blood was positive in three out of thirty-five cases. The microscopic findings were not interesting except in one case in which many pus cells were found in the fasting stomach content. The stomach content for this case gave a positive Gmelin test, and the case proved to be one of cholecystitis, with distention of the gallbladder.

Fractional Meal.—In the acid curve, the beginning of response to the test meal varied in onset from a few minutes to forty-five. In eleven cases it occurred less than fifteen minutes after the test meal, in nineteen cases, between fifteen and thirty minutes after the test meal, and in five it was delayed beyond the thirty minute period. In four cases there was no response. The response, whether prompt or delayed in onset, was gradual in development. The maximum amount of free acid varied from 0 to 80, with an average of 41. For the total amount of acid, the maximum varied from 14, in a case without free acid, to 112, with an average of 60. In point of time, the amount of free acid was highest at from thirty minutes to three hours, averaging one hour and twenty-eight minutes. The high point of total acidity occurred at from thirty minutes to two and one-half hours after the test meal, averaging one hour and twenty-two minutes. For both free and total acid content, the time of the high point was constant, regardless of the promptness of response. This point is illustrated in the accompanying tabulation.

CONSTANCY OF HIGH POINT OF ACIDITY

Cases	Response	Average free HCl	Average total HCl
11	0 to 15 minutes	1 hr. 35 min.	1 hr. 24 min.
19	15 to 30 minutes	1 hr. 40 min.	1 hr. 35 min.
5	30 minutes +	1 hr. 42 min.	1 hr. 36 min.

The type of response is fairly constant in most gallbladder cases. The acid values rise to the high point, at which the stomach empties, the gastric cycle not being completed in twenty-seven of thirty cases. Bile was present in four cases occurring after fairly high acid values were reached. It was accompanied by a decided drop in acidity.

[2] Kanavel, A. B.: Surg., Gynec. and Obst., October, 1916, p. 483.

Pain occurred during the test meal in only one case, was moderate in degree, independent of acid readings, and relieved at the emptying time. The emptying time in the majority, that is to say, twenty-two cases, was between one and one-half and two hours after eating. Only twelve cases continued beyond the two-hour period, and all were empty at the end of two hours and forty-five minutes.

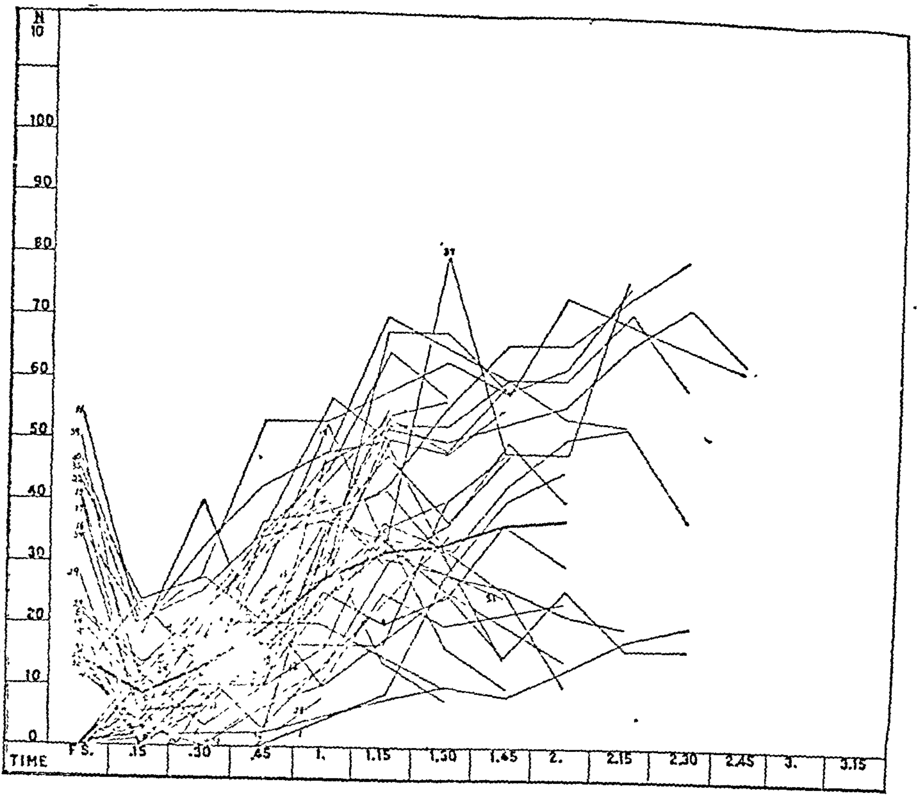

Chart 2.—The free acid curves in thirty-four gallbladder cases (four anacid curves not shown). Note the tendency to empty early at the high point.

Summary.—The characteristic features of the fractional test meal in gallbladder cases are: (1) fairly constant time for maximum acidity; (2) the emptying of the stomach at or near the maximum acidity; (3) early emptying time, and (4) incompleteness of the gastric cycle, interrupted by the emptying process at or near the maximum acidity.

DUODENAL ULCER

In this group, consisting of twenty-six cases, there are fifteen confirmed by operation and eleven in which the clinical diagnosis was certain.

Fasting Content.—From the fasting stomach the amount obtained varied from 5 to 175 c.c., with an average of 50. Eleven cases had less than 30 and eighteen less than 50 c.c., while eight had over 50 and only one over 100 c.c. The free acid value ranged from 0 to 80, with an average of 26. The total acidity varied from 6 to 100, with an average of 43. Five showed a total acidity above 80. Lactic acid was absent in all. Gastric mucus was excessive in seven. Microscopically, food remnants were found in only one, in which the fasting content was 131 c.c., free acidity 70 and total acidity 86. In one, red blood cells were observed with many puss cells, motile bacilli and *Trichomonas intestinalis.*

Fractional Meal.—There was no case of anacidity in this group. In nearly all cases with high acid fasting content, there was a sharp drop in the curve after the test meal was taken. The response to the food stimulus began in seven cases before the fifteen minute period, in eighteen cases before the thirty minute period, and in only one case later than thirty minutes. The response was gradual in development in twenty cases and abrupt in six cases, three of which showed a high acidity in the fasting content. The maximum acidity was reached in from forty-five minutes to three hours after the test meal, with an average time of one hour and thirty-six minutes. Acid values ranged from 24 to 110, averaging 66. The high points of total acidity were 44 to 124, with an average of 85, occurring in from one to three hours after the test meal, the average period being one hour and thirty-six minutes.

While the acme of the curve showed a distinctly high point in nearly all the cases, this level was sustained as a plateau in only five cases. In one there was a drop in the free acid to 0, one hour and fifteen minutes after eating. This was followed by a rise to 42 after two hours and thirty minutes, at which time the stomach emptied itself. In another there were two drops to the 0 line, each accompanied by the presence of bile and followed by a rise, giving the line a triple apex.

In six cases the Gmelin test for bile was positive. Its first appearance was usually accompanied by an abrupt fall in acidity. In one case it was a terminal finding. In three cases it was detected at one point during the test but disappeared, followed by a distinct rise in acidity.

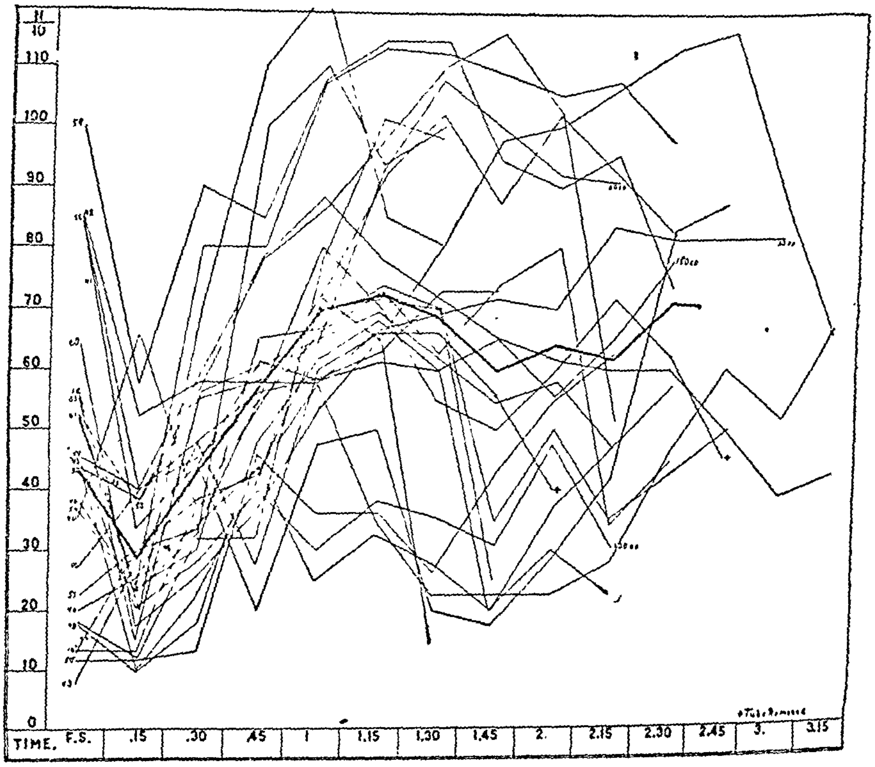

Chart 3.—The total acid curves in twenty-six duodenal ulcer cases (with operation in fifteen). Note the extremes of acidity of fasting content, the prompt secretory response to food stimulus, the high acidity, and the delayed emptying time.

In one case, bile was constantly found from the end of the thirty minute period to the time of emptying, two and one-half hours after eating. In another case, it appeared at the end of one hour after eating, and was constantly present until the stomach emptied at the end of two and one-half hours.

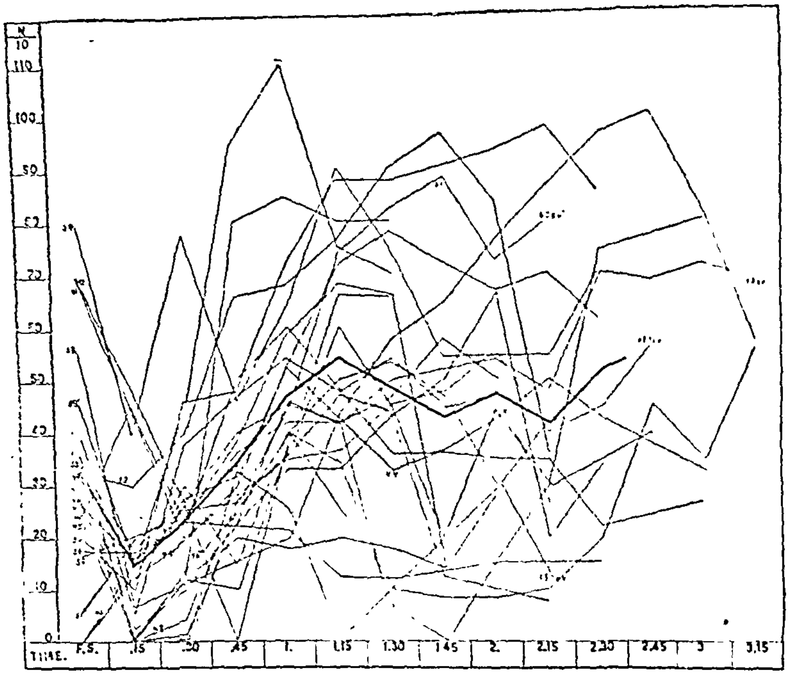

Chart 4.—The free acid curves in twenty-six duodenal ulcer cases (with operation in fifteen). Note the prompt secretory response, the high free acidity, and the delayed emptying time. There are no anacid cases in this group.

In one case, the benzidin test for blood was positive at the apex of the curve. Its appearance was followed by an abrupt fall in the acidity. In this case a chronic ulcer surrounded by many adhesions was found just outside the pylorus.

In eight cases, complaint was made of pain, which, in six of these cases, was described as burning in character and occurred at or just preceding the high acid point, which varied from 54 to 110 free acid. Pain continued until the acidity again fell to a figure corresponding to that at onset. In two cases, the pain was colicky or peristaltic in type, of short duration and with a lower acidity, that is to say, with a free acid content of from 20 to 34.

In this group the type of curve varies greatly, especially in the latter phase, which is most affected by disturbed motility and emptying power. Eighteen cases revealed a normal diverging rise in free and total acid curves, an acute or sustained apex, and a converging decline in acid values throughout the period extending to the emptying time or the discontinuance of the test. In seven cases the decline was abrupt, while in the others it was gradual, varying in length of time, and in some remittent. In six cases the acid values were so sustained and the emptying time so delayed, if, indeed, it came at all, that, in view of the high acid finding in the fasting content, one was justified in classing them as cases of continued secretion. In six cases there was no declining phase, in four cases the stomach emptied at a delayed high point, and in two, a large amount of the content was aspirated at a much delayed point when the test was discontinued.

The emptying time varied from one and three-fourths to three and one-half hours. Food particles disappeared from fifteen minutes to two hours and thirty minutes before the emptying time.

Summary.—The characteristics of this group are: (1) lack of anacid cases; (2) larger amount of fasting content; (3) high acidity, the highest values being found in this group; (4) delayed emptying time, with continued secretion in six cases, and (5) frequency of pain, which occurred in eight out of twenty-six cases.

GASTRIC ULCER

This group consists of ten cases, eight proved by operation and two in which the clinical diagnosis was certain.

Fasting Content.—The amount varied from 10 to 200 c.c., with an average of 65. The amount of free acid ranged from 0 in two cases to 84. In five cases it was more than 50, the average being 35. The total amount of acid ranged from 6 to 97, in five being more than 50, and the average being 51.

The contents were colorless with one exception, which was green and which gave a positive bile test with an excess of mucus and no blood, the ulcer being at the lesser curvature. Mucus was excessive in two cases. Blood was found in none, and bile was present in two.

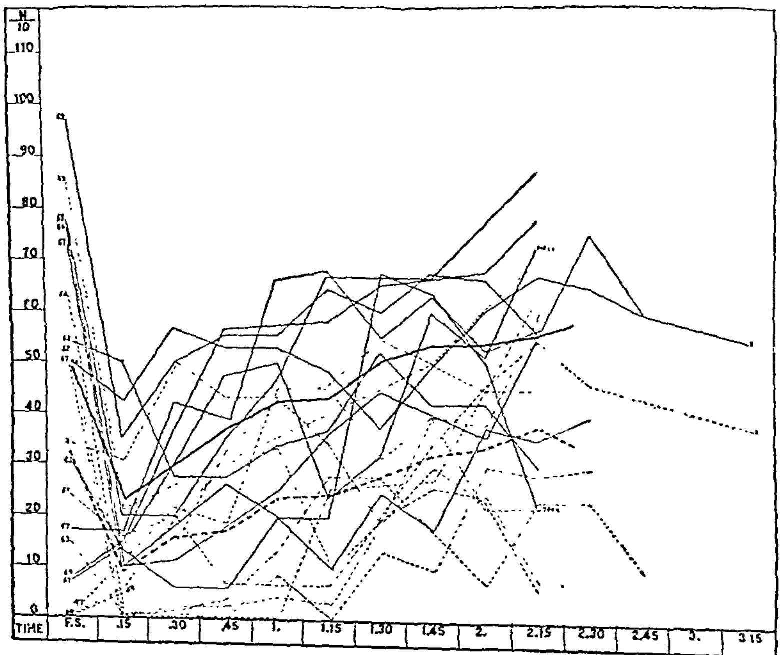

Chart 5.—The fractional test meal curves in ten gastric ulcer cases (with operation in eight). Total acid is indicated by the continuous lines, free acid by the interrupted lines. Note the high acid values of the fasting stomach content as compared with that obtained in the curve, the delayed and weak secretory response, the moderate height of curves, and the fairly uniform emptying time (seven cases at two and one-fourth hours).

Fractional Meal.—Of four cases which revealed high acid findings in the fasting content, the test meal was followed by an abrupt fall in the free acidity to 0 in three, and from 84 to 22 in the fourth. In two other cases the fall was gradual and less in degree. In two cases showing anacid fasting contents, the response was prompt in onset and gradual in development. In two cases the response began between the fifteen and thirty minute periods, in one it was delayed until the end of one hour, and in one there was no perceptible response until the end of one hour and fifteen minutes.

The maximum free acidity was reached at the end of a period varying from one and three-fourths to two and one-half hours, with values varying from 28 to 70, the average time being two hours with 49 acidity. The total acid high point was reached at from one and one-half to three hours, with an average of two and one-fourth hours. The acidity ranged from 40 to 88, the average being 65.

Bile was present in three cases. In one case with an ulcer at the lesser curvature with adhesions, it was present throughout the test, including the fasting content. In another case, bile was present at the end of fifteen minutes after an abrupt drop in acidity from a high fasting point of 62 free and 74 total. In a third case, it was present at the end of the one and one-fourth hour period, accompanied by a prompt fall in acidity.

Blood was demonstrated in only two cases. The pain, which was described as burning, was present in only one case, which showed the moderate acidity of 54 free and 64 total.

Summary.—The characteristic features of the fractional test meal in gastric ulcer are: 1. The amount of the fasting content is comparatively large. 2. The response is weakened and delayed. 3. A high point of only moderate acidity is attained. 4. Free blood and pain during the test are unusual. 5. The emptying time is fairly uniform at two and one-fourth hours, occurring in seven of ten cases.

GASTRIC CANCER

This group consists of eight cases all confirmed by operation or postmortem. The fasting content varied from 10 to 238 c.c., according to the site of the tumor, the largest amount being associated with obstruction at the pylorus. The cases fall into two groups, first, a group of five anacid cases in which there was no response to the test meal, and second, a group of three cases in which there was a response and free acid was present.

Of the five anacid cases the fasting content showed a total acidity of less than 8 except in one case in which the total acidity was 60, on account of the presence of a large amount of lactic acid. There was little or no response. The curve was uniformly flat. The emptying time was early except when associated with pyloric obstruction.

In the three cases in which free acid was present, the acidity was fairly high on the fasting content. In two cases there was a rather prompt response, and the free acid values were fairly high in all. In one case, the high point was reached in thirty minutes, and in the others, at the end of two hours. In one case there was a continued secretion. In all three cases, with free acid present, the pylorus was not involved, the tumors being prepyloric, on the lesser curvature, and cardiac, respectively. The free acidity reached 40, 56 and 74, respectively, the total acid and free acid curves being parallel to each other.

The emptying time was two hours or less in five cases and much delayed in three. Blood was present in five of the eight cases.

Summary.—1. In gastric cancer there are two types of curve, anacid and hyperacid. 2. In the anacid cases, the stomach empties early with one exception, which is associated with an edematous pylorus. 3. There is a continued secretion in two cases in which there is free acid. 4. In all three hyperacid cases, the site of the cancer was at the cardia or lesser curvature, the pylorus being free.

PERNICIOUS ANEMIA

This group consists of eleven cases, in all of which the diagnosis of primary pernicious anemia was clinically conclusive. The fasting content was small in amount, averaging 14 c.c. Free acid was uniformly absent. There was no gastric response to the test meal. In all cases, the benzidin test for blood was negative. The stomach emptied early and the food remained undigested throughout the test in all cases. In only one case was food present at the two hour period, six being empty at the end of one hour.

Three cases of severe secondary anemia resembled primary pernicious anemia, in all of which the etiology was known to be syphilis and chronic hemolytic infection. In two of these cases, the results of the fractional test meal differed markedly from those obtained in the cases of true pernicious anemia, in that the response to the test meal was marked, though somewhat delayed. In other words, free acid values of 35, 40 and 65, respectively, were obtained. In all cases, the response began thirty minutes after the test meal, and the high point was reached at the end of one and one-fourth hours.

Summary.—In pernicious anemia the following conditions were observed: (1) a small amount of fasting stomach content; (2) complete anacidity; (3) absence of blood; (4) unchanged food; (5) early emptying time, and (6) the presence of free acid in severe secondary anemias of known etiology simulating true pernicious anemia.

INFECTIONS

There is a small group of anacid cases of which mention should be made. These embrace chronic infections, such as arthritis, myositis, neuritis, chronic endocarditis, acne and boils. They occurred in patients who complained of no gastro-intestinal symptoms and in whom no acid was found during the fractional test meal. In a case of acne, the eruption apparently cleared up after the systematic administration of hydrochloric acid. Of two patients with hyperacidity occurring in duodenal ulcer, and given ulcer treatment during which the acid was continuously neutralized by the administration of large doses of sodium bicarbonate and magnesium oxid, one developed appendicitis, and the other, multiple acute arthritis. These facts suggest the protective nature of the hydrochloric acid in preventing infective agents from gaining access to the gastro-intestinal tract, or possibly to the general circulation, and would seem to warrant the making of a fractional test in all cases of chronic focal infections of unknown etiology. They also suggest the possible danger of general infection in neutralizing the acid in hyperacid cases.

Two important features of this group of anacid cases are the frequency of gastric anacidity in cases of chronic colitis without gastric complaint, and the value of hydrochloric acid therapy in pernicious anemia. The latter feature, which has been frequently observed in this clinic, also suggests the importance of the defensive rôle of hydrochloric acid as an antiseptic agent in the gastric secretion.

CONCLUSIONS

1. The fractional test meal satisfies the clinician as to the amount and character of the fasting stomach content, the gastric response, the acidity, the amount and character of secretion, the degree of gastric digestion, the presence of blood, the amount of bile, and the pain at any specific point in the gastric cycle, which is of considerable diagnostic value.

2. Certain fairly constant characteristics of the curve are noted in various diseases. In gallbladder disease the secretory response is prompt with high acidity, and the emptying time occurs at or near the high point. In duodenal ulcer there is a prompt gastric response, high acidity and delayed emptying time. In gastric ulcer, not affecting the pylorus, there is a weak and delayed response, moderate acidity and early emptying time. Gastric carcinoma presents two types of curve, the first showing the presence of acid and a delayed emptying time, and the second showing the absence of acid and an early emptying time. Pernicious anemia shows an anacid curve and an early emptying time, while severe secondary anemia shows a definite secretory response and a delayed emptying time. Chronic focal infections may show anacid curves suggesting the gastro-intestinal tract as a possible atrium of infection.

30 North Michigan Avenue.

PROLAPSE OF THE FEMALE URETHRA *

JOHN W. KEEFE, M.D.
Fellow of the American College of Surgeons
PROVIDENCE, R. I.

While a slight amount of eversion of the female urethra is not uncommon, a pronounced bulging or prolapse of the mucous and submucous tissues is fortunately rare. The condition is found with greatest frequency in children, namely, in 60 per cent. of reported cases, while in patients aged from 15 to 40, only 12 per cent. are noted. Again, the percentage rises to 28 per cent. in women affected who are over 40 years of age. The youngest patient mentioned was an infant 5 days old, and the oldest was a woman of 92 years. Debilitated children and old people are those most often affected.

Portions of the mucous membrane removed have been carefully studied by various observers, and in some instances the tissues were found normal, while other specimens examined showed evidences of vascular and inflammatory changes. A number of investigators reported angiomatous nodules with vascular and connective tissue changes. The epithelium had disappeared from some of the projecting angiomatous nodules, which may account for the bleeding which so frequently accompanies this condition. Fibromyomatous changes have also been found with hypertrophied submucous glands.

While these pathologic conditions are of interest, they represent end-results, as they were made from tissues removed when the prolapse was complete, and throw no light on the etiology. The condition of the mucous and submucous structures in the early stages of the prolapse, we have no way of determining.

The large number and variety of theories as to the etiology of prolapse of the urethra is ample evidence that the cause is not definitely known. Among the predisposing causes that have been mentioned are: cough, constipation, straining at stool, trauma, cystitis, vesical tenesmus, stone in the bladder, parturition, angioma and general debility.

Dr. Thomas Addis Emmet, that master of plastic surgery, who gave careful thought to this condition, believed that during parturition, the head of the child pressed forward the loose tissues about the neck of the bladder, and also lacerated the periurethral structures, so that prolapse of the urethra followed. This theory is untenable, as we know that the majority of cases occur in children, and many cases are reported as having occurred in women who have never borne children.

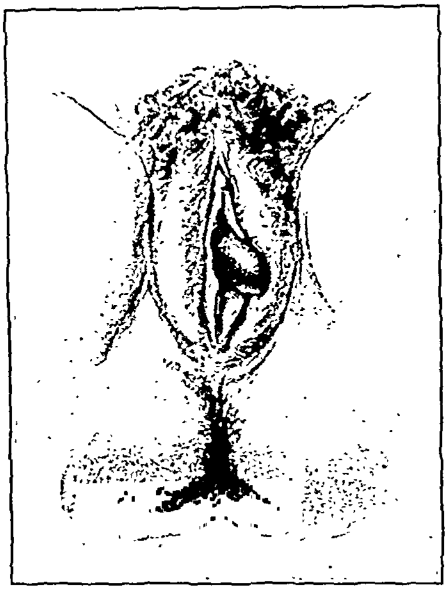

Fig. 1.—Prolapse of the urethra.

I believe that the cause is neuromuscular; that the nervous mechanism that controls the detrusor urinae muscle loses its normal balance and exerts too great a force on the normally loosely attached mucous membrane of the urethra, producing extrusion of this membrane; consequently the constrictor muscle of the urethra becomes partially paralyzed and cannot regain its tone, until the membrane is replaced and held there by the shortening of the sphincter muscles, or by the employment of some other operative procedure.

The symptoms found vary with each case. There may be no discomfort experienced by the patient, and attention is called to the condition solely by the presence of a slight, bloody discharge. Other patients complain of sudden, severe and continuous pain, with vesical tenesmus and frequent micturition. A protrusion can be seen and felt at the site of the meatus urinarius. Ulceration and even gangrene with sloughing of the protruding membrane has occurred.

---

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

Fractional Meal.—Of four cases which revealed high acid findings in the fasting content, the test meal was followed by an abrupt fall in the free acidity to 0 in three, and from 84 to 22 in the fourth. In two other cases the fall was gradual and less in degree. In two cases showing anacid fasting contents, the response was prompt in onset and gradual in development. In two cases the response began between the fifteen and thirty minute periods, in one it was delayed until the end of one hour, and in one there was no perceptible response until the end of one hour and fifteen minutes.

The maximum free acidity was reached at the end of a period varying from one and three-fourths to two and one-half hours, with values varying from 28 to 70, the average time being two hours with 49 acidity. The total acid high point was reached at from one and one-half to three hours, with an average of two and one-fourth hours. The acidity ranged from 40 to 88, the average being 65.

Bile was present in three cases. In one case with an ulcer at the lesser curvature with adhesions, it was present throughout the test, including the fasting content. In another case, bile was present at the end of fifteen minutes after an abrupt drop in acidity from a high fasting point of 62 free and 74 total. In a third case, it was present at the end of the one and one-fourth hour period, accompanied by a prompt fall in acidity.

Blood was demonstrated in only two cases. The pain, which was described as burning, was present in only one case, which showed the moderate acidity of 54 free and 64 total.

Summary.—The characteristic features of the fractional test meal in gastric ulcer are: 1. The amount of the fasting content is comparatively large. 2. The response is weakened and delayed. 3. A high point of only moderate acidity is attained. 4. Free blood and pain during the test are unusual. 5. The emptying time is fairly uniform at two and one-fourth hours, occurring in seven of ten cases.

GASTRIC CANCER

This group consists of eight cases all confirmed by operation or postmortem. The fasting content varied from 10 to 238 c.c., according to the site of the tumor, the largest amount being associated with obstruction at the pylorus. The cases fall into two groups, first, a group of five anacid cases in which there was no response to the test meal, and second, a group of three cases in which there was a response and free acid was present.

Of the five anacid cases the fasting content showed a total acidity of less than 8 except in one case in which the total acidity was 60, on account of the presence of a large amount of lactic acid. There was little or no response. The curve was uniformly flat. The emptying time was early except when associated with pyloric obstruction.

In the three cases in which free acid was present, the acidity was fairly high on the fasting content. In two cases there was a rather prompt response, and the free acid values were fairly high in all. In one case, the high point was reached in thirty minutes, and in the others, at the end of two hours. In one case there was a continued secretion. In all three cases, with free acid present, the pylorus was not involved, the tumors being prepyloric, on the lesser curvature, and cardiac, respectively.

The free acidity reached 40, 56 and 74, respectively, the total acid and free acid curves being parallel to each other.

The emptying time was two hours or less in five cases and much delayed in three. Blood was present in five of the eight cases.

Summary.—1. In gastric cancer there are two types of curve, anacid and hyperacid. 2. In the anacid cases, the stomach empties early with one exception, which is associated with an edematous pylorus. 3. There is a continued secretion in two cases in which there is free acid. 4. In all three hyperacid cases, the site of the cancer was at the cardia or lesser curvature, the pylorus being free.

PERNICIOUS ANEMIA

This group consists of eleven cases, in all of which the diagnosis of primary pernicious anemia was clinically conclusive. The fasting content was small in amount, averaging 14 c.c. Free acid was uniformly absent. There was no gastric response to the test meal. In all cases, the benzidin test for blood was negative. The stomach emptied early and the food remained undigested throughout the test in all cases. In only one case was food present at the two hour period, six being empty at the end of one hour.

Three cases of severe secondary anemia resembled primary pernicious anemia, in all of which the etiology was known to be syphilis and chronic hemolytic infection. In two of these cases, the results of the fractional test meal differed markedly from those obtained in the cases of true pernicious anemia, in that the response to the test meal was marked, though somewhat delayed. In other words, free acid values of 35, 40 and 65, respectively, were obtained. In all cases, the response began thirty minutes after the test meal, and the high point was reached at the end of one and one-fourth hours.

Summary.—In pernicious anemia the following conditions were observed: (1) a small amount of fasting stomach content; (2) complete anacidity; (3) absence of blood; (4) unchanged food; (5) early emptying time, and (6) the presence of free acid in severe secondary anemias of known etiology simulating true pernicious anemia.

INFECTIONS

There is a small group of anacid cases of which mention should be made. These embrace chronic infections, such as arthritis, myositis, neuritis, chronic endocarditis, acne and boils. They occurred in patients who complained of no gastro-intestinal symptoms and in whom no acid was found during the fractional test meal. In a case of acne, the eruption apparently cleared up after the systematic administration of hydrochloric acid. Of two patients with hyperacidity occurring in duodenal ulcer, and given ulcer treatment during which the acid was continuously neutralized by the administration of large doses of sodium bicarbonate and magnesium oxid, one developed appendicitis, and the other, multiple acute arthritis. These facts suggest the protective nature of the hydrochloric acid in preventing infective agents from gaining access to the gastro-intestinal tract, or possibly to the general circulation, and would seem to warrant the making of a fractional test in all cases of chronic focal infections of unknown etiology. They also suggest the possible danger of general infection in neutralizing the acid in hyperacid cases.

case I thought might prove of value in the case of the prolapse of the urethra.

Accordingly I was able to replace by digital manipulation the swollen and prolapsed mucous membrane of the urethra, which formed the tumor. The urethra was found so dilated that I passed my finger into the bladder and could determine that there was no calculus present.

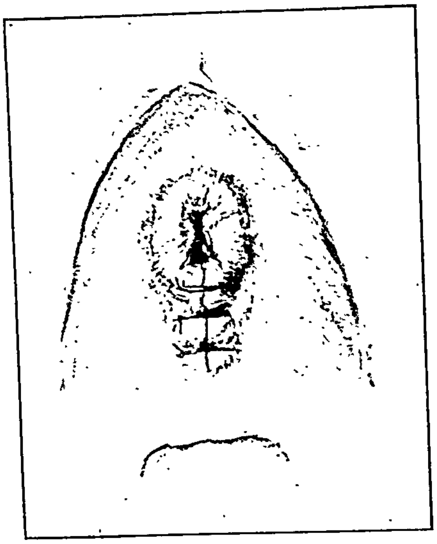

Fig. 5.—Interrupted sutures in mucous membrane.

A vertical incision was made in the lower part of the urethral meatus, through the mucous membrane, muscle and connective tissue. Following the plan that one usually adopts in searching for and bringing together torn fibers of the sphincter ani muscle, in a complete tear of the latter, I picked up with a tenaculum the circular muscle fibers in the right side of the incision and then the circular muscle fibers in the left side. I observed that the diameter of the urethra was lessened when traction was made with the tenacula. A lead probe, about the diameter of the normal urethra, was passed into the bladder, and two chromic gut sutures united the muscle ends tightly about the probe.

A chromic gut stitch was now passed through the muscle, beneath the mucous membrane, the entire circumference of the urethra. The needle entered the wound on the right side, passed in a semicircle and made its exit through the mucous membrane on the upper part of the meatus; reentered the same opening; passed in a semicircle on the opposite side, and made its exit in the left side of the wound. This suture was tied with the lead probe still in position in the urethra, to prevent a too tight closure of the urethra. Four catgut sutures united the edges of the mucous membrane of the wound. The probe was now removed and a Pezzer, self-retaining catheter was passed into the bladder, to permit continuous drainage of that viscus. The catheter was removed the fourth day. The convalescence was uneventful. The patient now has complete control of the urine and has had no sign of recurrence of the prolapse of the urethra.

I have been unable to find mention of this procedure in the literature of this subject.

CONCLUSIONS

1. The cause of prolapse of the urethra is neuromuscular, namely, the loss of balance of the nerve impulses to the detrusor urethral muscle, with subsequent changes in the vascular supply to the tissues, including the adjacent glands.

2. The result is a prolapse of the urethra followed by partial paralysis and relaxation of the constrictor muscles. The treatment should consist in replacing the extruded membrane and shortening the constrictor muscles as described in the case herein reported.

ABSTRACT OF DISCUSSION

Dr. Guy L. Hunner, Baltimore: Dr. Keefe's operation certainly brings before us a simple method of dealing with what can be a very complicated condition, and what has been made a complicated condition in most of our operations in the past. I just asked Dr. Keefe whether he depended entirely on the internal sphincter of the urethra or the external. I thought from his description that he depended on shortening the internal sphincter, but seeing his illustrations made me think he was depending on shortening the external sphincters, and this he says he does. I am surprised that he should get such good results in this way. It seems to me that the same principle applied to the internal sphincter would give more certain results and would be no more complicated. It is really the operation which Hill of Mongomery, Ala., described for the inncontinence sometimes seen after childbirth. Later, Dr. Kelly reported about thirty cases, and Dr. Deaver described the same operation. The operation I have used has an incision down over the urethra to the cervix and lays the anterior vaginal wall wide open. With fine black silk sutures I reach out into the reticular tissues, a second and third bite take up the urethra and the fourth bite reaches out into the opposite side. When the suture is tied it not only tends to shorten the fibers themselves, but it infolds the urethra. The operation is generally followed by a perfect result. I have had three partial failures in about thirty cases. This operation involves about the same principles that Dr. Keefe has described, but it deals with the internal sphincter.

Dr. Brooke M. Anspach, Philadelphia: I take great interest in Dr. Keefe's operation because I have been using a method somewhat like it in connection with other plastic work. In cases of cystocele with relaxed pelvic floor in old women, one often finds a large, gaping urinary meatus. By inserting sutures through the tissues at the neck of the bladder as Dr. Kelly has described, the internal sphincter is tightened and by resecting the anterior orifice very much after the manner illustrated by Dr. Keefe one can turn in the exposed mucosa. I think this plan makes satisfactory control of the bladder even more certain and it relieves the women of the irritation and pain which they often have from the exposed mucosa.

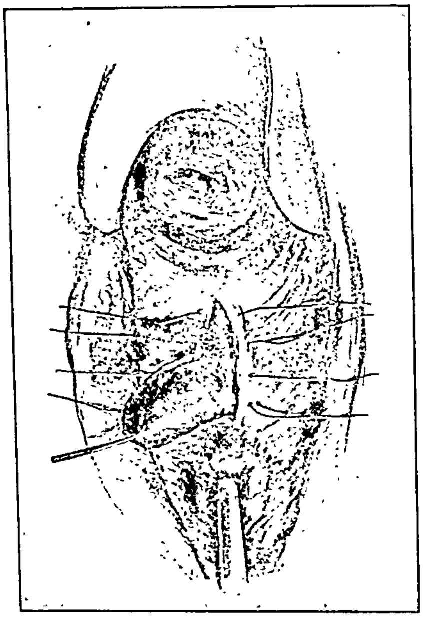

Fig. 6.—Dr. Emmett's buttonhole operation.

Dr. John W. Keefe, Providence, R. I.: The operation described by Dr. Hunner, to my mind, is of value, and in some of the aggravated cases may be preferable to the operation I have described. The muscular structures about the female urethra are in excess near the bladder and near the meatus, but there are circular muscles all the way along the urethra, besides the longitudinal muscles. The muscular structure just back of the meatus is so well developed that it alone, as has been proved by the case reported, may be sufficient to control the flow of urine. If this is so, it seems to me that the simpler the operation the better; but, if there should be a recurrence, I think then some operation on the internal sphincter or the portion of the circular muscles near the bladder may be of value. If, however, the simpler operation is sufficient, it is better, whenever possible, to employ this method.

THE PRESERVATION OF THE MENSTRUAL FUNCTION

IN DOUBLE SUPPURATIVE DISEASE OF THE TUBES AND CHRONIC METRITIS *

JOHN OSBORN POLAK, M.D., M.Sc.
Fellow of the American College of Surgeons
BROOKLYN

The proper management of suppurative tubal disease in the young woman often taxes the judgment of even the experienced surgeon. When to operate, so as to afford the patient the greatest margin of safety, and how to operate, to obtain the best end-results, are questions that should be definitely settled. On these questions the surgeon and gynecologist, however, seem to hold different views. The gynecologist has learned from bitter experience that time alone sterilizes the tubal content and that when sufficient time is allowed, Nature is competent, to a considerable degree, to absorb and regenerate the function of many of the involved structures. We have also learned that different bacteria, each having a different life history, have a decided influence on the operative prognosis.

Simpson and I have promulgated and taught these rules as to the time for operation: 1. Radical abdominal procedure should never be done in the presence of acute tubal infections, or in acute exacerbations of chronic inflammatory conditions. 2. It takes time to sterilize the tubal content — from six weeks to three months in gonorrheal infections, and longer when the streptococcus is the infecting agent. Hence, a greater period of quiescence is necessary after postabortal infections, than when the clinical course points to the gonococcus as the causative agent. 3. The morning and evening temperature must be normal for a period of at least three weeks before intervention is considered. 4. Bimanual examination of the pelvic organs must show the exudate to have disappeared, or if an exudate is present, it should be hard and insensitive and the pelvic manipulation should not be followed by an exacerbation in temperature or leukocytosis or local sensitiveness, for unless the exudate is quiescent, manipulation will squeeze the toxins into the surrounding lymphatic channels and occasion a fresh resistive reaction. Hence the importance of making comparative leukocyte and differential counts before and after bimanual examination in pelvic inflammations, for by this method we may determine the state of their activity. 5. No patient should be operated on by the abdominal route unless the leukocyte count remains at a point under 11,000, and the polymorphic leukocytes at 75 per cent. or less. Success or failure depends directly on the observance of the foregoing principles, for unless Nature has had time for resorption of the exudate and regeneration of the pelvic tissues, conservation of any of the pelvic structures is out of the question.

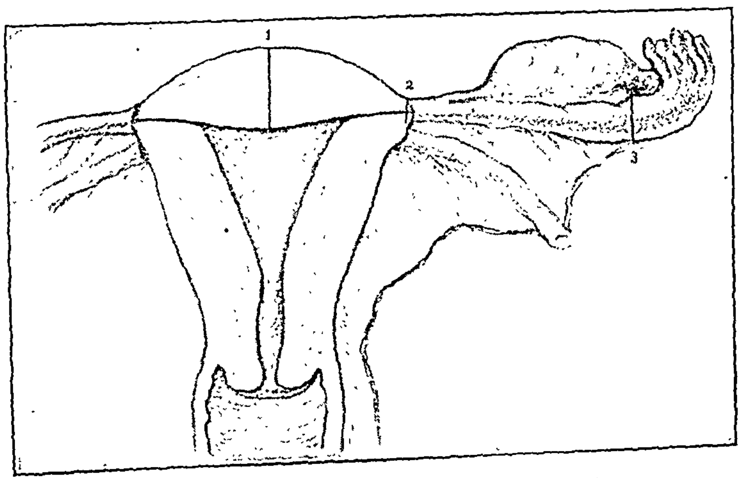

Fig. 1.—Location from which sections were taken.

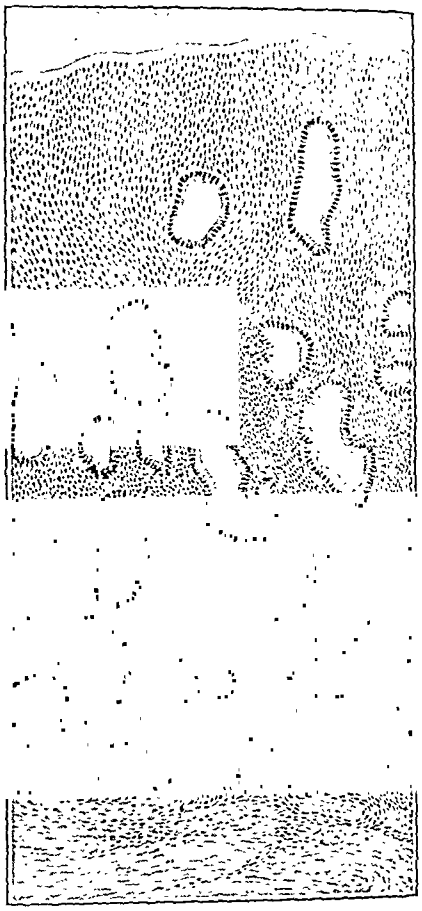

Fig. 2. — Normal endometrium from fundus uteri.

Infection of the tubes, resulting from an extension of the inflammation through the uterus, is usually bilateral, for gonorrhea involves the entire tube; hence any attempt at conservation offers but little protection against subsequent exacerbation. All of us have seen cases with one tube grossly involved, while the other, macroscopically at least, was free from disease, yet during convalescence, or while the patient was still in the hospital, the retained tube would light up and become a thick, swollen mass, adherent to the posterior surface of the uterus. It was formerly supposed that no fluid accumulation could occur in the tube until both ends were sealed, but by making serial sections through the isthmian and interstitial portions of the tube in a large series of cases, we have found that the uterine end never closes and that the apparent occlusion in the isthmian and interstitial portion is relative and not actual. This may be explained by the fact that the folding, edema and consequent swelling of the mucosa make the actual lumen so tortuous that intratubal pressure closes, or practically closes, the uterine end. If one recalls for a moment the anatomy of the interstitial portion of the tube, surrounded as it is with an inner circular muscular coat, which is continuous with the circular muscular coat of the uterus, one must be impressed with the fact that any inflammatory process of the mucosa must excite an inflam-

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

matory reaction in the submucous and muscular structures immediately surrounding the mucous tube. The muscular coat, when examined microscopically, is edematous and infiltrated with inflammatory tissue cells, and in the mixed infections, particularly when the streptococcus is present, there may be found small localized abscesses in the surrounding muscle tissue. This small round tissue cell infiltration results in an increase in the connective tissue within the uterine wall and thereby actually increases the size of the uterus. Such metritic changes do not subside after the removal of the distal portion of one or both tubes.

The persistence of this infection of the uterine muscle formerly tempted the French operators to do vaginal hysterectomy with double salpingectomy, for chronic suppurative tubal infection. Many of our more conservative surgeons acknowledge that a gonorrheal infection of the tube can never be wholly cured without ablation of both tubes, and that the persistent leukorrhea, which under certain excitation regains its infective properties, and the increased amount of the menstrual flow, which with the pelvic pain makes up the clinical syndrome in these cases of chronic inflammation, are due to the enlargement and increased blood supply to the metritic uterus, and because of the persistence of these symptoms, have advocated hysterectomy when salpingectomy is done, with the retention of one or both ovaries.

While we are agreed that the retention of an infected uterus is a menace to the woman's future health, my own feeling has been that when *so much care is taken to preserve the function of ovulation, there should be like care in preserving the function of menstruation,* as ovulation without menstruation contributes little to the patient's well-being. Sections through the uterus, between the fundus and the internal os, show few if any of the pathologic changes which may be demonstrated about the pars interstitialis. It is only in the cervical region, in Naboth's glands, in the columnar epithelium of the cervical canal, in the fundal region, and in the structures surrounding the pars interstitialis that there is a persistence of the inflammatory changes described above. Therefore, it must appeal to any one of considerable clinical experience that, in a given case of chronic specific infection involving the cervix and the tubes, a cure cannot be effected, except by the removal of these foci, and to attain this end many are doing panhysterectomy. The endocervicitis and cervicitis may be controlled by amputation or linear cauterization, but the tubal infection cannot be checked or its sequelae removed without proper attention being paid to the pars interstitialis and the structures immediately surrounding it. Clinical experience has shown that after amputation of the fallopian tubes, the stump which is left in the wall of the uterus may be a source of continued metritis and annoying discharge, or may remain the site of focal infection and cause an exudate and intestinal adhesions. Again, the stump of an amputated tube may become the seat of a tubal pregnancy, for unless the cornu is excised, the lumen of the interstitial portions may remain patent. This assertion is not theoretical, as I have seen three ectopic pregnancies in this location.

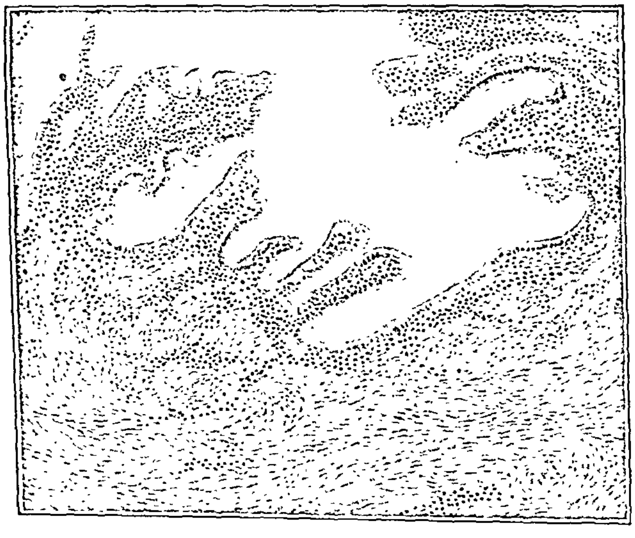

Fig. 3.—Isthmic portion of tube showing round cell infiltration at a distance from the reaction zone.

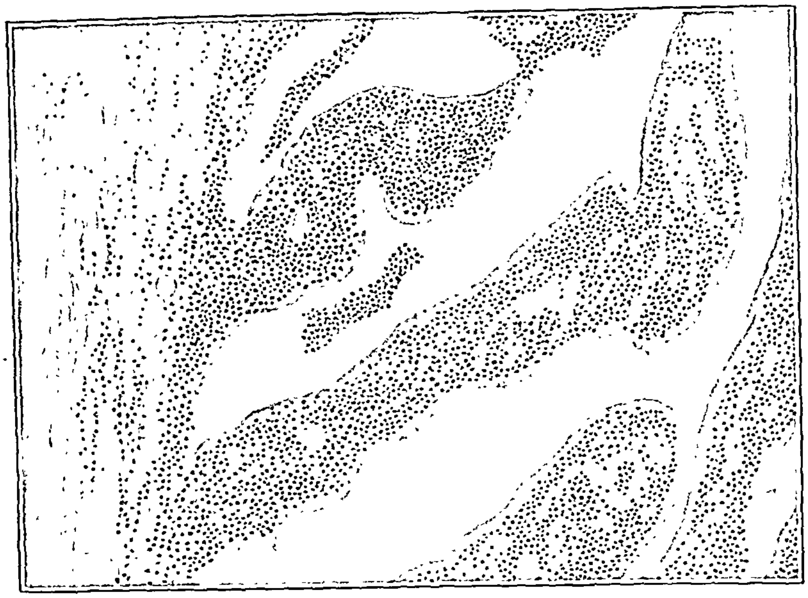

Fig. 4.—Midportion of tube showing inflammatory reaction with round cell infiltration.

In gonorrheal infection, notwithstanding the fact that the gonococcus is primarily a surface organism, it quickly spreads to the deeper layers of the tube, and the gonococci and their toxins may escape not only through the abdominal ostia, but actually through the walls of the oviducts, and excite a local resistance in the form of a plastic exudate at these points. Ordinarily, however, the inflammatory exudate forms within the tube and escapes from the abdominal end into the peritoneal cavity and causes a perioophoritis or an adhesive peritonitis, or the abdominal ostia of the tubes may become closed and the contents be confined within the tube, distending it, resulting in a sactosalpinx, which leaks from time to time into the uterus or abdominal cavity, setting up an exacerbation of the peritoneal inflammation. Both tubal appendages are generally involved, though the infection of the one may antedate the infection of the other. Unilateral salpingitis of gonococcic origin is practically unknown. The disease involves the entire tube. Why, symptoms, by abdominal incision, through which adhesions are separated and the peritoneal cavity protected from the spread of infection by gauze packing; the tube from whose abdominal end seropurulent fluid is flowing is seized and wrapped with a pad of gauze and forcibly milked, squeezing out the purulent fluid and exudation, and in several cases I have seen uncomplicated convalescence follow with regularity of menstruation and hope of procreation.

Dr. Bertha Van Hoosen, Chicago: I think it is important that young women should have the menstrual period preserved, and by leaving the circulation so that the menstrual period is preserved it does much to give the woman speedy relief from the infection. My operation is much like Dr. Polak's. The first step is practically the same. The next step is to put the angiotribe on the uterus. It is practically impossible to include the muscularis in closing the angiotribe, but the peritoneum will be drawn by it over to the side and the uterine muscularis will be pushed toward the middle line. In this way the ureter is pushed to one side; another angiotribe is put in front so that the ureter is pushed still farther out of the way and a little more peritoneum is included in the grasp of the forceps; the same is done on the other side. The peritoneum is incised from just above the bladder line up to the horn of the uterus, because the peritoneum is very adherent to the body of the uterus. The peritoneum is lifted from the uterus by a simple pull with a tenaculum. When the uterus is entirely separated down to the internal os, a dissecting scissors is slipped in and the mucosa of the cervix and enough of the underlying muscularis to include the glands are cut. In this way none of the arteries is interfered with except the very small vessels. The parts are then closed, one stitch being put through the cervical portion anteroposteriorly. The clamp is taken off the part nearest to the middle, and with a silk suture union is made to the fundus. In none of my cases has there been a death.

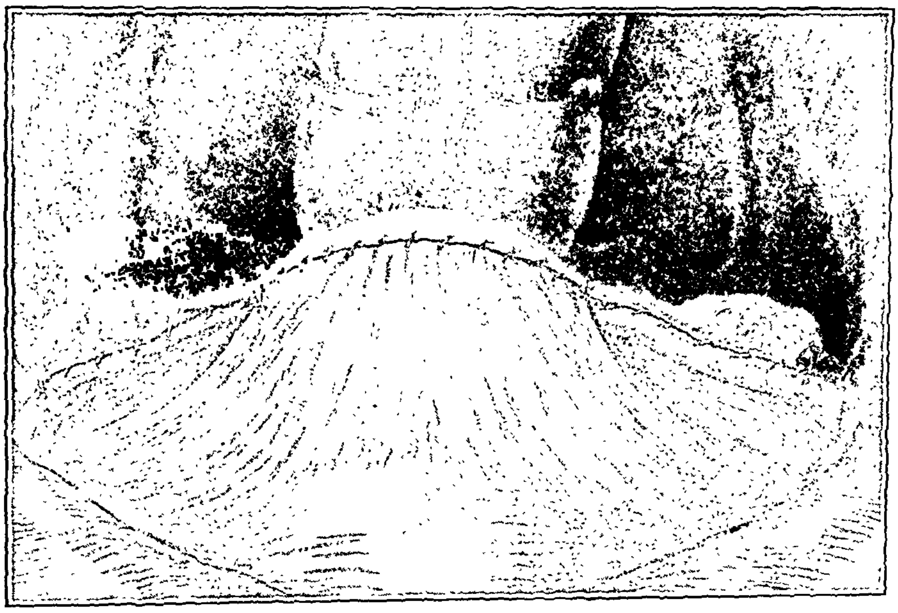

Fig. 9.—Fundal wound peritonealized by reflecting the peritoneum of bladder over it.

Dr. H. J. Boldt, New York: Dr. Polak's words are a verification of the stand which I took many years ago. With regard to further conception, I cannot say that I have had the same experience that Dr. Montgomery has had, since I have not seen any of my patients conceive subsequent to surgical intervention of that kind.

Dr. Harvey P. Jack, Hornell, N. Y.: At our New York State meeting in Utica I detailed an operation looking to preservation of the childbearing function in these cases. It will not always, perhaps not often, succeed, but it is worth trying on its results, even at the slight risk of being compelled to operate again. After I had read my paper at Utica several men came to me and reported successful results as to childbearing as a consequence of conservative work on the tubes. Some of these patients are known to recover and regain the childbearing function without any surgery, so that I think it is time we halted in our efforts, in many of these cases, to do ideal surgery and try to do practical surgery.

Dr. R. H. C. Gibbons, New York: I have never taken stock in these "conservative" operations, although I have done many of them. Many patients who have had "conservative operations"—tube, ovary and appendix removed—have not recovered their health. When the uterus is badly infected it should be taken out in greater part; also the appendages.

Dr. Henry O. Marcy, Boston: This subject has fluctuated back and forth through the years. We should place more emphasis on the conditions for which we operate. It is the character of the infection one should think of quite as much as the location. If the tubes are in the condition referred to by the author of the paper, it is unwise to preserve them. On the other hand, it is wise to be conservative in that one is dealing with that which is important, not to the individual alone, but to the race.

Dr. John Osborn Polak, Brooklyn: I wish to disclaim any originality for the conception of this operation, as the principles involved were conceived and published by Blair Bell of Liverpool and Beuttner of Geneva. Only the perfected technic regarding the circulation of the ovary has been developed by me. With regard to the remarks of Drs. Montgomery and Jack, their discussion is irrelevant, as they are speaking of another class of cases, cases which we all know time will regenerate and in which function will be reestablished. Before describing this operation I showed two slides on the screen which even my friend Dr. Jack must admit are beyond conservation. This operation is only advocated in the class of cases in which the ordinary operator does a double salpingectomy with panhysterectomy, conserving one or both ovaries, with an interfered-with circulation for their internal secretion. Our follow-up work has shown us that the retained ovary after hysterectomy becomes cystic, the seat of adhesions, and that its life history regarding internal secretion is very limited, because its efferent circulation is interfered with.

Two classes of cases have been discussed, one in which the patient will in time get well without operation or at most with the formation of adhesions; the other in which the pathology is so great that nothing short of ablation of the diseased structures will effect a cure. It is in these that I am striving to save the menstrual function as well as the ovarian secretion.

Child Labor Day.—It has been customary each year to designate the fourth Saturday, Sunday and Monday for observance as child labor days in the churches, synagogues, schools and clubs of the country. For 1918 the days designated by the National Child Labor Committee are January 26, 27 and 28. The observance of these dates as Child Labor Days has been approved by Secretary of War Baker, Commissioner Claxton of the United States Bureau of Education, Miss Julia C. Lathrop of the Children's Bureau and Owen R. Lovejoy, general secretary of the National Child Labor Committee, and the officials of many other organizations. To furnish material for programs the National Child Labor Committee is distributing pamphlets dealing with the war situation and with child labor and educational problems in general. Secretary Baker, in endorsing the plans for the observance of the days, said: "The ravages of hostilities bear heavily indeed on the present generation, but we must not permit the effects of it to be visited on the children of the nation. The tribulations borne by the present should make us conserve to as great a degree as possible the health and energies of the coming generations."

CHOLECYSTECTOMY WITHOUT DRAINAGE *

A. MURAT WILLIS, M.D.
Fellow of the American College of Surgeons; Professor of Clinical and Operative Surgery, Medical College of Virginia
RICHMOND, VA.

At this time gallbladder surgery is occupying the attention of surgeons perhaps more than any other subject. The reason for its prominence is obvious. Cholecystostomy, once the operation of choice, has been denounced by an able coterie of surgeons as giving permanent results in not more than half of the cases; and cholecystectomy, a supposedly more dangerous operation, is being substituted for it whenever conditions allow.

All are familiar with the condition found at operation after a previous cholecystostomy. Often the liver is turned up at its lower border and lies on a level with or above the costal margin, having diaphragmatic and peritoneal adhesions. The duodenum, transverse colon and stomach are often adherent to the gallbladder and the liver. I believe this is due entirely to the drainage, which does not allow the liver to assume its normal position, and which, in my opinion, is responsible for the adhesions to the other structures. In every case in which I have done a cholecystostomy and later gone back into the abdominal cavity, I have found a mass of adhesions about the gallbladder. In fact, I have never seen, in secondary operations elsewhere in the abdomen, the same number and density of adhesions. I have never found a case which did not have this condition. It is impossible for me to state from my operative observation how many adhesions form about the gallbladder region after a cholecystectomy without drainage, as I have never had occasion to reopen the abdomen in such cases. I feel confident that fewer adhesions would be found associated with a more normal condition of this region. I am sure, however, that this result will be obtained only with careful removal, allowing no bile to escape into the cavity.

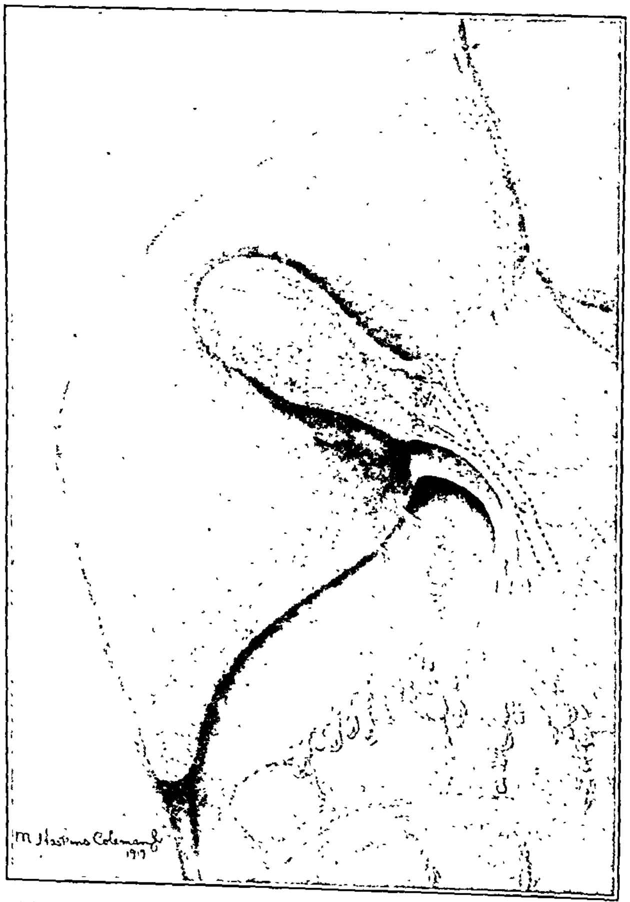

Fig. 1.—Relations of cystic duct to common duct. Dotted lines indicate direction of incision in hepatoduodenal ligament.

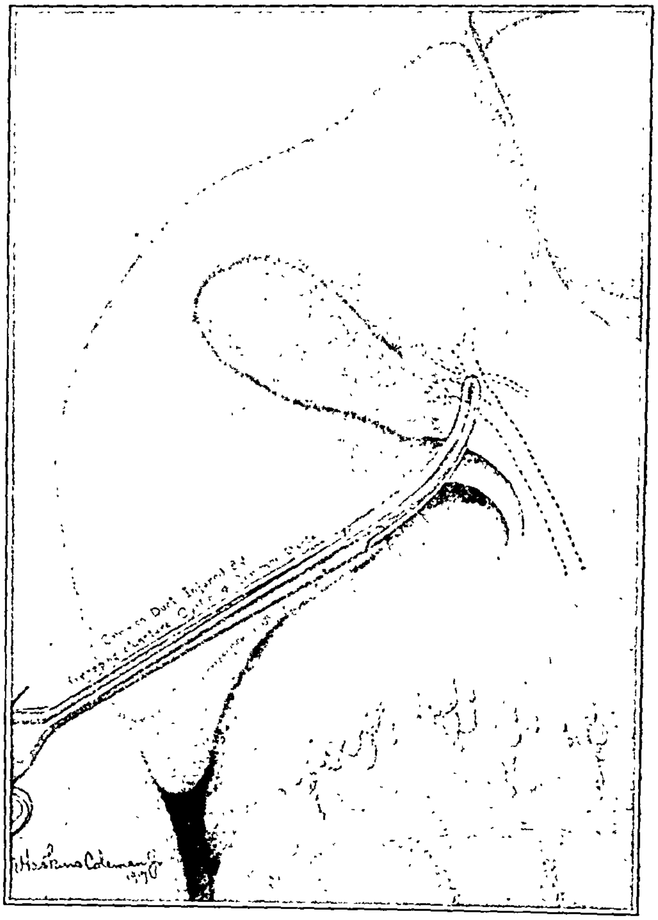

Fig. 2.—Method generally employed. When making sure of the cystic duct, the curved artery clamp is apt to grasp and injure the common duct as well.

In some recent experiments by Dr. Budd and myself, we were able to demonstrate that presumably healthy bile, if spilled in the region of the gallbladder, would produce a moderate amount of adhesions, and that bile infected with the colon and typhoid bacillus would produce extensive adhesions. We were also able to show that infected bile spilled in the region of the gallbladder, plus drainage, were followed by even more extensive adhesions. We removed gallbladders without liberating bile in the cavity, closing without drainage, and in these cases the number of adhesions was negligible.

About five years ago, we were first impressed with the number of cases of cholecystectomy which never leaked any bile through the drain after operation. We began, in carefully selected cases, to close without drainage, and found that excellent results followed. We began to enlarge more and more on this group,

---

* Read before the Maryland Medical and Chirurgical Society, Baltimore, April 25, 1917.

until now we remove quite a large percentage of gallbladders without drainage. We do not believe that all cases can be closed without a drain, but do contend that a big percentage can be done in this way, provided, of course, the surgeon is careful to spill no bile in the cavity and to leave no bleeding surfaces.

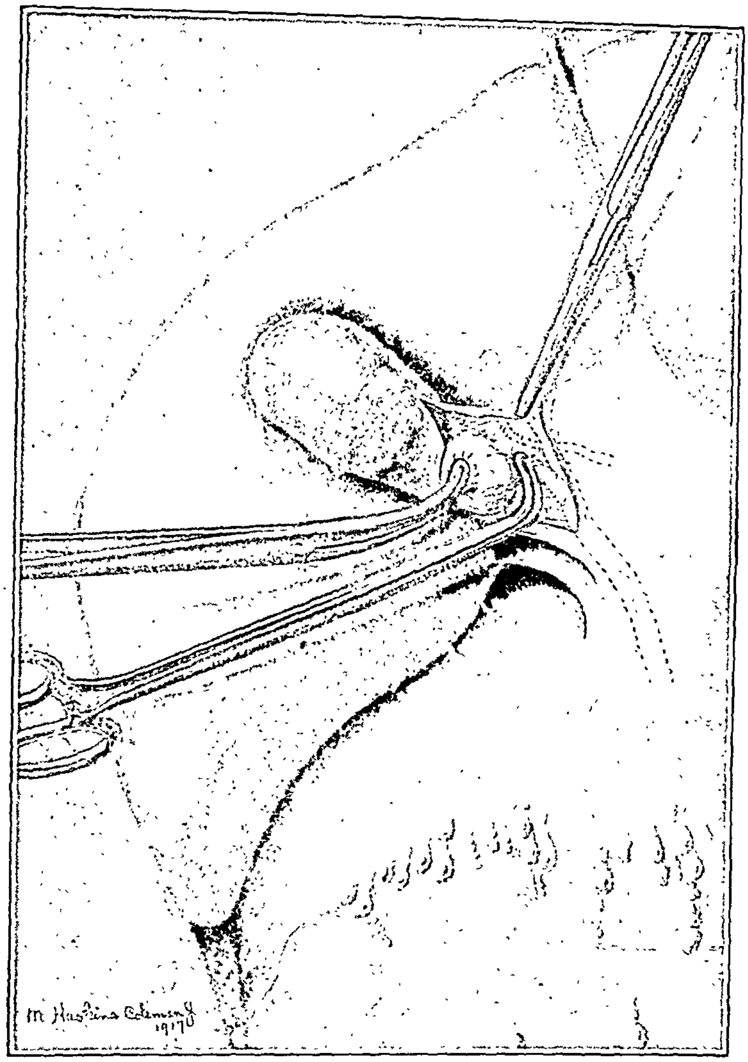

Fig. 3.—Incision made in hepatoduodenal ligament. Pouch of gallbladder rotated up, and right angle clamp placed on cystic duct and artery.

We believe that the technic of the removal of the gallbladder, whether from the fundus down or from below upward, is largely a matter of each surgeon's preference as to the method by which he can best control the situation. I myself believe that the removal from below toward the fundus offers the greatest advantages.

OPERATIVE TECHNIC

Using the right rectus incision curving at the upper end toward the xiphoid, we bring the gallbladder at once into view. Rotating the liver upward, we make an incision in the hepatoduodenal ligament, as shown by the dotted line in Figure 1, and by blunt dissection bring the cystic duct into the field.

The method generally employed is to place a curved clamp over this ligament, as shown in Figure 2. We believe that this in itself is responsible for many reported injuries to the common duct in cholecystectomy, as the clamp, in being placed sufficiently far to assure the grasping of cystic duct and artery, is liable to grip the common duct as well. There is also a possibility of a ligature being put through or around the common duct when the cystic duct is tied off, or of the scissors injuring it when the cystic duct is cut. It is to be borne in mind that the cystic duct does not join the common duct at right angles in a great many instances, but runs parallel to it and right alongside.

We believe that this accident is obviated absolutely in our method. Grasping the pelvis of the gallbladder and pulling upward, we are able to apply a right angle clamp on the cystic duct and artery, as shown in Figure 3. Figure 4 illustrates what we have found to be the usual relations of the cystic duct to the pelvis of the gallbladder, certainly in pathologic conditions. Then, a No. 2 catgut ligature is placed around the cystic duct close up to the junction with the common duct, and we are careful to cause no stricture of the latter. We thus avoid leaving sufficient cystic duct to form a bud in which future trouble is liable to occur. Another ligature is now placed around the cystic duct and artery, and the two are cut (Fig. 5). By blunt dissection with the back of the knife and the finger, the gallbladder is dissected back to the fundus, care being taken to leave the peritoneal coat of the liver intact. The gallbladder is removed, sufficient peritoneum being allowed to remain to close the space without tension. A crown suture is placed through the peritoneum and under the stump of the cystic duct, being brought back over the stump and tied, as shown in Figure 6. This drops the stump back in the liga-

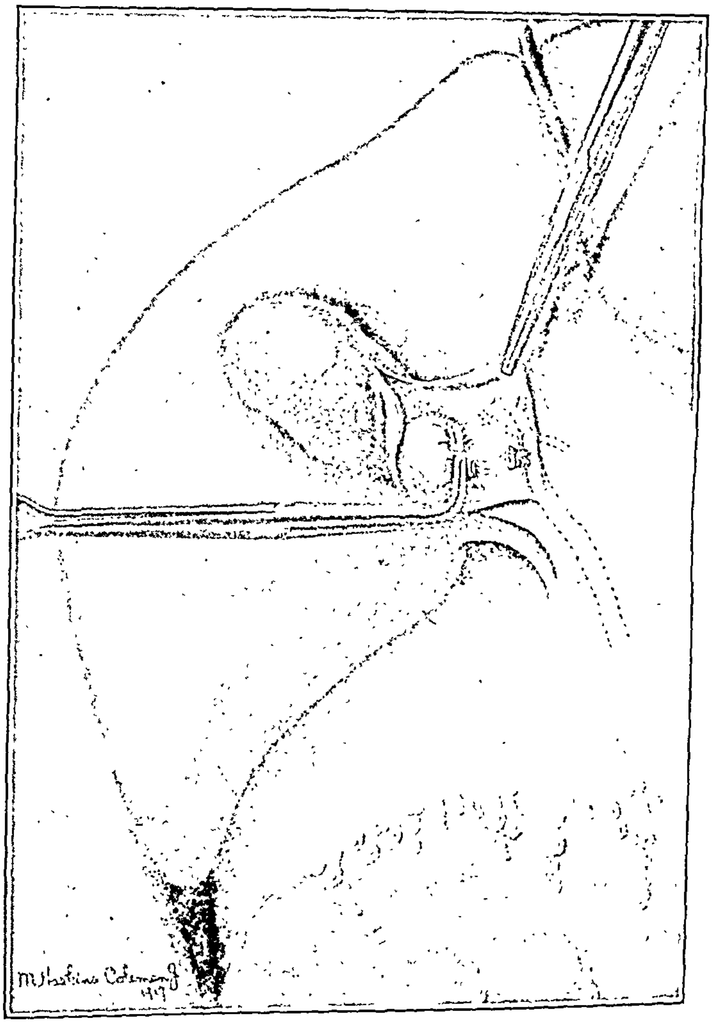

Fig. 5.—Ligature placed around cystic duct, also around cystic duct and artery close to common duct, and cut.

ment, and a continuous suture closes all raw surfaces and leaves a clean field, as shown in Figure 7. We then close without drainage, and have no fear that bile will escape into the peritoneal cavity.

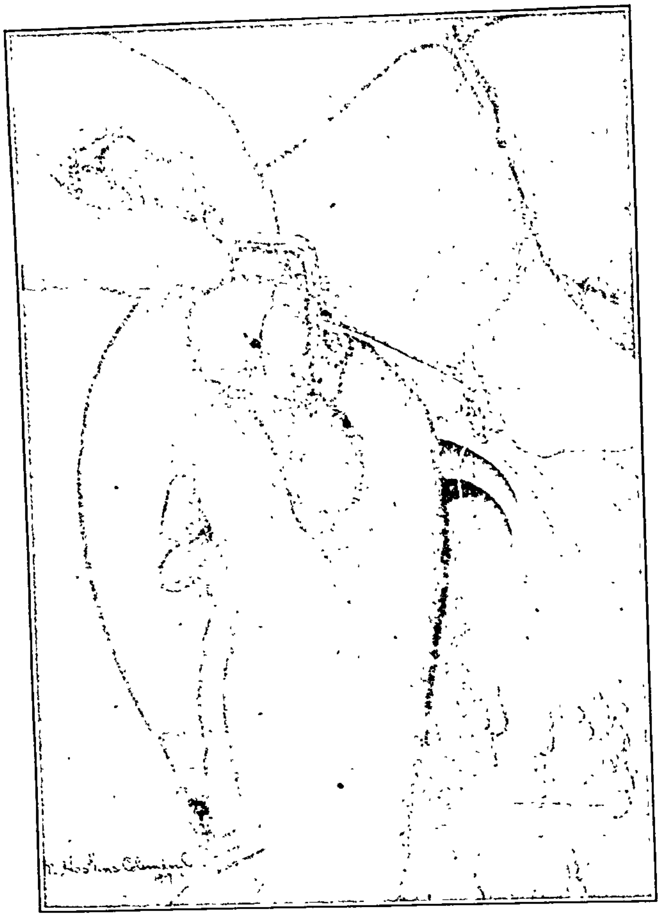

Fig. 6.—Crown suture in place under and over cystic stump. Gallbladder being dissected back to fundus.

RESULTS OF OPERATIONS

Our experience in surgery of the gallbladder is based on 549 operations for cholelithiasis and cholecystitis with twelve deaths, or 2.2 per cent. In this series, 466 patients, or 86 per cent., had gallstones in the bladder or duct; eighty-two patients, or 14 per cent., had no gallstones, but showed various stages of cholecystitis. There were 398 cholecystostomies with seven deaths, or 1.7 per cent., and 107 cholecystectomies with one death, or 0.9 per cent. In thirty-eight of our cholecystectomies, we left no drainage. It was in this group that the one death occurred. There were forty-four choledochotomies with four deaths, practically 9 per cent.

There were twenty-six secondary operations. Twenty-one followed the operation of cholecystostomy and five occurred after choledochotomy. Gallstones were found in twelve of the secondary operations; seven in the cholecystostomy and in all five of the choledochotomy group.

This series presents several interesting facts. The women outnumbered the men five to one. The percentage of deaths in the common duct cases was about five times as great as the mortality in other gallbladder work. The causes of death in the common duct group were secondary hemorrhage and infection. The mortality in our cholecystectomies is much lower than in the cholecystostomies. This is due to the fact that cholecystectomy on the whole was performed in the more favorable type of case.

The patient lost in our cholecystectomy group was a woman aged 66 with a simple case of cholelithiasis. The gallbladder was ruptured during removal. Drainage was not used, as we were able to cover the raw surface and clean out the peritoneal cavity. She had urinary suppression, and died three days after operation. At necropsy a small abscess was found between the liver and transverse colon, and an acute nephritis was revealed. There was no evidence of the escape of bile. It is impossible to say whether she died from acute nephritis or an infection; but in future, under similar circumstances, we shall drain.

It should be borne in mind that this mortality represents the patients who have died in the hospital after operation on the gallbladder. Some of these patients undoubtedly died of causes other than those which can be attributed to the immediate effect of the operation, but, because of the fact that they died in the hospital, we have included them in the gallbladder mortality.

CONCLUSIONS

1. Cholecystectomy for simple infections of the gallbladder is a most successful operation, especially if this can be done without soiling the peritoneum by the contents of the gallbladder, and closing without drainage. 2. Adhesions of organs which normally have a certain amount of mobility cause postoperative complaints, especially in the gallbladder region, and we feel that any operation which will limit these is certainly a step in the right direction.

PIGMENTATION OF THE HIND-GUT

A PATHOLOGIC AND EXPERIMENTAL STUDY *

W. LANDRAM McFARLAND, M.D.
Clinical Professor of Bacteriology and Pathology, Polyclinic Hospital
NEW YORK

The presentation of a paper based on the observation of a small number of cases must justify itself by dealing with a rare condition or by demonstrating new facts concerning a well known subject. With the advance of intestinal surgery, and the increasing number of "developmental reconstructions" and other operations which involve removal of the cecum and part or all of the first portion of the hind-gut, we are able to note with more frequency a pigmentation or melanosis of the mucosa of both organs. This pigmentation may or may not be transitory; but the rarity of its observation at the necropsy table, and the fact that at times a fading of color may be noted through the proctoscope, lead to the supposition that, in not all cases at least, is it macroscopically permanent.

PATHOLOGY

Gross Pathology.—Both the gross pathology and the histopathology of pigmentation of the hind-gut have been so clearly given by Pick that any subsequent description of the tissue changes observed must of necessity follow him closely in detail if not in phraseology. Macroscopic appearance of the intestinal mucosa in pigmentation of the hind-gut not only varies with the amount of pigment present, but is evidently influenced to a certain extent by the manner in which the tissue is handled. In tissue removed at operation, the color is materially affected by congestion which follows clamping, and in three cases here cited pigmentation was revealed only by microscopic examination. This factor may to some extent be responsible for the infrequent recognition of pigmentation of the hind-gut at time of operation and divert such tissue from the laboratory to the furnace of the unscientific hospital. In such portions of the hind-gut as may be observed by means of the proctoscope, the color varies from gray-black to light brown, or it may have the mottled "toad's back" appearance mentioned by Pick. Two specimens of the present series which were removed at operation and included the ileocecal valve, cecum and ascending colon were uniform gray-black or mottled throughout. Pick has described the mucous membrane as being mottled like a toad's back, and noted the following variations in color: "The tint may become a little lighter in diffuse spots of the mucosa, or in an entire segment, passing from a deep black into a lighter shade of brown." He further notes that there may or may not be a failing of melanosis toward the rectum. On these minor points my observations are not entirely in accord with those of Pick. In the one case seen at necropsy there was an even tar-black pigmentation from ileocecal valve to rectum; in the other cases, even shading throughout the specimen. It is natural that the influence of postmortem change should be thought of, but the specimen of this series was secured within two hours after death, and it is not probable that such a factor would be overlooked by Berlin's most astute pathologist. A cut section of the intestinal wall may show a thin brown or black line corresponding to the mucosa, or the surface may exhibit nothing indicative of pigmentation. There is variation in thickness from that of tissue paper to somewhat more than normal. Extreme thinness is confined to the cecum and is, of course, a condition frequently noted in long standing cases of intestinal stasis. The serosa shows no change. In Case A, the mesenteric glands of the mesocolon were darkened. In Case A, the abdominal organs, as in the cases of Pick and other observers, were free from pigment.

Microscopic Pathology.—When the intestinal wall has markedly thinned, there is, of course, a diminution in the depth of the gland pits; otherwise they appear to maintain their normal depth. The cells lining the glands may be somewhat increased in size, they may present a normal appearance, or they may be somewhat smaller than normal. The goblet cells are neither increased or diminished in number, nor do cells foreign to this layer appear. The connective tissue of the mucosa is not affected except in the very thin intestines, where it appears to have undergone some degree of atrophy. In the connective tissue of the mucosa, between the basement membrane of the gland epithelium and the muscularis of the mucosa, are observed a varying number of pigment cells. These cells may be arranged in a uniform layer and lie close to and follow the basement membrane of the epithelium, or scattered through the stroma of the mucosa. The cells vary in size from 7 to 20 microns and have a single round or oval concentric nucleus. Such pigment as they contain is not uniform either in size of granules or in color. Some cells are gorged with large light or dark brown granules, while others hold dust-fine, saffron-colored particles. There is also a certain amount of free pigment in the form of isolated granules or clumps of granules, though the clumps of granules may be pigment cells so overloaded with pigment as to obscure their cell bodies. The pigment cells resemble morphologically the plasma cell found normally in this locality, though Pick considers them connective tissue cells of the tunica propria, and Henschen and Bergstrand regard them as several types of the wandering class of connective tissue cells of the stroma of the mucosa. Sections of two ileocecal valves showed pigment to stop at a midpoint in the valve, the ileac side being pigment free. Large numbers of eosinophils may at times be seen in the mucosa, and in Case A an occasional ameboid-looking body was noted, but the character of these bodies could not be determined. The last tissue examined exhibited pigmentation of the distal end of the ileum.

Submucosa: In several cases pigment cells were found in the solitary lymph nodes, and occasionally a cell can be seen beneath the muscularis, which is in contradistinction to the description of Pick, but has been noted by Henschen and Bergstrand. The muscular walls and serosa were free of pigment cells, and neither I nor my colleague, Dr. Jeffries, could note microscopic change worthy of mention other than occasional atrophy. Mesenteric glands: In Case A, pigment cells corresponding in every way with those of the mucosa could be seen. These cells appeared to be principally gathered on one side of the gland in a position probably corresponding to the junction of the afferent duct.

* Read before the Section on Pathology and Physiology at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

* Because of lack of space, *this article* is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the author's reprints.

Chemical Examination.—It would be of no avail to chronicle in detail a series of failures. All solvents and dyestuffs which I could think of, or which were suggested by the experiments of others, gave negative results. Hence, if deduction can be drawn from negative results, the pigment, from its resistance, must resemble the melanin group.

NATURE OF THE PIGMENT

Pigments relating to intestinal pigmentation fall naturally into two groups—exogenous and endogenous. Of exogenous pigments but little need be said, they being, as a rule, salts of either silver or mercury, easily accounted for in the clinical history of the patient and demonstrated without difficulty by chemical and microchemical methods. Endogenous pigments present a much more difficult problem for consideration, and it is practically impossible to confine such considerations to any specific pigment or group of pigments. Von Gierke[12] says one can divide endogenous pigments into two great groups, those derived from blood pigment (hemoglobin pigments) and those formed from other body substances through cell activity (autogenous pigments). If one follows the classification of Heuck, endogenous pigments encountered in the body may be divided into the hemoglobin pigments and the autochthonous pigments. Further subdivision separates the hemoglobin pigments into three groups, malarial pigment, hematoidin and hemosiderin. The autochthonous pigments include the fat-containing abnutzungspigment and the melanin. In contradistinction to the classification of Heuck, and as illustration of the diversity of opinion on the subject of body pigments, may be quoted the following somewhat broad definition by Adami.[13] In the paragraph dealing with "modified hemoglobin," Adami speaks of a succession of modifications of the hemoglobin pigment "hematin," leading to the eventual deposit in tissue of two, or more correctly, three substances, hematoidin, hemosiderin and hemofuscin. Further, Stengel and Fox[14] say that consideration of hematogenous pigment "concerns the deposition of pigments derived from hemoglobin, of which there are two groups, the siderous and the nonsiderous. The chief siderous pigment is hemosiderin, which has, however, many modifications; the nonsiderous pigments are derivatives of hematin-hematoidin, hemafuscin, melanin, etc." Heuck, on the other hand, does not think that hemosiderin is derived from hematoidin, nor does he consider hemofuscin one of the pigments coming from coloring matter of the blood but rather belonging to that class of pigments originating from lipoid substance and in consequence being an abnutzungspigment identical with the lipofuscin of Borst. As to the derivation of melanin or melanins, von Furth, according to Adami, regards them as being developed by the action of intracellular oxidases (tyrosinase) on the aromatic chromogen group of the protein molecule.

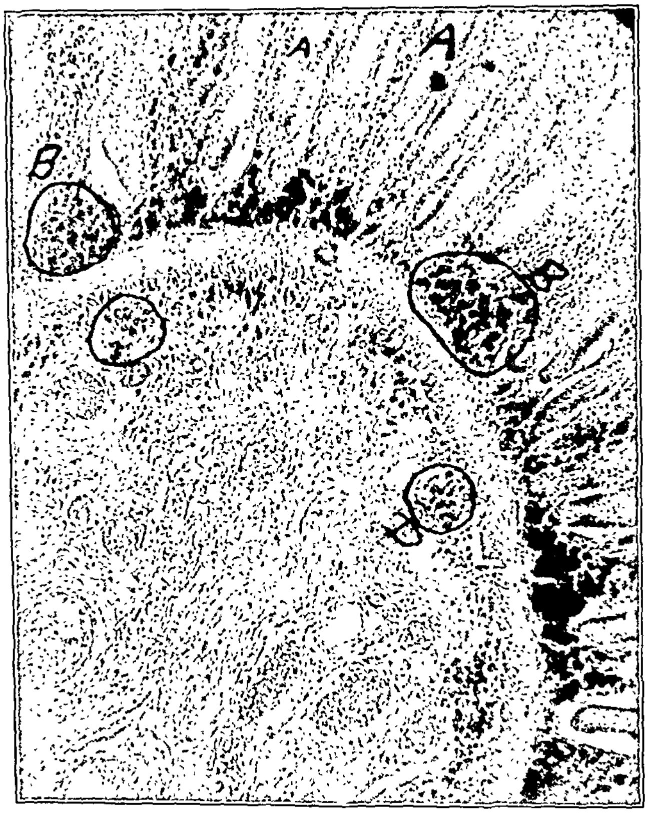

Fig. 1.—Pigmentation of the ileum: *A, A*, gland; *B, B*, pigment cells; *C*, muscularis mucosa; *D*, submucosa; pigment cells in submucosa. (Photograph by Dr. Wightman.)

As it is not necessary here to regard malarial pigment, the chemical composition of only two of the blood pigments need be considered, following the classification of Heuck. Concerning the exact nature of these pigments and the chemical processes involved in their formation there is much controversy. Their characteristics in general, however, are as follows: Hematoidin is a red or brownish gold, crystalline or granular substance, dissolved in concentrated sulphuric and nitric acids and distorted by alkalies; its iron reaction is negative. Hemosiderin is a golden yellow to brown, granular or flaky substance, soluble in acids but insoluble in alkalies; its iron reaction is positive. The definition of abnutzungspigmenten or lipoid pigments given by von Gierke is that by such are understood a class of granular, golden brown pigments that give a lipoid reaction. As illustrations he mentions pigment found in heart muscle, liver, seminal vesicles, etc., which may be normally present or occur in diseased tissue. Heuck describes it as a golden brown, flaky substance insoluble in acids or alkalis; its iron reaction is negative; it is always positive to basic dyes and irregularly positive to fat dyes. Hammersten,[15] in writing of melanins, says that there are some forms which are slightly soluble, and others easily soluble, in alkalis. He mentions choroid pigment as an example of sulphur-free melanin. Others mention melanin as a substance containing a minimal amount of iron but a relatively considerable quantity of sulphur. According to Heuck's table, melanin is a substance occurring in the form of brown crystals or flakes; it is insoluble in acids and alkalis and does not take any stains which are used for the identification of abnutzungspigment.

For the identification of pigments, one must consider the morphologic, michrochemical and staining tion of Heuck that we are merely observing an increase of a normally present pigment. From the position of the vast majority of pigment cells it would appear that the ferment acts with rapidity on the first intercellular substance which it encounters after passing the basement membrane. In support of this theory it must be remembered that in the mucosa of the cecum and hind-gut we are not dealing with as highly specialized tissue as that of the liver or of the kidney, but with a tissue whose even passive function has been considered by some as anatomically and physiologically nonessential. As the cecal and colonic mucosas are practically passive walls through which fluids pass, it is more probable that the action of the pigment-producing ferment is on intercellular substances and fluids and not on intracellular substance of any cell or group of cells. The variation in pigment building capacity mentioned by Pick should depend more on duration and intensity of stasis than on difference of individual property to produce pigment-forming enzyme. This is supported by the statements of Henschen and Bergstrand regarding the number of pigmented intestines they encountered in individuals past 40, and by my experience with intestines removed because of chronic intestinal stasis.

Pigment cells are, in my opinion, plasma cells which have acquired visible phagocytic properties. These cells are found in considerable numbers in the stroma of the mucosa; and the cells studied appeared to be morphogically nearer the plasma cell than any other found in the locality. By arrangement of the pigment-containing cells, it would appear that the plasma cells attempt to follow the action of the white cells, which become phagocytes, and to form a protecting wall against further invasion by pigment-producing enzyme, in addition to removing the pigment. Were it possible to follow microscopically the change accompanying permanent acceleration of the fecal current, one could no doubt observe, coincident with decrease of pigment-forming enzymes, a gradual assimilation of pigment granules, as suggested by the experience of Lynch. Migratory properties of the plasma cell carry it to different parts of the connective tissue stroma, and at times to and beyond the muscularis. Those pigment cells seen in the solitary follicles and in lymph nodes of the mesocolon may be accounted for by the migratory properties of the cell or by the effort of the lymphatic system at removal of waste products.

The theory of Lynch is so at variance with that of other writers that it must be considered apart. It should be of material interest to the reader because of the unusual opportunity for the clinical observation on which it is partially based. I, however, cannot consistently reconcile Lynch's idea of the effect of bacterial infection with the number of nonpigmented but severely infected hind-guts which I have had the privilege of examining for him. Furthermore, it is difficult to understand why a selective action for intestinal pigments should be conferred almost uniformly on cells of the connective tissue stroma of the hind-gut.

REPORT OF CASES

SERVICE OF DR. LYNCH

Case 1.—Mrs. M., aged 45, had had obstipation for ten years. An operation for developmental reconstruction was performed. Tissue examination revealed pigmentation confined to the mucosa of the hind-gut. The solitary nodules were pigment free. There was no change in other intestinal walls.

Case 2.—Mrs. O., aged 50, exhibited symptoms which Dr. Lynch associates with pigmentation of the hind-gut. There was prolonged constipation, toxemia, urine at times free from indican, and blood in the stools. Proctoscopic examination revealed ocher-colored pigment extending from the anus to the sigmoid. Tissue examination of bit snipped through the proctoscope revealed pigmentation of the mucosa. The appendix exhibited pigmentation of the mucosa.

SERVICE OF DR. DRAPER

Case 3.—Mrs. R., aged 44, had severe hemicrania averaging fifty a year, together with severe congenital constipation. An operation for developmental reconstruction was performed. Tissue examination revealed pigmentation confined to the mucosa. The lymph nodes were free. There was pigmentation of the cecal half of the iliac valve. There was no change in the muscle walls.

Case 4.—Mrs. B., aged 34, had mild mental obsessions and marked depression, with severe congenital constipation. An operation for developmental reconstruction was performed. Tissue examination revealed no pigmentation of the ileum. The cecal half of the ileocecal valve was pigmented. There was pigmentation of the mucosa of the cecum and the hind-gut. Solitary follicles were pigment free. There was no change in the muscle walls. The lymph nodes of the mesocolon were pigment free.

Case 5.—Mrs. R., aged 55, had chronic constipation for twenty years. An operation for developmental reconstruction was performed. Tissue examination revealed pigmentation of the mucosa only. There was no change in the muscle walls.

Case 6.—Mr. A., aged 60, had profound toxemia. Obstipation had existed for twenty years. An operation for developmental reconstruction was performed. Tissue examination revealed pigmentation of the terminal portion of the ileum and the entire hind-gut. Pigment involved the solitary follicles as well as the mucosa, extended into the submucosa, and was to be found in the lymph nodes of the mesocolon. There was marked atrophy of the muscle walls.

SERVICE OF DR. BAINBRIDGE

Case 7.—Mr. M., aged 36, was always constipated. Colectomy was performed. Tissue examination revealed the ileum pigment free. Pigment was confined to the mucosa of the cecum and hind-gut. There was some atrophy of the muscle walls. As an interesting side light on the toxicity of cecal contents in these cases a cubic centimeter of such, from this case, was injected into the peritoneal cavity of a 250 gm. guinea-pig and caused his death in two hours, the symptoms being those of profound toxemia.

SERVICE OF DR. MEEKER

Case 8.—Mrs. W., aged 42, was troubled with prolonged constipation, etc. Colectomy was performed. Tissue examination revealed profuse pigmentation of the mucosa of the terminal portion of the ileum; also pigment in the solitary follicles and the submucosa.

Three other pigmented intestines are not mentioned in this group because of insufficient clinical data. Of the twelve intestines examined after operation for chronic intestinal stasis, eleven were pigmented. Not including appendixes, we have examined 206 intestinal tissues in our laboratory in the past five years. The foregoing eleven were the only pigmented ones which came to our notice.

COMMENT

It would appear that pigmentation of the hind-gut is a condition dependent on chronic intestinal stasis rather than incident to it. That it is a result, and not a primary contributing cause of obstipation, is indicated by consideration of clinical data in conjunction with histologic findings in tissue obtained both at necropsy and from the operating table. The influence of pigment, after formation, on the normal physiologic function of the hind-gut is, as are most phases of this problem, a matter on which one is compelled to theorize because of inability to establish facts. Physiology of the hind-gut does not brilliantly illumine the pages of standard textbooks. Other than that the hind-gut serves as a connecting link between the small intestine and rectum and that it absorbs to a certain extent, and secretes a watery enzyme-free fluid, there is but little information pertaining to its functions. That both absorptive and secretory functions should bear directly on the degree of obstipation is understood when one takes into consideration their influence on consistency of fecal mass, lubrication of the intestinal mucosa, and effect on bacterial action. It is, of course, impossible to more than conjecture how materially normal functions of the mucosa are retarded by the presence of pigment. A study, however, of the position of many of the pigment cells would indicate that their interference must be a considerable one. So characteristic was the position of the majority of the cells to Solger, that, noting how they followed the peripheral line of vessels, he attributed pigmentation to circulatory disturbances.

If one recalls for a moment the normal histology of the mucosa of the cecum and hind-gut, he will remember that it is roughly as follows: (*a*) a single layer of columnar epithelial cells resting on a basement membrane; (*b*) connective tissue stroma containing central arteries, veins, lymphatic stem and nerves, with fine branches spreading from the central vessels and anastomosing directly beneath the basement membrane; (*c*) muscularis mucosa composed of a thin layer of muscle fibers separating the mucosa from the submucosa. With this histologic picture in mind, it must be conceded that a foreign substance in greater or less abundance when interposed between anastomosing branches of terminal blood vessels and between or in lymph spaces, mechanically at least, interferes with the normal performance of the functions of these parts.

If secretions are diminished there is a coincident loss of moisture to the fecal mass and defective lubrication of the mucous membrane. This has been graphically described by Lynch in his protoscopic picture of a dry mucous membrane covered with sticky fecal masses. If absorption is retarded, fats which would otherwise pass through the intestinal wall remain within the cavity and both promote and accelerate bacterial decomposition. On the other hand, however, with retarded absorption, there would be less fluid withdrawn from the fecal mass, though this might be a feature of small importance, owing to the turbidity of the fecal current and the consequent extended period during which absorption can take place.

In both the pigmented and nonpigmented cecum and adjacent hind-gut, during chronic intestinal stasis, there appears first to occur a congestion and edema of the mucosa, accompanied by congestion manifest in all blood vessels throughout the several intestinal walls. Following this phase, if the condition persists, there occurs a very slow but progressive atrophy not only of the mucosa but of all walls of the intestine. (By this I do not wish to convey the impression that atrophy continues until fibrous tissue ultimately replaces the normal structures. In no tissue which I have studied was there an absence of any of the normal coats of the intestinal wall, even though they had been extensively thinned out.) Not considering senile atrophy, we may presume these changes to be due, first, to an irritation of the mucosa which may be either chemical or mechanical and is probably both. After the preliminary irritation, there begins a gradual overdistention followed by loss of tonicity through constant stretching, and disturbance of circulation from pressure of gut content and compression by gut walls. It is more logical to attribute such changes to the causes mentioned than to suppose them to be due to the presence of pigment in the mucosa, though the possibility of a toxic element derived from pigment is within the bounds of speculation.

CONCLUSIONS

If the foregoing premises are correct, it is possible to draw the following conclusions:

1. In true melanosis of the hind-gut, the pigment is not derived from blood pigment, but is a substance between true melanin and fat pigment.
2. This pigment is probably formed by an enzyme which, manufactured by the intestinal contents, acts on the intercellular substance of the stroma of the intestinal mucosa.
3. Pigment-containing cells are derived from plasma cells of the stroma of the intestinal mucosa.
4. Intestinal pigment is primarily an accompaniment and not a cause of chronic obstipation.
5. The clinical significance of intestinal pigmentation concerns the duration and intensity of obstipation, and, while a contributing influence in established obstipation, is not an initial etiologic factor.

ABSTRACT OF DISCUSSION

Dr. R. A. Lambert, New York: By what method of examination did Dr. Lynch note the disappearance of the pigment in the three cases which he studied?

Dr. Alfred F. Hess, New York: Does the pigmentation occur in children, or only in adults?

Dr. James Ewing, New York: I have encountered pigmentation of the large intestine somewhat frequently and I think that small amounts of this condition are not so uncommon as Dr. McFarland's references to the literature would indicate. I recall one rather pronounced case in a physician who suffered from chronic anemia and long continued obstipation. The entire large intestine was dark brown. He also suffered from a peculiar degeneration of the voluntary muscle system and of the peripheral nervous system, the exact designation of which puzzled our New York neurologists. We interpreted the intestinal condition as the result of the chronic intestinal obstipation and intoxication.

Dr. John W. Draper, New York: I had the pleasure, in connection with Dr. Lynch, of furnishing a part of the tissues from which these studies were made. I know nothing of the origin of the pigment excepting what I have learned from the study of Dr. McFarland's paper. We have observed clinically one important matter—the improvement in the cases operated on has in a general way been proportionate to the amount of pigment present. It may be, therefore, that the presence of the pigment, which in most cases was easily discoverable when the abdomen was opened, may be an index of value for the operating surgeon.

Dr. Jerome M. Lynch, New York: I have been studying this question for five years and am sorry that I can throw but little light on the origin of bowel pigmentation. I have seen a comparatively large number of patients. They are all very toxic, constipated, bleed from the bowel occasionally and have severe periodic headaches. The toxicity is relieved if the bowels are kept open, and the pigment gradually disappears if irrigations are continued over a long period. The pigment varies from an ochre to a black shade and is sometimes divided into rectangular blocks. It is an interesting problem, and I hope that this paper may lead to further study and information on this important subject.

Dr. W. Landrum McFarland, New York: The observations of Dr. Lynch in regard to the disappearance of the pigment were made with the proctoscope. He saw the discolorization of the intestine—the usual picture before the treatment, and the disappearance as the patients were treated—just as you would the fading out of anything that is decolorized. Of course his observations were macroscopic. The youngest case that I have seen on record was that of a person 16 years of age. The worst pigmentations were in persons over 40. The remarks of Dr. Ewing were interesting. The Germans think the condition rare; the Swedes do not. Eight out of the eleven intestines that were sent to me have shown pigmentation, so I do not consider it a rare condition.

WHEN IS CANCER OPERABLE?*

J. WALTER VAUGHAN, M.D.
DETROIT

During the past ten years, my assistants and I have experimented with many various substances in the hope of throwing some light on a better understanding of the cancer problem.

The work[1] first reported contained a brief case report on the use of vaccines prepared from cancer protein, and later publications[2] gave reports of various scientific findings as they were encountered during the progress of this study.

Other workers, notably Blumenthal[3] and Lünchenbein,[4] have reported clinical observations which corresponded to those that I had previously reported. From a scientific standpoint, the work of Gruner[5] agrees with changes I have observed chiefly in advanced malignancy, while of decided corroborative value is the research of Murphy,[6] showing the effect of spleen destruction on the transplantability of tumors.

Indeed, the literature on the subject of malignancy abounds with isolated observations made by many independent investigators which, when taken collectively, all point toward the verification of the conclusions reached by me from my own investigations.

While these investigations have not added much of decided value to the solution of the cancer problem from the standpoint of ultimate control of the disease, yet they have contributed much toward what I might term its intelligent treatment, and they have given us an exact knowledge as to when operative treatment is indicated, as well as to when such treatment will shorten life rather than prolong it.

Obviously it would occupy too much time to give in detail the mass of experimental work that has been done before the facts, on which the following conclusions are based, were elicited. However, these have all been published before, and the references to such publications are appended, so I will occupy the time by a simple statement of the facts, together with a brief report of the conclusions that must be deduced from them.

Metchnikoff, in his classical work on phagocytosis, was the first to show that tissue cells when introduced into the animal body were ingested by the type of large mononuclear leukocyte that is formed in the spleen. At this time, owing to the importance of his observations on the rôle of the polymorphonuclear leukocyte in bacterial infections, but little attention was paid to his observations on the large mononuclear cell, and he himself never associated this cell with any protective function in malignancy.

The next work calling attention to this endothelial blood cell of splenic origin, and the first associating it with the protective apparatus against malignancy, was that performed by my assistants and myself.[7] Altogether we have done over 30,000 differential blood counts and have ascertained that there is invariably an increase in large mononuclear leukocytes following the injection of cancer protein into normal persons or animals.

The percentage of increase is dependent on certain factors, chief among which is the number of body cells with which the protein comes into contact.

Thus a subcutaneous injection is followed by a slight increase, an intravenous injection by a greater increase, and the intraperitoneal method gives a still greater increase.

Another important factor is that the sensitizing dose should not be too large—from 5 to 10 minims of a 0.5 to 1 per cent. solution or suspension of either residue or vaccine is sufficient.

This increase in percentage of large lymphocytes is of short duration, lasting from about four to twenty-four hours. During this time the animal is sensitized to large intravenous doses of the protein; but such sensitization is lost when the increase in large mononuclear cells again recedes.

At the time these observations were first made, I was working under the mistaken impression that this reaction was specific for cancer tissue; but the work of Fischera[8] helped to show this to be untrue.

Fischera was experimenting with fetal autolysate in the treatment of malignancy, and had reported decided clinical benefit in some cases. I immediately started blood counts following injections of fetal autolysate, placental residue, and tissue vaccines from every source, and obtained results of decided interest.

Chief among these was the fact that the more the tissues used reverted to the embryologic type, the greater was the increase in large lymphocytes following its injection. This forced me to the conclusion that we were not dealing with a specific ferment but with a general proteolytic ferment produced by the larger mononuclear leukocytes which is specific only to a limited degree.

This also explained why residues or vaccines made from some forms of malignant tumors gave but a slight increase in large mononuclear cells after injection, while others gave an increase of from 200 to 300 per cent. A careful study of many tumors in this way indicated that the more the tumor reverted to the embryologic type, the greater was the resulting increase.

For this reason it was thought best that a tissue which invariably gave a decided increase when properly prepared should always be used; a residue made from normal placental tissue was found to answer the requirements most satisfactorily.

Consequently we now always use this substance in our tests for the activity of the malignant immune mechanism, unless we have been particularly fortunate in obtaining an extremely malignant sarcoma.

Without going more into detail, it can be quite definitely stated that the immune mechanism in malignancy is a ferment which is formed in the large mononuclear leukocyte. This particular type of blood cell is of splenic origin or arises from similar tissues, notably the hemolymph glands and possibly the bone marrow under certain conditions.

A study of the blood findings in cases of all stages of malignancy was next undertaken. This series comprises over 200 cases ranging from the earliest diagnosable lesion to the most advanced cases, and when added to a survey of 10,000 previous daily counts on patients in all stages of this disease, it furnished some very interesting data.

In general, it may be stated that cases of early malignancy usually show a decided decrease in the total number of polymorphonuclear leukocytes with a corresponding increase in mononuclear cells.

Thus the differential count in early cancer closely resembles that seen in exophthalmic goiter, syphilis and tuberculosis, the percentage of polymorphonuclear cells being frequently much below 60.

When a tumor is growing rapidly, and always after metastasis has taken place, the percentage of polymorphonuclear cells runs above 70, and is usually much higher.

The differential count in early malignancy frequently varies considerably from day to day, and more decided changes are noticed at longer intervals.

When a high percentage of large mononuclear cells is noted for several days in succession, the tumor retrogresses during that period. Conversely, when the count shows a high percentage of polymorphonuclear cells for a continued period, it signifies rapid tumor growth. Indeed, during such periods, the microscopic character of the tumor cells occasionally assumes a more malignant type. This is evidenced in a case in which the first tissue was removed from the thyroid gland when the differential count was: polymorphonuclears, 50 per cent.; large mononuclears, 12 per cent.; small mononuclears, 38 per cent.; eosinophils 0, and the section shows a carcinoma simplex. The second section was taken from the same individual when the count was running: polymorphonuclears, 85 per cent.; large mononuclears, 2 per cent.; small mononuclears, 13 per cent.; eosinophils, 0, and shows what might have been called a spindle cell sarcoma. Such an apparent change in tumor morphology has been observed in four different instances.

The study of this large series of blood counts, besides furnishing the foregoing scientific data, revealed one fact of decided clinical importance, namely, that metastasis does not usually occur until the percentage of polymorphonuclear cells becomes high and remains so. In other words, metastasis does not occur until the immune mechanism has broken down and is no longer capable of being stimulated to renewed function.

Neighboring lymph glands may be slightly involved while the immune mechanism is still intact, but no advanced metastasis can occur during this period.

From this it can be seen that if the first differential leukocyte count in any case of malignancy shows a high large mononuclear count and a low polymorphonuclear count, we can conclude that metastasis has not occurred, and that the case is operable.

If the count shows a high polymorphonuclear and a low mononuclear percentage then we have at our disposal the wherewithal to test whether the immune mechanism has been destroyed or whether it is simply an interval of increased tumor growth. This is ascertained by injecting about 1 c.c. of placental residue intraperitoneally into the patient, and taking daily differential blood counts thereafter.

A twenty-four to forty-eight hour decrease in polymorphonuclear cells signifies that the immune mechanism is still intact and that metastasis has not occurred and therefore that the case is operable. No change, or an increase in polymorphonuclear cells with a corresponding decrease in large cells, shows inoperability because of metastasis. Such patients actually receive harm and their end is hastened by surgical intervention, unless such a procedure is indicated for palliative reasons.

In order to better illustrate this point let me cite two cases that were clinically similar in every respect. They were both cases of gastric carcinoma, apparently of advanced type, and the roentgenologist reported both inoperable.

Case 1 (235).—Carcinoma of stomach. Hemoglobin, 70 per cent. Differential leukocyte count: polymorphonuclears, 75 per cent.; large mononuclears, 6 per cent.; small mononuclears, 18 per cent.; eosinophils, 0; mast cells, 1 per cent.

Injection of placental residue, twenty-four hour count: polymorphonuclears, 82 per cent.; large mononuclears, 3 per cent.; small mononuclears, 15 per cent.

Case 2 (241).—Carcinoma of stomach. Hemoglobin, 40 per cent. Polymorphonuclears, 70 per cent.; large mononuclears, 6 per cent.; small mononuclears, 23 per cent.; eosinophils, 1 per cent.

Injection of placental residue, twenty-four hour count: polymorphonuclears, 59 per cent.; large mononuclears, 15 per cent.; small mononuclears, 25 per cent.; mast cells, 1 per cent.

The test in Case 1 showed that the immune mechanism was destroyed, and therefore the diagnosis of metastasis present was made.

Operation was performed for obstruction, and a posterior gastro-enterostomy was made. At this time, liver metastasis and extensive lymph gland involvement were found, and the postmortem two months later revealed extensive retroperitoneal involvement, both suprarenals being almost destroyed.

Case 2, which clinically appeared much farther advanced owing to the severe secondary anemia, showed a decided decrease in polymorphonuclear cells following injection, and an increase in large lymphocytes. From this the low hemoglobin was attributed to slow hemorrhage, since the test showed the immune mechanism to be intact, and a diagnosis of no metastasis was made. At operation a small growth obstructing the pylorus was found, and a radical operation was performed. No metastasis was observed. The lymph glands of the lesser curvature were decidedly enlarged, but microscopic section of these showed them to be inflammatory and that no metastasis was present.

We have followed the foregoing routine in over 200 cases, and I feel justified from the uniformity of our observations in stating that if the test shows the immune mechanism to be intact, operative treatment is indicated. Conversely, if the test shows the immune mechanism to be destroyed, operation is useless except for palliative reasons.

Again, I believe that operation is best performed when the percentage of large mononuclear cells is high, as metastasis is less liable to occur from the operative handling if the anticancer ferment is active when the operation is performed.

One more word concerning the value of this test: It is a valuable prognostic aid. After complete destruction of the immune mechanism, which may occur occasionally when the initial tumor is small, the progress of the disease is always rapid, and operation in such cases is usually followed by rapid general metastasis, while many cases, apparently far advanced, will respond to stimulation of the immune mechanism. Such patients always live much longer than the physician anticipates, unless he is particularly guarded in his prognosis. It is this class of case, with the alternating periods of retrogression and advancement of growth, that furnishes the fruitful field for the work of the charlatan, since the temporary benefit observed from Nature's efforts is usually attributed to whatever medication is being used at the time.

ABSTRACT OF DISCUSSION

Dr. Henry Schmitz, Chicago: I made the assertion some time ago, and again here in discussing Dr. Levin's paper, that in the study and treatment of carcinoma we should take into consideration the leukocytic and the differential white blood corpuscle count. By these the value or uselessness of different therapeutic measures could be shown. If, for example, following the use of a certain therapeutic measure, there were a decrease in the red and the white blood count, we should wait until the blood returned to normal before making another attempt to treat the patient. If the decrease persists, further treatment would be useless. This is specially true in the radium and roentgen treatment of cancer. Persistence of leukopenia indicates the hopelessness of the treatment. Additional exposures to the rays merely render the patient and the tumor worse. I therefore feel that the observations of Dr. Vaughan are of inestimable value, not only in the determination of operability, and the prognosis of surgical treatment of carcinoma, but also of the palliative treatment. On my return home I shall immediately begin a study of my work from Vaughan's standpoint and see whether I can substantiate his deductions.

Dr. Samuel W. Bandler, New York: I am delighted to hear the word immunity introduced in the study of carcinoma. I believe the preventive study will be along the line of immunity—determining why some of us have it and others do not. It would be interesting also in families to study whether the tendency to carcinoma is a characteristic of more than one member of the family or only of the person who has the disease. I have known histories in which the father has had carcinoma, in which three children have died in infancy; one adult child of that father has tuberculosis; another adult daughter has carcinoma of the stomach at the age of 37; another adult daughter has carcinoma of the colon at the age of 34. Circumstances such as that point absolutely to a lack of resistance in that family, which takes the form of carcinoma in the majority, of tuberculosis in one, and death in infancy or childhood in the others. It would be interesting to see in these cases whether there is a familial change in the blood and in the relation of the cells in other members of the family than the one with carcinoma. I would ask whether Dr. Vaughan has made studies of the same sort in benign tumors of various parts of the body, pointing to immunity in one individual and a lack of it in another. In women who have been pregnant we find in a certain proportion the development of hydatid mole, or an overgrowth of cells which are supposed to atrophy and disappear, showing a lack of protection or resistance in that individual.

Dr. J. Walter Vaughan, Detroit: The only studies we made with benign tumors were in making extracts from the tumors and testing out their power to increase the percentage of large mononuclear cells. The more the tissue cells revert to embryologic type, the higher the increase—from 6 to 10 per cent. I am glad that the point has been brought out that the repeated differential blood count is of the utmost importance and gives us more aid clinically than any other examination.

RELATION OF VITAL CAPACITY OF LUNGS TO CLINICAL CONDITION OF PATIENTS WITH HEART DISEASE *

CHARLES W. McCLURE, M.D.
AND
FRANCIS W. PEABODY, M.D.
BOSTON

In most persons with heart disease, dyspnea is one of the earliest symptoms observed, and the tendency of a patient to become short of breath on exertion bears a close relation to his clinical condition. The physician often asks of his patient, "Do you get short of breath easily?" or "Do you get short of breath more easily than you did formerly?" and thereby indicates that he regards the question of dyspnea as having a direct bearing on the functional state of the heart. An increasing tendency to dyspnea is evidence of a failing cardiac reserve, while the ability to perform a greater amount of exercise without becoming short of breath indicates, in general, an improvement in the efficiency of the heart. In a limited number of patients, palpitation or cardiac pain are the presenting symptoms, and dyspnea does not assume so prominent a rôle, but in a much larger group the onset of respiratory distress is the first symptom which suggests that the subject is approaching the limit of the functional capacity of his heart.

On account of the importance of the tendency to dyspnea as an index of the clinical condition of the patient, we not infrequently attempt to standardize it or describe it in our records, so that we may know more or less accurately whether it is increasing, decreasing or remaining constant. Unless, however, careful observations are made on the patient while he is undergoing graduated exercises, one has little but the patient's own statement to rely on, and such observations concerning subjective symptoms are, of course, apt to be extremely vague and unreliable. It would be of considerable assistance, therefore, if we could devise some objective method of measuring accurately the tendency to dyspnea. The latter it seems possible to do in the determination of the vital capacity of the lungs.

As a result of a study of the various elements which take part in the production of dyspnea in heart disease, it was found that perhaps the most significant feature was the inability to breathe deeply. When a person

---

* From the Medical Service of the Peter Bent Brigham Hospital, and the Department of Medicine, Medical School of Harvard University.

* Read before the Section on Practice of Medicine at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

exerts himself, as by walking or running, the metabolism becomes increased, the oxygen consumption is raised, and in order to meet the need for additional oxygen, the rate and depth of respiration are increased. The normal subject accomplishes this without difficulty, since he can easily breathe many times deeper than he does while he is at rest; but for the patient with severe heart disease, it is quite a different problem, for the amount to which he can increase the depth of his respiration is much restricted. If one measures the vital capacity of the lungs of such a patient, and this is the volume of air which he can expire after the deepest possible inspiration, it will be found to be much below the normal. The importance of this inability to breathe deeply, which manifests itself as a decrease in the vital capacity of the lungs, is shown still further by the fact that there is a close relationship between the degree of the decrease in vital capacity and the degree of the tendency to dyspnea. Observations reported elsewhere on 124 patients[1] and many subsequent observations confirm this fact. If the volume of the vital capacity is expressed in terms of the percentage of normal values determined according to sex and height,[2] it has been found that the following generalizations are approximately true: Cardiac patients with a vital capacity of 90 per cent. or more of the normal standards have no more tendency to dyspnea than is to be found in a similar group of healthy persons. Cardiac patients with a vital capacity of from 70 to 90 per cent. of the normal almost invariably give a history of becoming short of breath on moderate exertion, but most of them can lead a satisfactory although somewhat limited life. Patients with heart disease who have a vital capacity which is only from 40 to 70 per cent. of the normal are much more restricted. Practically all become short of breath easily, and few are able to do even the lightest work. They are borderline cases and frequently become acutely decompensated. Those patients with a vital capacity which is below 40 per cent. of the normal standard are acutely decompensated, usually confined to bed, and are often dyspneic even while at complete rest.

It having been shown that there is a direct relation between a decrease in the vital capacity of the lungs and the clinical condition of cardiac patients even when one compares the vital capacity of the individual case to more or less arbitrarily chosen normal standards, it seemed worth while to find out whether this relation between vital capacity and clinical condition would not be even more striking if frequent observations were made in the same case. In a considerable

TABLE 1.—VITAL CAPACITY DURING PROGRESS OF CARDIAC DISEASE

	5/ 2	2,500	52	Stationary	
	5/ 5	2,100	44	Worse	Edema of legs; liver large and tender
	5/ 7	2,300	48	Stationary	
	5/ 9	2,300	48	Stationary	Left hosptal, but gets short of breath very easily

---

[1] Peabody and Wentworth: Arch. Int. Med., September, 1917, p. 443.

[2] The normal values for the vital capacity of the lungs are: Males: Height from 159.5 to 173.5 cm., 4,000 c.c.; from 173.5 to 182.5 cm., 4,800 c.c.; 182.5 cm. and above, 5,100 c.c.. Females: Height from 154.5 to 162 cm., 2,825 c.c.; from 162 to 167 cm., 3,050 c.c.; 167 and above, 3,275 c.c.

group of cases, therefore, we have attempted to plot the variations in the vital capacity of the lungs and to compare with these the changes in the clinical condition. Each observation has consisted of a careful clinical examination of the patient, together with the recording of a statement as to whether the examiner considered the patient's general condition to be improved, worse or stationary, and then the determination of the vital capacity of the lungs. Instead of the recording spirometer which was used in the previous observations on the vital capacity of the lungs, in this series of cases we have used an ordinary well-balanced spirometer of 8 liter capacity. The subjects *were told to take as deep an inspiration as possible,* and then to insert the tube to the spirometer into the mouth and give a complete expiration. The volume of the expiration was measured on the spirometer wheel. In a few subjects who were very ill or were for other reasons unable to cooperate, and in a few who were unwilling to cooperate, satisfactory results could not be obtained, but in most instances it proved to be comparatively easy to get records that apparently represented with considerable accuracy the vital capacity of the lungs.

TABLE 2.—EFFECT OF EDEMA ON VITAL CAPACITY

Case	Date	Vital Capacity		Condition	Remarks
		C.c.	%		
6 Med. No. 6229 Mitral stenosis Auricular fibrillation	3/ 3	1,900	47	....	Orthopnea; cyanosis; edema of legs
	3/ 4	1,800	45	Improved	Less edema of legs
	3/ 5	1,900	47	Improved	Less edema and has dyspnea
	3/ 7	2,300	56	Improved	Less dyspnea; less edema of legs
	3/ 9	2,500	62	Improved	Improved; breathing easier
	3/12	2,400	60	Stationary	
	3/16	2,200	55	Stationary	
	3/19	2,400	60	Stationary	
	3/26	2,200	58	Stationary	Some edema of legs; out of bed, but becomes dyspneic on slight exertion

	5/ 7	2,150	54	Improved	Less dyspnea; no edema and no ascites
	5/ 9	3,500	88	Improved	No dyspnea
	5/16	3,600	90	Stationary	Out of bed and in good condition

Judgment as to the clinical condition of our patients has been based on the degree of dyspnea, edema, pleural transudate, ascites, pulmonary congestion, acute enlargement of the liver, cyanosis, and pulse rate or pulse deficit. In two cases, of which special mention will be made, precordial pain and cutaneous or muscular hyperesthesia were considered as symptoms of myocardial weakness.

Twenty-four patients with some severe form of cardiac disease have been studied. In five patients in whom the objective evidences of myocardial *insufficiency* were marked, the alterations in clinical condition took place extremely slowly. For this reason it was frequently difficult or even impossible to note any changes in observations made at short *intervals.* It was under these circumstances that the greatest discrepancies between the vital capacity records and our judgment of the progress of the case have occurred. Nevertheless these discrepancies have never been great, and the subsequent course of the case has invariably shown an error in judgment rather than an error in the indications of the vital capacity records. A comparison of our clinical observations as to the progress of the case with the vital capacity findings is given in Table 1.

Diminution in edema of the extremities resulting from rest in bed does not necessarily represent improvement in the functional condition of the myocardium. It may be explained as a static phenomenon resulting from a change from the vertical position assumed in sitting or standing to the horizontal position in bed. On the other hand, edema, while apparently leaving the body, may merely be redistributed, as is sometimes shown by the failure of the patient to lose weight (Table 2).

Two frequent complications of cardiac disease which modify the vital capacity are hydrothorax and ascites. It is to be expected that the vital capacity would increase corresponding to the diminution of the amount of fluid in the pleural or peritoneal cavities. The findings in the patients we have studied in whom either hydrothorax or ascites, alone or combined, were present are given in Table 3.

TABLE 4.—EFFECT OF ANGINOID PAIN OR CUTANEOUS AND MUSCULAR HYPERESTHESIA ON VITAL CAPACITY

Case	Date	Vital Capacity		Condition	Remarks
		C.c.	%		
15 Med. No. 6176 Mitral stenosis	2/21	2,450	80	....	Cyanosis; frequent cough; slight edema; no dyspnea
	3/ 1	2,950	97	Improved	No edema; less cough
	3/ 5	2,200	72	Worse	Precordial pain
	3/ 9	2,700	89	Improved	No pain; left hospital in good condition
16 Med. No. 6480 Mitral stenosis	4/20	2,000	61	....	Dyspnea on exertion; comfortable in bed
	4/27	1,900	60	Stationary	
	4/20	2,400	73	Improved	Subjective improvement
	5/ 2	2,600	80	Stationary	
	5/ 9	2,000	61	Worse	Cutaneous and muscular hyperesthesia
	5/10	2,100	64	....	Hyperesthesia unchanged
	5/14	2,965	91	Improved	Hyperesthesia gone
	5/15	3,000	91	Stationary	
	5/18	3,000	91	Stationary	
	5/25	3,100	94	Stationary	Condition good; walking about the ward
17 Med. No. 6262 Mitral stenosis Aortic insufficiency	3/ 9	1,100	39	....	Orthopnea on slight exertion; moderate edema of legs
	3/10	1,200	42	Improved	Less edema
	3/12	1,375	48	Improved	
	3/16	1,650	58	Stationary	Vital capacity is increased, but no change noted in clinical condition; still in bed
	3/19	1,500	53	Stationary	
	3/22	1,850	65	Improved	Less cyanosis; less dyspnea; no edema
	3/26	1,900	66	Stationary	Gets dyspneic on moderate exertion
18 Med. No. 6293 Chronic myocarditis	4/ 7	1,900	48	....	Acutely decompensated tender, pulsating liver; no dyspnea while in bed
	4/10	2,400	60	Improved	Liver not palpable
19 (Chart 3) Med. No. 6130 Chrone myocarditis Auricular fibrillation	2/13	1,700	42	....	Marked dyspnea; orthopnea; much edema of legs
	2/14	2,175	54	Improved	Less dyspnea; less edema
	2/16	2,800	70	Improved	Less edema; less dyspnea
	2/19	3,200	80	Improved	Less edema; less dyspnea
	2/23	3,150	79	Stationary	
	2/27	2,550	88	Stationary	Less cough
	3/ 1	3,550	88	Improved	
	3/ 5	3,200	80	Stationary	
	3/ 8	3,450	86	Stationary	
	3/12	3,575	89	Stationary	General condition good; walking about the ward
20 Med. No. 6135 Mitral stenosis	2/14	1,200	42	....	Much dyspnea even when at rest
	2/15	1,275	45	Improved	Less dyspnea
	2/17	1,400	49	Improved	Slight edema
	2/18	1,200	42	Worse	More dyspnea
	2/24	1,400	49	Improved	Less dyspnea; comfortable in bed
	2/27	1,475	52	Stationary	
	3/ 1	1,400	49	Stationary	
	3/ 4	1,650	58	Stationary	
	3/ 5	1,575	55	Stationary	Up in chair; dyspnea on slight exertion
21 Med. No. 6191 Mitral stenosis	4/25	1,900	68	....	Dyspnea on exertion, but comfortable in bed
	4/26	1,800	64	Stationary	
	4/27	1,950	69	Stationary	
	4/30	1,950	69	Stationary	
	5/ 2	2,000	71	Stationary	
	5/ 9	2,100	74	Stationary	
	5/15	2,200	77	Improved	Less dyspnea on exertion
	5/18	2,200	77	Stationary	Out of bed; no dyspnea while walking about ward
22 Med. No. 6241 Chronic myocarditis Auricular fibrillation	3/ 4	3,100	78	....	Dyspnea; cyanosis
	3/ 5	3,500	88	Improved	Much better; less dyspnea
	3/ 8	3,500	88	Stationary	
	3/12	3,475	87	Stationary	
	3/16	3,600	90	Stationary	
	3/19	3,500	88	Stationary	
	3/22	3,500	88	Stationary	No dyspnea when walking
23 Med. No. 6273 Chronic myocarditis	3/13	2,475	51	....	Slight edema of shins; dyspnea; cough
	3/14	2,400	50	Stationary	
	3/16	2,300	48	Stationary	
	3/19	2,500	52	Improved	No edema of shins; much cough
	3/22	2,300	48	Stationary	Less cough
	3/26	2,600	54	Stationary	Much cough; râles in both lungs; no noticeable change in condition since entering hospital
24 Med. No. 6399 Mitral stenosis	4/ 7	2,500	63	....	Slight dyspnea at rest; bloody sputum
	4/10	3,100	78	Improved	No dyspnea at rest; no sputum
	4/17	3,400	85	Stationary	
	4/20	3,200	80	Stationary	
	4/23	3,500	88	Stationary	Out of bed
	4/27	3,400	85	Stationary	Condition unchanged
	5/ 5	3,200	80	Stationary	
	5/ 7	2,800	70	Worse	Increased dyspnea
	5/ 9	3,000	75	Stationary	
	5/15	3,100	78	Stationary	
	5/17	3,400	85	Improved, stationary	
	5/23	3,400	85	Stationary	Left hospital in good condition

In six of the eight cases outlined in Table 3 the hydrothorax and ascites disappeared while the patients were under observation. After the disappearance of the pleural and peritoneal fluid, the vital capacity continued to increase to the extent of from 4 to 6 per cent. in three cases, and 10, 12 and 36 per cent. in the other three. The findings indicate that the decrease in the vital capacity in these cases depended in part on the factors other than the hydrothorax and ascites.

Mackenzie has long believed that anginoid pain or cutaneous and muscular hyperesthesia were evidence of myocardial insufficiency. It is interesting to note that with the onset of such symptoms in two otherwise uncomplicated cases of mitral stenosis, the vital capacity dropped markedly, to rise again with the cessation of symptoms. In one of these cases there was a rather sharp anginoid pain over the precordium. In the other case there was marked cutaneous hyperesthesia over the front of the left chest, over the pectoral muscles, and also over the trapezius muscle in the neck. Deep inspiration did not cause pain in either case. The vital capacity findings are given in Table 4.

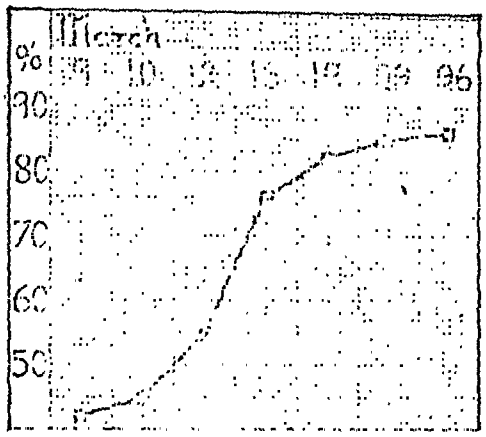

Chart 1—Vital capacity in Case 11.

The vital capacity in a patient with paroxysmal tachycardia was studied during and after an attack. There were no evidences of organic heart disease, and during the paroxysm there were no symptoms referable to the heart. Sixteen hours after the onset of a paroxysm in which the heart rate was 180 per minute, the vital capacity was 58 per cent. Two days late, and twenty-four hours after cessation of the tachycardia, the vital capacity had increased to 83 per cent. A continued rapid rate of the heart in paroxysmal tachycardia is frequently accompanied by marked signs of myocardial insufficiency, but in our case the lowered vital capacity was the only indication of this. The accompanying charts show graphically the changes in the vital capacity in three typical cases (11, 12 and 19). Such charts are excellent objective records of the clinical course which each of the patients has passed through.

REPORT OF THREE TYPICAL CASES

Case 11 (Med. No. 6261).—*Chronic myocarditis, auricular fibrillation, hyperthyroidism.*—Woman, aged 39, white, admitted, March 9, 1917, discharged, March 30, 1917, had had exophthalmic goiter for the last eight years. Six years ago she had a break in cardiac compensation, since which time her feet had been edematous at different periods. On entrance to the Peter Bent Brigham Hospital there were orthopnea, double hydrothorax and considerable edema of the legs. The usual findings of exophthalmic goiter were present. The area of cardiac dulness measured 19 cm. to the left in the fifth interspace and 2 cm. to the right in the fourth interspace. The cardiac action was absolutely irregular. A systolic murmer was audible over the region of the apex of the heart. Blood pressure was 142 mm. systolic and 90 mm. diastolic. The electrocardiographic diagnosis was auricular fibrillation.

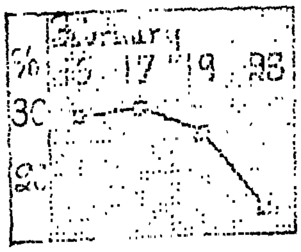

Chart 2.—Vital Capacity in Case 12.

March 10, there was less edema of the legs than was present on admission.

March 12, the edema of the legs had subsided. There was less fluid in the pleural cavities.

March 16, hydrothorax was no longer present.

March 19, 22 and 26, the vital capacity had increased 10 per cent. since March 16. During that time the patient's physical condition had much improved. The pulse rate had diminished from 80 to 90 to from 60 to 70 per minute, and the heart was well compensated.

Case 12 (Med. No. 6152).—*Mitral stenosis and insufficiency, myocardial insufficiency, auricular fibrillation, bronchitis, syphilis.*—Man, aged 53, white, admitted, Feb. 15, 1917, died, Feb. 24, 1917, had been told ten years before that he had a valvular heart disease. During the last four years the patient had had occasionally a little dull precordial pain, and also some dyspnea on unusual exertion, and momentary attacks of vertigo. For several years his memory had been faulty, and he had become definitely irritable in disposition. The present illness began three months before with the symptoms of acute bronchitis and dyspnea, which had grown progressively worse. For the last week before admission to the Peter Bent Brigham Hospital the legs had been swollen. Physical examination showed marked orthopnea, anasarca, and deep cyanosis of the face, lips, ears and fingers. The area of cardiac dulness measured 14 cm. to the left in the fifth interspace and 45 cm. to the right in the fourth interspace. The heart's action was absolutely irregular, and there was a pulse deficit of 38 to the minute. There was a systolic murmur audible over the entire precordium, loudest in the region of the apex of the heart. In the longer pauses between heart beats a short early diastolic murmur was heard at the apex. Blood pressure was 130 mm. systolic and 90 mm. diastolic.

February 17, the patient was slightly worse. There was an increase in the edema of the scrotum, and the patient's cough was more frequent. However, there was less cyanosis than on admission.

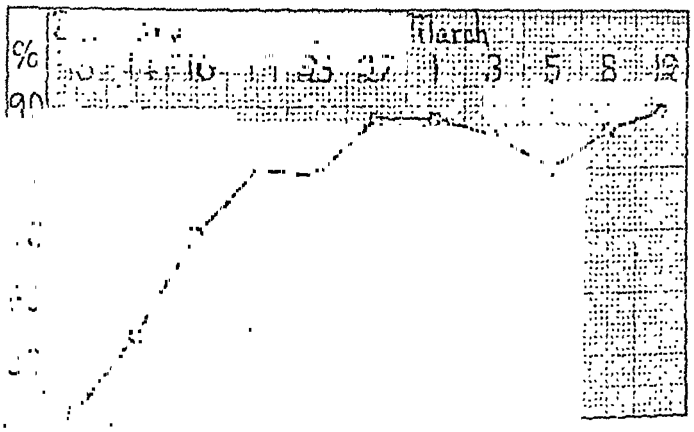

Chart 3—Vital capacity in Case 19.

February 19, the patient's condition was unchanged.

February 23, the patient was decidedly worse. He appeared to be much weaker physically. The cough was more frequent. He died several hours after the last vital capacity record had been obtained.

Case 19 (Med. No. 6130).—*Chronic myocarditis, hypertension, auricular fibrillation, chronic nephritis.*—Man, aged 63, white, admitted, Feb. 12, 1917, discharged, March 13, 1917, had unimportant past medical history. The present illness began ten weeks before admission to the hospital with some generalized weakness, slight dyspnea, and fatigue on exertion. For the last three weeks the patient has been dyspneic. Physical examination revealed that the patient was orthopneic. There was considerable edema of the legs. There were coarse râles throughout both lungs. The area of cardiac dulness measured 16 cm. to the right in the fourth interspace. The heart's action was irregular, and the cardiac sounds were but faintly audible. No murmurs were heard. The aortic second sound was accentuated. Blood pressure was 190 mm. systolic and 90 mm. diastolic. An electrocardiogram showed the condition of auricular fibrillation to be present.

February 13, the patient was orthopneic. There was considerable edema of the feet and legs. Numerous coarse moist râles were present throughout both lungs. There was some cough.

February 14, there was much less edema of the feet and legs. Cough persisted.

February 16, the edema of the feet and legs had almost disappeared. But few râles were present in the lungs. Cough persisted.

February 19, the patient lay comfortably in the prone position. The cough persisted.

No change occurred in the patient's condition until March 1. The cough was much less and there was little sputum.

March 3, 5, 8 and 12, the patient's condition remained stationary.

March 13, the patient was discharged from the hospital able to return to his work as a cabinet maker.

SUMMARY

Attention is called to the importance of a decrease in the vital capacity of the lungs as a factor in the production of dyspnea in heart disease. The degree to which the vital capacity is decreased below certain normal standards corresponds closely to the tendency to dyspnea. Since the tendency to dyspnea depends largely on the functional capacity of the heart, the determination of the vital capacity of the lungs may serve as an indirect measure of the cardiac condition. In a series of twenty-four cases it has been found that the clinical condition of cardiac patients varies closely with the changes in the vital capacity of the lungs. An improvement in the functional state of the heart is associated with a rise in the vital capacity. When the condition of the heart is apparently remaining stationary, changes in the vital capacity are not marked, and when there is evidence of increasing cardiac insufficiency, the vital capacity of the lungs falls. Charts showing the variations in the vital capacity of the lungs of patients with heart disease are frequently satisfactory objective records of the clinical course of the disease, and they may be of distinct aid in prognosis.

ABSTRACT OF DISCUSSION

Dr. Joseph H. Pratt, Boston: Stimulated by Dr. Peabody's work, Dr. Paul D. White and I began a study of the vital capacity in patients at the cardiac clinic at the Massachusetts General Hospital. We have the records now of fifty patients. We find that the vital capacity corresponds closely to the functional condition of the heart as determined by the ordinary methods. Patients who were short of breath after walking slowly on a level for a distance of one or two blocks had usually a vital capacity of 50 per cent. or less. Ambulatory patients rarely have less than 40 per cent. In one case, however, it was 30 per cent. In diagnosis, the test is of great value in distinguishing between true cardiac weakness and those cases of cardiac neurosis that simulate organic disease of the heart. The difficulty in distinguishing between these two conditions is due to the fact that the first symptoms of cardiac weakness are usually subjective. The patient first notices slight breathlessness on exertion, and this may be present in organic heart disease before anything abnormal is found in the physical examination.

The value of the test was shown strikingly in the following case: A man had been treated in the dispensary for a year for myocardial disease. He complained that he was short of breath when he walked on the level a distance of 100 yards. Although nothing abnormal was found on the examination of the heart, the diagnosis had never been disputed. We found that his vital capacity was normal. From careful inquiry I learned that although he claimed to have a feeling of breathlessness while walking, he was able to run up stairs without any discomfort. This showed conclusively that the subjective sensation of which he complained was not due to cardiac weakness. We had mistaken a cardiac neurosis for organic heart disease.

The method is of improtance in determining the functional capacity of the heart in patients who are in bed. Recently I had under observation at one time three patients with mitral stenosis. All gave a history of shortness of breath on slight exertion. In bed they exhibited no signs of cardiac insufficiency. They were able to lie with their heads low; there was no edema, and the pulse in each case was slow. To have tested their cardiac capacity by allowing them to exercise would have been too hazardous. The vital capacity test was made. Two had 40 per cent., the other about 80 per cent. I had previously suspected that there was a large neurotic element in the patient with the high vital capacity. Encouraged by the result of this test she has been taking recently, without discomfort, more exercise than she had for several years. The results of treatment among our ambulatory patients has not been encouraging as measured by the vital capacity test, and in only one case has there been a marked increase in the vital capacity from the use of digitalis, with the patient up and about. In this case, which was one of auricular fibrillation, the increase amounted to 25 per cent.

Dr. T. B. Barringer, Jr., New York: I am able in many ways to confirm the results which Dr. McClure has obtained. In estimating the vital capacity in cardiac patients I have found that it is much lower than in normal persons, and the greater the insufficiency, the lower the vital capacity. In cardiac patients with normal reserve power I have found that the vital capacity is normal. In cardiacs with low reserve power, but no insufficiency, the vital capacity is frequently normal. I have felt that the decrease in vital capacity in cardiac insufficiency was due to the congestion of the lungs which was present. In the treatment of patients by graduated exercises I have found that as the heart's reserve power increases and the clinical condition of the patient improves, the vital capacity goes up. Two years ago I drew attention to a small series of cases in which the average increase of vital capacity during the course of treatment was 25 per cent.

Dr. R. G. Pearce, Cleveland: I have an interesting case which Dr. Hoover and I saw in Lakeside Hospital, in which we estimated the vital capacity of the lungs and the cardiac output by the method proposed by Christianson, Douglas and Haldane, which determines the blood flow through the lungs per minute; that is, cardiac output of the right ventricle. The man had a badly decompensated heart. He had a vital capacity of about 1.2 liters and a cardiac output of 3 liters. After a course of digitalis for three days he had a vital capacity of 1.8 liters and a blood flow per minute of 4 liters. After a week he had 2.4 liters vital capacity and a blood flow of 4.5 liters per minute. The normal man has a cardiac output of 5 or 6 liters per minute. I think this observation is interesting because it checks up cardiac output with vital capacity.

Dr. C. W. McClure, Boston: A study has been made of cardiac patients who were compensated, and it has been found, as I tried to bring out early in the paper, that the vital capacity in patients with cardiac disease who we say are compensated varies in different patients. If the patient can lead a normal life, the vital capacity is almost invariably above 90 per cent. If the patient is able to do a slight amount of work, but must lead a restricted life, the vital capacity will fall almost invariably to somewhere between 70 per cent. and 90 per cent. of the normal. Patients whose vital capacity is less than 70 per cent. are dyspneic on very moderate exertion. The lower the vital capacity, the easier the patient becomes dyspneic, and patients who are down near 40 per cent. are usually decompensated or become decompensated very easily.

A New Method of Cleaning Slides.—The method of cleaning old used slides given below is new so far as the writer knows, and as it is simple, cheap and effective, it seems to merit publication. The only reagent necessary is commercial (household) ammonia used full strength. The slides are soaked in this indefinitely (at least twenty-four hours), when it will be found that they can be rinsed in water and wiped clean. Stained smears of all kinds covered with immersion oil and tissue sections mounted in balsam are all equally well cleaned. The immersion oil need not be removed before soaking, although it is advisable to wipe off the excess. The ammonia may be used repeatedly if kept in a receptacle with a tight cover to prevent loss.—Reuben A. Johnson, M.D., Minneapolis.

SALVARSAN AND NEOSALVARSAN MYELITIS

REPORT OF A FATAL CASE

G. W. McCASKEY, M.D.
FORT WAYNE, IND.

It is not surprising that, when so fatal a disease as syphilis of the central nervous system is attacked with a drug so powerful as arsenic, serious results should now and then occur. The gravity of the disease and its general tendency toward fatality, however, fully justify the risk in view of the beneficial results so commonly observed. Only a few cases of myelitis have been so far recorded, although it is probable that a considerable number of unrecognized cases have occurred or been reported under more general captions. Perhaps the most common neurotoxicologic result of the administration of salvarsan has been a hemorrhagic encephalitis. In some cases this has been verified by necropsy and histologic examination. In some of the cases, however, which clinically looked like encephalitis nothing was found histologically in the central nervous system.

The following reports are brief outlines of the few cases recorded, together with the description of my own case.

Bayet[1] reported the following case:

Case 1.—A man, aged 24, came under treatment for secondary syphilis, three months after the primary lesion. At that time he was given 0.7 gm. of neosalvarsan intravenously. This was well tolerated, although there was a slight general malaise. Ten days later, August 26, he received 0.8 gm., and immediately thereafter developed fever, with a scarlatiniform eruption. There was vomiting for two days. September 1 he was suddenly found paraplegic. There was bladder paralysis with loss of the superficial and deep reflexes, with the single exception of the plantar reflex. There was no Babinski reflex. The spinal fluid was not under increased tension, contained no lymphocytes, and gave a negative Wassermann reaction. This case was not fatal so far as known, but the subsequent history was not followed up.

Socin[2] reported the following case:

Case 2.—A woman, aged 38, suffering from syphilis, but without any involvement of the central nervous system, was given 0.5 gm. of salvarsan, intravenously. No symptoms followed this treatment. Five days later the same dose was repeated. No symptoms were manifested for forty-eight hours, at the end of which time she began to have a slight elevation of temperature and, later in the day, general convulsions followed by vomiting and complete apathy. There was a leukocytosis of 10,000 with 86 per cent. polymorphonuclears. About a month later an extensive decubitus developed. Motor and sensory paralysis of irregular distribution was present. This patient for a little more than a year had all the symptoms of a severe myelitis, and died of an intercurrent pneumonia.

The following case of myelitis, apparently caused by the intravenous injection of neosalvarsan, was reported by Chiari[3]:

Case 3.—Three months after acquiring a genital chancre, a woman, aged 27, appeared at the clinic with symptoms of secondary syphilis. This was June 1, 1912. That day she received 0.7 gm. of neosalvarsan intravenously. June 4 she was given 1.2 gm., and June 7, 1.4 gm. Immediately following the last injection there appeared a scarlatiniform exanthem that lasted nine days. About the same time that the eruption disappeared, vomiting began, lasting a week. June 13, she began to show symptoms of paralysis of the lower extremities, which soon became complete. June 19, a large decubital ulcer developed over the sacrum and later became quite extensive. During this time she developed albumin and casts and blood in the urine. The further history of the case was that of a severe progressive myelitis, of which she died, December 15, six months after beginning the treatment. This patient also had a terminal pneumonia. The anatomic findings were those of an inflammatory process, especially involving the gray matter of the cord, but to a lesser extent the white substance as well.

My own case of myelitis, which, as far as I can determine, is the fourth case reported under that title, presents the following history:

Case 4.—Miss R., aged 40, first consulted me, Dec. 15, 1915. She presented the typical syndrome of tabes dorsalis: the tabetic gait, lightning pains, loss of the knee jerk, and the Argyll Robertson pupil. The blood Wassermann test was negative. The routine blood examination revealed: hemoglobin, 85 per cent; leukocytes, 12,600; polymorphonuclears, 72 per cent.; small lymphocytes, 22; large lymphocytes, 2; transitionals, 4. The spinal fluid was not under very great pressure, but contained excessive globulin, with 16 lymphocytes per cubic centimeter with a + + + Wassermann reaction. The colloidal gold test showed 0000440005. At a later date the gold test was 2120000000. There was no heart involvement, but a mild grade of interstitial nephritis. The urine had a specific gravity of 1.010, with 44 per cent. phenolsulphonephthalein output in two hours and ten minutes. There was neither albumin, nor sugar, nor casts. The digestive functions were normal. There had been a little diplopia at times, but the eyegrounds were normal on ophthalmoscopic examination.

The patient was placed on the Swift-Ellis treatment at intervals of about two weeks, diarsenol being used intravenously and the blood being taken in about twenty minutes, the serum being given intraspinally on the following morning. The patient improved satisfactorily, and, after a couple of months' time, neosalvarsan, being procurable, was used instead of the diarsenol.

Early in May, after five months of Swift-Ellis therapy, the treatment was changed to the simultaneous combined intravenous and intraspinal injection. After the usual dose of neosalvarsan intravenously (about 0.6 to 0.8 gm.), an intraspinal injection was immediately given with the following technic:

A solution of neosalvarsan is made so that each cubic centimeter contains 100 mg. With a finely graduated pipet 0.05 c.c. is measured into a sterile glass representing 5 mg. This is taken up into a Lüer syringe with 5 c.c. of physiologic sodium chlorid solution. Each cubic centimeter represents 1 mg., and it is very easy to retain in the syringe the exact dose desired.

After the preparation of this dilution the lumbar puncture needle was introduced and as much spinal fluid was removed as was desired for laboratory purposes. The syringe was then directly connected with the lumbar puncture needle in situ, and the spinal fluid allowed to run directly into the syringe, diluting the 1 mg. more or less of neosalvarsan up to 5 or 6 c.c., according to circumstances. The contents of the syringe were then immediately reinjected into the spinal canal. This technic of intraspinal injections is still being used, but the dose does not exceed 1 mg., beginning with about 0.5 mg., and is usually not given on the same date as the intravenous injection, to avoid confusion of reactions.

The patient had been given about four of these treatments at intervals of ten days, the dose of neosalvarsan intraspinally being gradually increased up to 1.8 mg. June 16, the same sized dose was given without any marked reaction, although the symptoms were somewhat more severe than usual. Eight days later, precisely the same treatment was repeated. The reaction immediately following the treatment was not unusually severe. The leg and back pains were perhaps slightly more severe than they had been following previous treatments. On the next day she complained that she could not see well, that the legs were weak, and she was unable to void urine. The slight motor and sensory impairment present in the lower extremities gradually increased to complete paralysis. In the course of from four to five days, signs of a decubital ulcer were found over the sacrum, and this gradually became worse. The patient was taken home from the hospital in about a week's time, after which the symptoms remained about the same. A letter from her physician, dated September 18, stated that she had died from exhaustion, the only additional feature of interest being the enormous extent of the trophic ulcers. There were apparently a number of them over the extremities, and one very large one about 6 inches in diameter and circular in form over the sacrum, which the physician said extended down to and actually laid bare the vertebrae. No necropsy could be obtained.

---

Case 5.—In addition to these cases of salvarsan and neosalvarsan myelitis reported under that title, I have been able to find another undoubted case reported by Wile[4] in discussing the technic of subdural injections. In this case, which was one of ordinary tabes in a man, aged 44, 1 mg. of neosalvarsan was given subdurally, Sept. 24, 1913, the injection being followed for five days by lightning pains and girdle pain. Two weeks later, 2 mg. were given subdurally, and this was followed by lightning pains not so severe as after the first treatment. Ten days later 2 mg. were again given in the same manner. One-half hour after this treatment there appeared extreme pain in the legs followed by urinary retention and paraplegia, and later by decubitus, without doubt the typical picture of acute myelitis. These symptoms grew progressively worse and the patient died, Dec. 5, 1913, about two and one-half months following the treatment. No intravenous injection was given in conjunction with these subdural injections. There seems to be no doubt that this fatal myelitis was due to the subdural injection of 2 mg. of neosalvarsan.

COMMENT

Ravout gave sixty-three subdural treatments of from 4 to 12 mg. of salvarsan in isotonic sodium chlorid solution without ill effect. Wechselmann gave from 0.5 to 3 mg. Wile also gave 3 mg., and I think sometimes considerably more without ill effect.

It is interesting to note that in these five cases of myelitis, with the exception of Wile's case and my own, the medication was intravenous alone. In Wile's case it was intraspinal alone, and in my own case it was intravenous and intraspinal. These cases seem to prove that the myelitis may result alike from the intravenous and the intraspinal medication, and in my own case leaves the question fairly open as to whether the myelitis was the result of one or the other or both.

Socin's case resulted from two doses of salvarsan intravenously, each one containing 0.5 gm., while Chiari's case followed three doses of neosalvarsan of 0.7, 1.2 and 1.4 gm., respectively. Bayet's case followed two doses of 0.7 and 0.8 gm. of neosalvarsan intravenously, eleven days apart, while in my own case at least half a dozen 0.8 gm. doses of neosalvarsan intravenously and from 0.5 to 1.8 mg. intraspinally preceded by several doses of diarsenol with a slightly modified Swift-Ellis technic, had been given.

In Chiari's opinion, these severe degenerative and even destructive effects of salvarsan and neosalvarsan on the central nervous system are due to some abnormal condition of their arsenical content. Obermüller[5] had already collected five instances of arsenical poisoning in which certain definite cord changes had been found. These consisted for the most part of degeneration of the anterior cornua, and of certain fibers in the anterior segments of the cord. There were also occasional hemorrhages into the cord. In Chiari's case of salvarsan myelitis, the histologic changes found in the cord bore a very close resemblance to those described in some of the cases collected by Obermüller; and Chiari, therefore, concludes that in his case of myelitis it was the result of the arsenical content of the salvarsan.

This conclusion may seem too obvious to require confirmation, but such is really not the case. As a matter of fact, we are dealing with very complex molecules of the atoxyl series, which undoubtedly undergo fundamental changes within the blood and tissues, giving rise to many intermediate bodies. These chemical reactions and interactions, quite possibly, if not probably, vary widely in different cases. It is known that some of these compounds are intensely toxic, and the conclusion that the myelitis is the direct result of the arsenic finally separated, for example, from the salvarsan molecule in the course of the retrograde chemical changes, instead of some of these intermediate bodies, has something more than a theoretical interest. It can be fairly assumed that many of the unpleasant and serious reactions following the administration of neosalvarsan are due to some of the intermediate bodies above referred to, of the exact nature of which we are for the most part ignorant. In the course of my own clinical observation, I have seen a considerable number of reactions, such as scarlatiniform eruptions, anuresis, chills and fever, intense headache, back and limb pains, and circulatory and digestive disturbances, which, to say the least, were unpleasant and sometimes positively alarming. Reactions of somewhat milder type are certainly very common after the intravenous method. Whether these milder reactions differ only in degree from the severer ones is difficult to determine. It would seem probable that slight neurotropic, or other transient structural alterations, might occur in various organs, from which recovery might rapidly ensue. It would seem that we are constantly confronted with the remote possibility of a catastrophe, such as a hemorrhagic encephalitis or a myelitis. In view, however, of the enormous number of intravenous injections that have been given, running up as they do into many millions, the probability of such accidents must be exceedingly remote.

Wechselmann[6] is of the opinion that they cannot be explained on purely toxicologic grounds. Clinical observation does, indeed, seem to indicate that the drug alone cannot be wholly responsible for the results. The observation of Querst, for instance, in which eight patients received injections from the same solution, one after the other, the fourth one being fatal, not only proves this but also proves that the fatality was not due to oxidation products caused by standing too long, because the four patients later injected from the same solution remained well.

It does seem, indeed, that there must be something in the chemistry of the patient's body fluids which in some way by its action on salvarsan produces toxic bodies, and it would seem most probable that it is due to some of the abnormally toxic intermediate bodies above referred to. It is, of course, necessary to assume fundamental differences in the chemical bodies found in the organism on one day from those found on another. Such an assumption, however, is plausible enough in the light of well known facts along this line.

[6] Wechselmann: Salvarsan Fatalities, 1913, p. 8.

As Wechselmann points out, the fact that it is not usually the first dose that causes the damage militates strongly against the theory of a primary hypersensitiveness. It seems to me, however, that there still remains the possibility of a sensitization by the first dose somewhat along the lines suggested by this term in a strictly biologic sense, or possibly a very slight initial damage, which makes the tissues more vulnerable to subsequent doses.

Welchselmann's statement that insufficiency of the kidney is the point of the entire question of salvarsan fatalities has in it a ring of finality; but, in spite of his absolute preeminence as an authority on this question, this appears to me to be dogmatic. In his own case of salvarsan fatality, for instance, the patient received only 0.2 gm. It is difficult to believe that the moderate grade of renal insufficiency (which alone would be likely to be overlooked in salvarsan therapy) could cause a larger accumulation of the drug within the nerve centers than would probably occur with perfectly normal kidneys after the administration of doses at least seven or eight times as large, which have been repeatedly given without injury. It is not my intention to pursue the general discussion of the question of salvarsan fatalitities further than to consider its bearings on the question of myelitis. It is interesting to note that in encephalitis hemorrhagica produced by salvarsan, the blood vessels alone seem to be damaged, while the neurons remain intact, this point being confirmed by the careful study of the brain cells by Nissl.

CONCLUSIONS

1. Severe and even fatal myelitis may, though rarely, result from even small doses of salvarsan or neosalvarsan given either intravenously or subdurally.
2. This accident may happen without warning in cases in which the same treatment with identical doses had been well tolerated before.
3. It is not always, if at all, due to faulty manufacture, as the same solution has proved fatal to one and innocuous to others given within the same hour both before and after the fatal dose.
4. Wechselmann's conclusion that renal block furnishes the explanation of salvarsan fatalities seems entirely untenable.
5. The most plausible hypothesis seems to me to be the action of toxic compounds in the form of intermediary bodies with especial affinity for the neurons formed in the retrograde changes which occur in the salvarsan compounds and which may vary in different individuals and in the same individual at different times, and of the exact nature of which we are entirely ignorant.
6. Considering the enormous number of these treatments given, the occurrence of myelitis is so rare that it should be ignored as a negligible possibility.

Autocracy and Democracy.—Autocracy finds its strength in its ability to impose organization by force from the top. The essence of democracy consists in the application of the initiative in its own people. If individualism cannot be so organized as to defend itself, then democracy is a faith which cannot stand. We are seeking to impose no organization from the top. We are asking the American people to organize from the bottom up, and this is the essence of democracy itself.—*Weekly Bulletin.*

EDEMA AS A DANGER SIGNAL IN THE STARVATION TREATMENT OF DIABETES

ALFRED C. CROFTAN, M.D.
CHICAGO

Since the popularization of the starvation method in newspapers and magazines, diabetics who had been carried along comfortably and safely for years have been clamoring for starvation. When their regular physician would not adopt the treatment, pilgrimages were undertaken to institutions that featured this cure.

My personal experience teaches me that in mild cases and cases of medium severity this rigorous plan is quite superfluous, and in certain types of the disease more dangerous than the old established methods. There is this advantage in the method, that the period of protein starvation that inaugurates every tolerance determination is materially shortened. This is not new, or altogether safe; it is advantageous chiefly from the economic standpoint by reducing the length of the hospital period.

As to tolerance, I have never so far seen an increase of the tolerance for carbohydrates in these milder cases follow a starvation cure; in fact, as a rule, I have found the tolerance reduced.

Alarming degrees of excretion of acetone bodies are apt to supervene in this type during starvation, or to follow the resumption of carbohydrate feeding. True, under the management of an expert and in properly equipped hospitals, these symptoms can as a rule be controlled; but, uncontrolled, in cases handled by routine outside, they are liable to become dangerous.

In very severe cases of acute onset, and in fulminating diabetes in children and adolescents, the method is of use as an emergency measure, the sugar often disappearing with startling rapidity, as rapidly as it generally disappears under a properly conducted oatmeal treatment. I regret to report that I have not, however, witnessed more favorable permanent results after starvation than after oatmeal, and the treatment is decidedly more uncomfortable, both to the patient and to the physician.

In view of the fact that starvation is generally employed outside of institutions and under the management of general practitioners who have neither the time nor the facilities, nor possibly the technical training, to control by daily chemical tests the effect of this strenuous method on the general metabolism of the patients, any clinical sign that is easy of recognition should be of value, especially if it constitutes a warning signal of impending danger from continuation of the routine.

Such a sign is edema occurring in the course of a starvation treatment, a sign that I have had occasion to observe frequently, that I have learned to regard with considerable trepidation, and that I do not find mentioned in the literature, the only reference to it that has come to my notice being a verbal acknowledgment of its occurrence by Woodyatt in the course of a discussion of starvation before the Chicago Society of Internal Medicine. Its occurrence in the course of oatmeal cures is mentioned by von Noorden.

Edema usually occurs suddenly, and is associated with an increase of excretion of the acetone bodies, a reduction in urination, and either a cessation of the weight reduction or even an increase in the weight, despite the withholding of food. On the administration of even small amounts of carbohydrate, the edema rapidly disappears, and diuresis is promptly increased without, however, a degree of glycosuria corresponding to the increased urination.

In diabetics, generally, fed on carbohydrates up to or slightly below their tolerance, that is, in diabetics kept free from hyperglycemia and glycosuria, edema is very rare; in fact, diabetics suffering from complicating cardiac or renal lesions in which one would expect edema are generally conspicuously free from the latter.

In hunger, on the other hand, even in nondiabetic subjects, the urinary output generally is below normal in comparison to the liquid intake; hence starving patients not infrequently show no loss of weight for prolonged periods, and occasionally even gain weight. This, of course, can be due only to water retention, and is probably attributable to the retention of the water generated in starvation from the increased forced metabolism of the protein and fats, and from the liberation of water from the shrinking body tissues. No doubt the organism retains this water to maintain a degree of osmotic equilibrium compatible with cell life.

Edema, or its concomitant phenomenon, gain of weight, despite complete withdrawal of food and reduction of liquids, is a starvation phenomenon indicating forced catabolism of body tissues beyond the limits of safety; a degree of tissue destruction that constitutes the main element of danger in the severe types of diabetics, that rarely occurs spontaneously in the milder types of the disorder, and that a rational therapeutist should attempt by all means to prevent and to counteract.

"Pancreatic rest," postulated by Allen, is certainly not favored under these conditions; for nothing presumably can impose a greater strain on the hypothetic internal function of the pancreas than the disassimilation of products derived from forced tissue catabolism.

Edema occurring in starvation cures is a sign, therefore, to resume feeding; it is a danger signal that, if neglected, and especially if associated with nausea, severe headache and tremors, in my experience, invariably either leads to most alarming coma or, if this is prevented by large doses of sodium bicarbonate, leaves the patient, as far as his tolerance is concerned, in much worse condition than before the starvation plan was inaugurated.

Edema during "starvation" can be prevented by the administration of pancreatized oatmeal-alcohol-glycerin clysmata; I have found that they do *not* interfere with the rapid sugar reduction, that they prevent the enormous formation of acetone bodies and materially contribute to the comfort of the patient.

25 East Washington Street.

Lister and Vivisection.—Lister carried out his experiments at abattoirs and in his own home on various animals either after they were dead or when they were chloroformed, or, in the case of the frog, when it had been deprived of sensation by being "pithed." Sheep, horses, oxen, rabbits, cats, bats and frogs were the subjects of his experiments, but not in any great numbers as the somewhat formidable catalogue seems to show. Of the edible animals far more were killed during his lifetime for his consumption than by his experiments, and in the former case by men much less gentle in their feelings for animals than he. Without these experiments he would never have been led to his discoveries. Vivisection, he averred before the Royal Commission on vivisection which sat in 1876, had been essential to him.—Wrench, G. T.: Lord Lister, His Life and Work.

HAS THE NEW-BORN CHILD WITH SUTURED CORD A BETTER START IN LIFE?*

GEORGE RENDLEMAN, M.D.
Senior Physician, City Hospital
AND
FRED J. TAUSSIG, M.D.
Visiting Gynecologist, City Hospital
ST. LOUIS

This report is based on the study of 450 babies born at the City Hospital between March, 1916, and April, 1917. In half of these babies the cord was amputated by the suture ligature method of Dickinson; in the other half, the cord was ligated with two tape ligatures, one of which was placed near the skin margin of the umbilicus. No antiseptics were used in either case except a single application of alcohol to the skin margin in the amputated cases. Dry sterile gauze was placed over the umbilicus and left unchanged until the suture was removed or the cord came off, unless the dressing was accidently soiled. All the babies were cared for by the intern staff of the hospital, supervised in a general way by the senior physician in the obstetric division. The nursing care and records were in charge of Miss Pommel, who has been head nurse of the obstetric division for a number of years. We omitted from both series of cases all premature babies weighing less than 2,000 gm., all operative deliveries and all babies having a serious pathologic condition not associated with umbilical wound healing. In this way we dealt only with normal babies, and eliminated as nearly as possible all differences between the two series, except the manner of treating the umbilical cord. After we had tabulated the results in about 200 cases of each series, we found that additional cases made practically no change in the course of the weight curves, temperature percentages, etc., in the two series, as the mere multiplication of the same experiment could not materially have changed results.

The figure of eight suture[1] was placed 2 mm. within the skin margin of the umbilicus, sweeping around to avoid puncturing the vessels. A moderately fine silk was used for suture material and the suture, if not found clinging to the gauze on the third or fourth day, was cut and removed. In a few instances, through neglect, the suture was not taken out until the seventh or eighth day; there were, however, no apparent untoward symptoms. We have no doubt that the results with the suture method would have been somewhat improved if done only by the resident in charge of the obstetric department. This, however, was impracticable, and would have defeated the main purpose of this inquiry, which was to determine whether or not this method was sufficiently simple to be embodied as part of the hospital routine.

Our personal impressions of the Dickinson suture were favorable. Beyond an occasional slight temporary oozing from the skin stitch there were no complications. A single case of moderate bleeding after six hours occurred in a baby on whom the intern had taken the stitch at the margin of the skin instead of through the skin cuff itself. This was clearly due to faulty technic and not to the method itself. On the other hand, with the ligation method we had moderate hemorrhage in two instances, requiring secondary ligation.

---

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

[1] For a detailed description of the suture ligature method of Dickinson, we would refer the reader to the Transactions of the American Gynecological Society of 1916.

Since the majority of the mothers left the hospital from the eleventh to the fourteenth day and could not readily be followed up, we have but little to say regarding the effect of the suture method on the prevention of umbilical hernia. It is difficult to see how such hernias can be prevented unless the entire skin cuff is removed and the suture made to include the abdominal fascia. This must of necessity be a dangerous and unwarrantable procedure. The only case of umbilical hernia that occurred as far as we could ascertain among this series of 450 babies was in a child whose cord had been amputated by the Dickinson suture. The hernia occurred one month after birth, and was about the size of a twenty-five cent piece.

No deaths from infection of the umbilicus occurred in either group. In fact, under modern conditions in a well-regulated maternity institution, such a death rate can practically be eliminated by due asepsis, irrespective of the special technic employed in handling the cord. Minor infections, however, are still to be reckoned with, and we should not be satisfied until we have, as Adair puts it, "reduced them to an irreducible minimum." Adair's interesting bacteriologic studies of the umbilicus at birth are deserving of amplification and corroboration. According to him, the presence of pathogenic germs does not predispose to infection of the umbilicus. We think the question may fairly be raised whether the child at birth does not possess an inherited immunity against infection by organisms whose habitat is the mother's vulva or vagina. The real danger of infection arises from the hands of the accoucheur or nurse and the instruments and dressings used in the care of the umbilicus. This might very well explain the apparent inconsistency in Adair's bacteriologic findings.

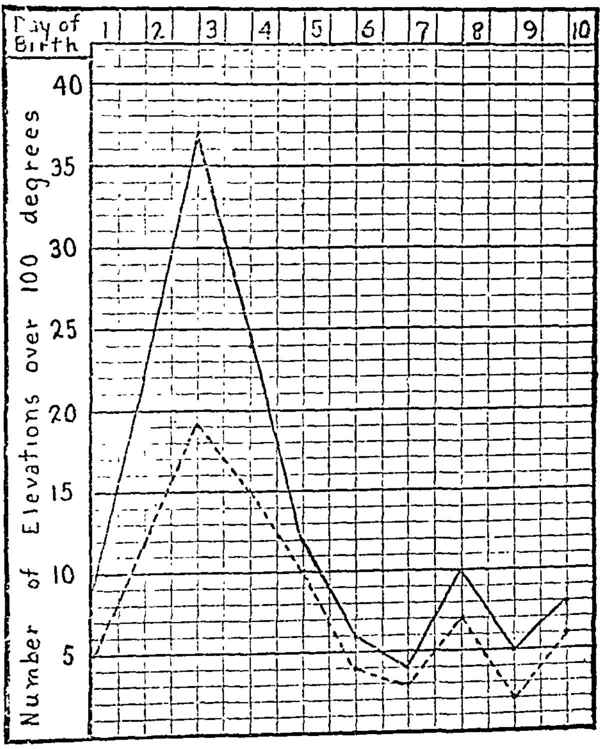

Chart 1.—Temperature elevations over 100 F.: solid line, sutured patients; broken line, ligated patients.

The most striking difference in our two series relates to temperature conditions. Of course we realize that there are other causes for a slight fever in the first ten days besides an umbilical infection, but these other causes should have been equally distributed in the two series, so that a marked difference between the two certainly has significance. We found that in the 225 sutured babies, eighty-five, or 37.7 per cent., developed at some time within the first ten days a temperature of 100 F. or more, whereas the ligated babies showed only fifty-one, or 22.7 per cent., with fever of 100 F. or more. The latter figures correspond exactly with Adair's results in 186 ligated cases with temperature elevations of 100+ F. in forty-two, or 22.58 per cent. When analyzed according to the days after birth we found the interesting comparison given in Table 1.

TABLE 1.—TEMPERATURE CONDITIONS

Day	Sutured Patients		Ligated Patients	
	Over 99 F.	Over 100 F.	Over 99 F.	Over 100 F.
First	33	9	15	5
Second	56	22	38	12
Third	63	37	38	19
Fourth	50	24	42	15
Fifth	27	12	26	10
Sixth	27	6	11	4
Seventh	27	4	18	3
Eighth	30	10	30	7
Ninth	30	5	27	2
Tenth	41	8	29	6

In both series the highest number of temperature elevations was recorded on the third and fourth days, and these were decidedly more frequent among the sutured patients. When, therefore, the suture method is applied by the average intern in the hospital, there is a somewhat greater likelihood of mild infections resulting therefrom than when simple ligation is employed. Doubtless this depends largely on the fact referred to by both Cullen and Dickinson that the cord has no capillaries, while the skin penetrated by the suture does possess such capillaries capable of absorbing infectious material. That these infections were not of serious consequence is seen by the fact that the average loss of body weight from the first to the tenth day in the eighty-five febrile sutured cases was 75 gm., whereas the average loss of the whole series of 225 was 68 gm.

As to disturbance of wound healing as evidenced by a watery odorous discharge, granulomas or prolonged attachment of the cord, we find distinct advantages in favor of the suture method. In twenty-seven instances of the suture method there was a slight tinge of bloody discharge from the umbilicus between the seventh and eleventh days, but never any odorous or free discharge. In the series of ligated babies, thirty-eight presented a bloody or moist discharge between the seventh and eleventh days. This discharge was much more pronounced than in the sutured babies. In five patients there was redness and odor as a result of umbilical necrosis and infection. Four developed granulomas that bled up to the thirteenth day. In forty instances the cord did not come off until between the tenth and thirteenth days. In one of these the baby left the hospital on the eleventh day with the cord still attached. The average length of time elapsing after birth until the separation of the cord was seven and seven-tenth days, which is about what Adair found in his series. Thus in about one third of the patients ligated we have an incompletely healed umbilicus at about the ninth or tenth day, at a time when in most boy babies we would naturally wish to proceed with a circumcision. We think it cannot be gainsaid that the rapid and complete healing of the umbilical wound by the suture method is a distinct advantage in those cases in which a circumcision is contemplated.

The most important index, however, of the effect of the suture method on the general well-being of the child is the weight curve. In this connection we have thought it worth while not merely to figure out the maximum weight loss of the child, as Adair and other writers have done, but, at the expense of considerable time, actually to plot out in these two series of 225 cases the weight curves for the first ten days. This shows some interesting results, as seen in Chart 2. The average initial weight of the sutured babies was slightly in excess of the ligated babies. The initial drop for the first three days was greater in the sutured babies and persisted for one day longer. From the sixth day on, however, the tables were turned and the sutured babies began to gain more rapidly than the ligated ones. The actual figures were those given in Table 2.

The interpretation of these variations that naturally suggests itself is that the sutured babies are to a certain degree unfavorably affected during the first four or five days as a result of the surgical removal of the cord, but that when at the end of that time the umbilicus has fully healed, these children gain more rapidly than the babies with ligated cord. Unfortunately a considerable percentage of mothers were compelled to leave the hospital after ten days, so that records were incomplete for the following days. While it is unsafe to rely solely on impressions, we believe that the gain of the sutured over the ligated babies from the sixth to the tenth days persisted during the following week. In other words, although suturing the cord at the outset is an increased tax on the strength of the newborn child, after the immediate effects are worn off the more rapid wound healing of the sutured navel brings about a gain in weight proportionately greater than in the child with ligated cord.

TABLE 2.—WEIGHT CURVES

Day	Ligated Cord		Sutured Cord	
	Weight, Gm.	Change	Weight, Gm.	Change
First.......	3,204	.....	3,165	.....
Second.....	3,079	—125	3,038	—127
Third......	2,987	— 92	2,960	— 78
Fourth.....	2,980	— 7	2,979	+ 19
Fifth......	3,004	+ 24	3,014	+ 35
Sixth......	3,036	+ 32	3,049	+ 35
Seventh....	3,073	+ 37	3,074	+ 25
Eighth.....	3,102	+ 29	3,094	+ 20
Ninth......	3,107	+ 5	3,108	+ 14
Tenth......	3,136	+ 29	3,124	+ 16

No discussion of the suture method is complete without considering the important saving in the time and responsibility of the nurse in charge. Dickinson speaks of the enthusiasm of the nurses in the maternity division for this method. Our experience was similar. Miss Pommel and her associates at the City Hospital repeatedly expressed their delight over the simplified nursing under this method of handling the cord. Many hours can be saved thereby in the course of each month, hours that can be better employed in other ways, for the care of the mother and the child.

SUMMARY

1. We believe that the suture-ligature method will not greatly decrease the number of umbilical infections. The essential thing is asepsis; and if that is lacking, whether the cord is amputated or ligated is of secondary importance.

2. Umbilical hernias cannot be prevented by this method.

3. The greater immediate loss of weight and greater frequency of slight elevations of temperature after suturing emphasizes the initial shock and the necessity of restricting this method to maternity divisions under the direction of persons of obstetric experience.

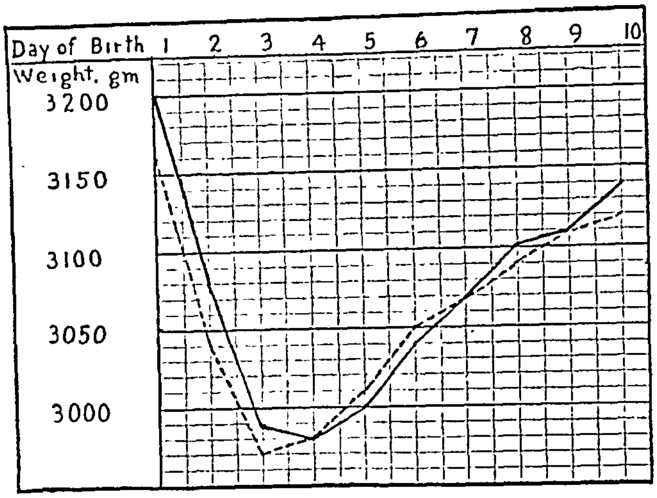

Chart 2.—Weight curve: solid line, sutured patients; broken line, ligated patients.

4. The more rapid gain of the sutured baby after the fifth day shows that the slow healing of the umbilical wound by the ligation method is to some degree a drain on the well-being of the child.

5. The time saved by the nurses when the cord is amputated is considerable, and is of economic importance in the management of hospitals.

6. We therefore urge the adoption of the Dickinson method of treating the cord in all maternity institutions under due precautions. We could find no valid objections to its use; on the contrary, it has certain definite advantages which, though not great, should make it the preferred technic in the treatment of the cord at birth.

ABSTRACT OF DISCUSSION

Dr. George M. Boyd, Philadelphia: Dr. Dickinson's method of ligation of the cord has, undoubtedly, certain advantages. The essayist has shown us, however, that in a certain proportion of cases infection followed. He also shows by his chart that there was a greater elevation of temperature in the first week of the puerperium. We have, therefore, these two factors to consider — the greater elevation of temperature, and the fact that the method will not eliminate infection to as great a degree as I had hoped when I first read Dr. Dickinson's paper.

Obstetric work is emergency work, to a certain degree, and it will always be. While, in the hands of those who are practicing obstetrics as a specialty, this method of treatment of the cord may be carried out in many cases to advantage, since the length of labor, time of delivery, and the presence of the obstetrician are uncertain, the older method of ligation, I think, must still be taught. I should feel, then, that while this method has certain advantages, the older method must still have a field of usefulness.

Dr. Charles S. Bacon, Chicago: I have not practiced this method, but have for a number of years tied the cord right at the junction of the skin and have found that very satisfactory. It obviates the difficulties that are encountered when the cord is tied half an inch or more away from the skin. There is practically no more trouble in the dressing of the cord thus tied than if the cord were not there. The only thing I do is to pour alcohol over the site at the regular dressing of the baby. I have seen no trouble at all. Therefore, the advantage mentioned by Dr. Taussig in the economy of the dressing would not apply to the cases as I manage them.

Dr. Asa B. Davis, New York: I have not practiced this method of suturing the umbilical stump. In our hospital service we ligate the cord about 1 inch from the abdominal wall. Dr. Taussig calls attention to the fact that infants do not gain until the umbilicus ceases to granulate and is well started towards healing. We can confirm this by many cases of minor degree, and also in a few exaggerated cases of the so-called "carneous stump," sometimes from one-half to three-quarters of an inch above the level of the abdominal wall. A tedious process of healing follows, aided by cutting away granulations with silver nitrate. During this time the infant is either at a standstill or retrograding. I believe that a very large percentage of digestive troubles, green stools, fever, and jaundice in infants during the first ten days is due to some grade of infection at the umbilicus. This method of treating the umbilicus may be valuable in the hands of trained surgeons in obstetric hospital service. Its general use, sometimes by unskilled and not surgically clean operators, must lead to many fatal results.

Dr. F. J. Taussig, St. Louis: I feel that the method is not one which will become popular. It must be limited largely to maternity institutions under the guidance of expert hands. In such institutions I believe it has considerable value as a time saving procedure, and in limiting those rare but serious epidemic infections that occasionally prevail in all maternities.

THE REPAIR OF CLEFT PALATE

A TECHNIC AND THE REASONS FOR IT *

HARRY M. SHERMAN, M.D.
Fellow of the American College of Surgeons
SAN FRANCISCO

Cleft palate, a pure deformity, has no pathology. Its incidence and the part heredity plays in its production have long been studied by Mr. William F. Blades of the Eugenics Record Office, but no deductions can be drawn from the data as yet collected; so we must pass by this interesting phase of the condition, as well as its anatomic complex.

The description of a method for the repair of a cleft palate will be limited to the single sided complete cleft. This is the most common lesion. All technical details applied to it are also applicable to other varieties of the deformity without special indication.

The time at which to operate is of initial importance. I wait until the child has passed the first three or four months of life and has established a satisfactory state of health. I advocate and practice operating before the eruption of any teeth. The infant's mouth at this time is not a too septic place, and sepsis is the greatest obstacle with which we have to contend. This is, of course, long before the incidence of infection of the tonsils or of the pharyngeal adenoid tissue, and also long before the child learns to speak or to attempt any imitation of the voice sounds he hears. It results that we come to the beginning of the work when the child weighs about 15 pounds.

The first step is to narrow the cleft by elastic compression. Commonly the halves of the uvula may be seen to be close together or even touching, separating, however, when the child opens the mouth, in front and at the back, to cry. The widest part of the cleft is at the front, and the intermaxillary bone projects well in advance of the maxilla on the opposite side of the cleft (Fig. 2). I deprecate measures which perforate the maxillae for the passage of wires to draw the bones together, chiefly because of the possible interference with budding teeth, and the danger of a sequent sepsis. It is possible to draw the bones materially together — so as to make the intermaxillary overlap the maxilla — by elastic band traction, pulling on hooks of the hook and eye variety, fastened in adhesive plaster which is stuck on the child's cheeks (Fig. 1). When the child is quiet, the elastic is steadily drawing the bones together, and its effect is much enhanced when the child laughs or cries. The anterior and middle parts of the cleft are definitely narrowed by this means, as can be seen in the improvement in the appearance of the nose, the flattened nostril and tense ala being deepened and relaxed. As soon as the ends of the broken alveolar arch overlap, the child is ready for the operation on the sofe palate.

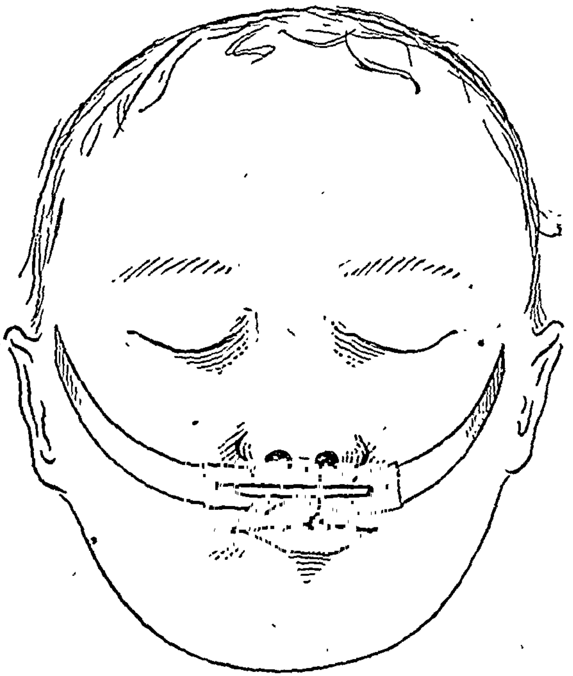

Fig. 1.—Detail of adhesive plaster and hook and elastic compression of the maxillae narrowing the cleft. Note that the inner end of the plaster is put on the cheek outside of the side of the nose and that the posterior end runs up as high as the top of the ear.

All operators today are practically using the Langenbeck or the Lane method of closing the soft palate. The former, recognizing that the cleft represents a failure of union, attempts to correct that fault by putting the parts in union with the least disturbance of tissues. The Lane method splits the velum between its pharyngeal and buccal sides, and turns flaps over from one side to the other. This necessarily jeopardizes the palatal muscles in the splitting, and results in extensive scarring in healing.

The Langenbeck method can be so done as to disturb the muscles individually not at all, though they are, as a group, moved toward the middle line. The statement that the Langenbeck method is inadequate in a wide cleft with a flat palatal arch does not apply to the velum; therefore the Langenbeck is the method I use.

Now, instead of paring the sides of the cleft to get raw surfaces for union, I split them from the attachment of the velum to the tips of the uvular halves. I now suture the posterior edges of the split uvular

---

* Read before the Section on Surgery, General and Abdominal, at the Sixty-Eighth Annual Session of the American Medical Association, New York, June, 1917.

halves together, tying the knots in the pharynx (Fig. 2), and follow by uniting the anterior edges, tying the knots in the mouth (Fig. 3). By this plan I avoid sacrificing any tissue, and if secondary or other sutures are needed, I have all of the original tissue up to the very end. Again, I get broader surfaces of contact for union, though this seems, in failing cases, to be a matter of doubtful value. Finally, I can plan the sutures so as to avoid strangulation of any part of the uvula; and this is a matter of importance, for a shrunken uvula materially limits the palate's usefulness in phonation and deglutition. The plan of splitting the uvula and velum I think originated with the late Hugh Alexander Ferguson of Chicago.

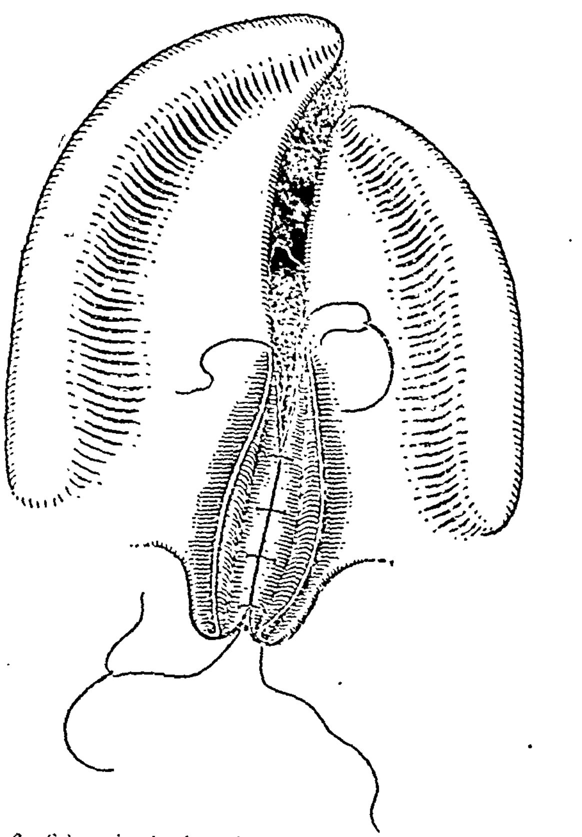

Fig. 2.—Schematic showing of the projection of the intermaxillary bone beyond the maxilla. The margins of the soft palate have been split along their contiguous edges. The posterior flaps are drawn together by sutures which are tied on their pharyngeal surface.

This double pharyngeal and buccal suture line is necessarily stopped at the edge of the hard palate; anterior to that point I use only a buccal suture, and I mattress it. By this means I turn down the edge of each side into the mouth, get broader surfaces of contact for union, and thicker tissue after healing where formerly it was too thin (Fig. 3). I do not attempt to come farther forward by this plan than half the length of the hard palate. This leaves me plenty of tissue in front for the blood supply. I make, on each side, lateral incisions, keeping them outside the posterior palatine foramina and carrying the posterior ends well back. This lets me lift up the whole of the soft palate and move it toward the middle, and to do the same with the mucoperiosteum of the posterior half of the hard palate (Fig. 3). Now around these two flaps, mobilized and approximated and sutured, I pass a piece of ordinary tape, saturated in Moorhof-Mosetig bone wax. This is caught by a stitch, at both the front and the back, on each side, and is so sutured that it acts as a relaxation suture; as it is somewhat stiff, it is also a sort of splint, and immobilizes the soft tissues involved (Fig. 4). The part where my repaired palates begin to break down is at the junction of the hard and the soft palates. Here the strain seems to be greatest or the circulation poorest. In the bight of my tape the flaps cannot pull apart, the mattress sutures are not torn out, and union must occur. Finally, for purposes of cleanliness, I pack the lateral incisions with iodoform gauze.

The tape is left undisturbed for from ten or twelve to fourteen days; the gauze packings are changed daily until the incisions heal so much that they will not hold the gauze.

Union now gives us a palate with a somewhat shortened uvula, and this is usually destined to become still shorter as contraction of the scar tissue occurs. I have never seen a normally long velum after the operation, but I have seen them very nearly normally long, and with an active musculature, showing that I had not spoiled the nerve supply.

During this period the cheeks and the maxillae are held by the elastic traction. and I now repair the lip so that it shall remodel the alveolar processes and make an approximately normal alveolar arch. I shall not impose on any one the way in which I repair the lip. It is something in accordance with a method I once saw practiced by Charles H. Mayo. Each man must find out the way in which he can do this dainty bit of work best, and follow that way.

In the front of the mouth the mucosa is tightly applied to the bone, and the material for any sliding plastic is lacking. Here is, however, a perfect place for a Lane flap, not made so big as to open and ruin tooth follicles, but broad enough to bridge the cleft

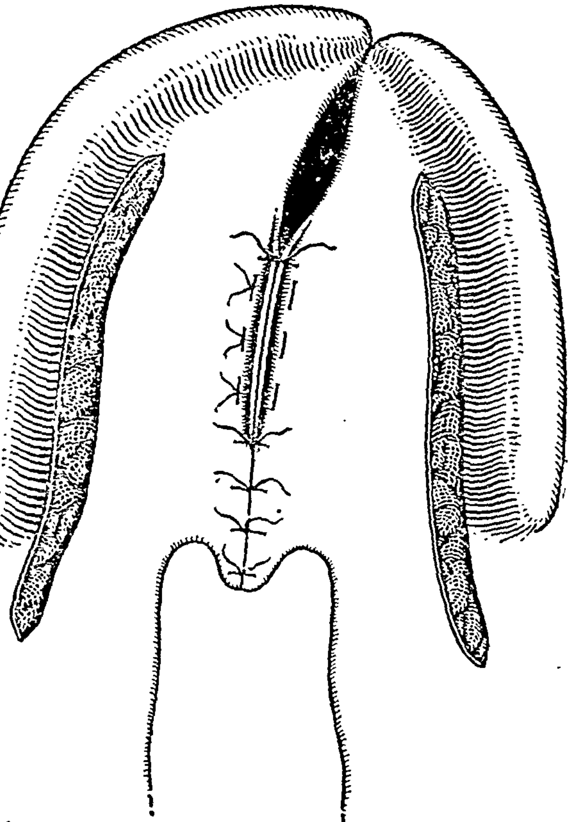

Fig. 3.—The anterior flaps of the split soft palate and uvula have been sutured in the mouth. The mucoperiosteum of the posterior half of the hard palate has been mobilized by the lateral incision and by being separated from the bone, and the edges united by mattress sutures closing the cleft. The lateral incisions are stuffed with iodoform gauze.

and long enough to close the whole length of the cleft left open. I take the flap from the wider side and pocket it under the mucosa of the narrower side. It is quite competent to do this to just behind the teeth and to leave no opening, a condition which is most annoying, as it readily permits leakage of fluid into the nose (Figs. 5 and 6).

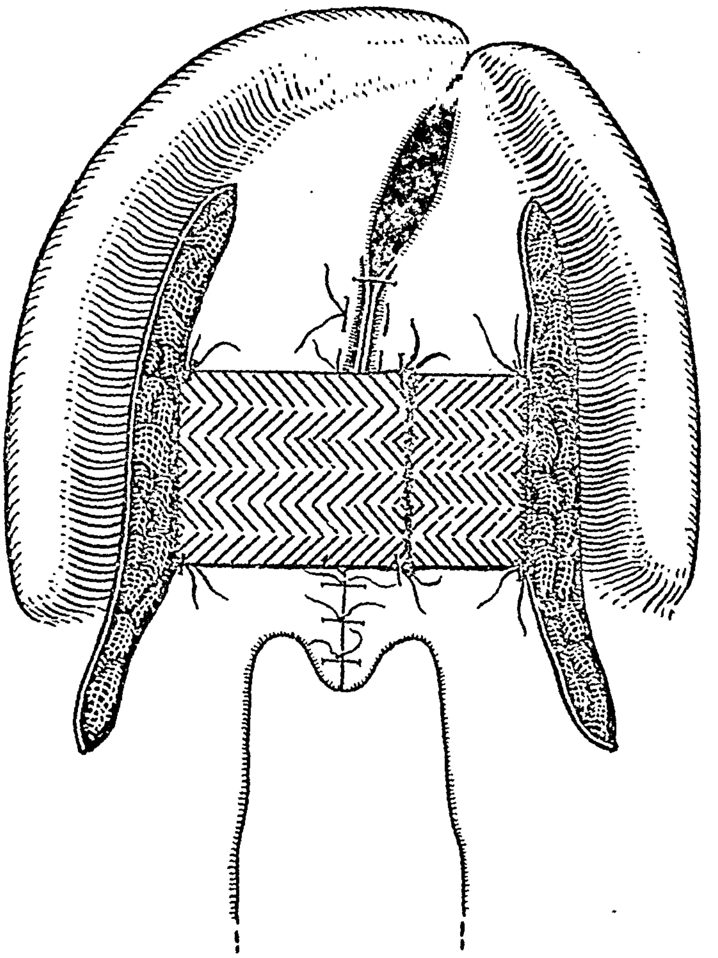

Fig. 4.—The waxed tape in position stitched where the ends meet, so as to maintain a proper tension, and caught by a stitch on each side, in front and at the back to keep it from rolling up into a string. The bone wax stiffens it and prevents its becoming saturated with saliva.

The suture material is of moment. In the uvula I use fine twenty day chromic catgut or horsehair or fine waxed black silk. The wax really is Moorhof-Mosetig bone wax, and the silk is boiled in it. Horsehair and silk have the disadvantage of usually having to be removed, though they may tear out of their light hold on the uvular mucosa. In the velum and in front of it I use black waxed silk or fine silkworm gut. This is for the sutures that are mattressed, and it is good policy to leave a long end to facilitate picking it up when the suture is removed. In the front part, for the tacking into its pocket of the Lane flap, the chromic catgut is enough.

I have used the body weight of 15 pounds as an index as to when the child is ready for the operation. Frequently these children are undernourished because they have difficulty in sucking a nipple on a breast or a bottle. So I have them all fed by a catheter in the nose. In a short time a child will learn to acquiesce in the method, and we can be sure that it really is getting a proper amount of food and without undue effort. After the operation, when the palate is freshly sutured, it is a definite advantage to eliminate the muscular act of swallowing and the consequent strain on the sutures in the soft palate. By this method it is quite possible to keep the child gaining in weight through the whole of the operative phase.

In operations on these children the anesthesia is ether, and the ether vapor is blown in through a soft rubber catheter which is fastened by a stitch in the nose, the stitch passing through the septum. The end of the catheter must reach only to the posterior nares. The child's head hangs half over the edge of the table, and is supported by a little shelf. I use a large complex gag, which holds the mouth open, holds the tongue forward, and pulls the corners of the mouth outward. Around the whole operative field I have black or dark blue cloths, sheets, towels, gowns, etc., to obviate the glare of the ordinary white environment. By this means the mouth is in the high light, rather than in the shadow.

350 Post Street.

ABSTRACT OF DISCUSSION

Dr. Vilray P. Blair, St. Louis: The Brophy operation was used fifty years ago by an Australian. The Lane is but an enlargement of the Cawley flaps and the Davis could be called a Warren with equal justice. The relationship of various technical steps to each other and to the age of the patient are much more important than the choice of the technical steps themselves. Dr. Sherman has brought out a new and useful technical step. In almost every step of his work and mine we differ radically and I would not have the idea that one technic was any better than the other. As to the matter of age, I am firmly intrenched with those who believe the earlier an operation is done the better. The best time for the closure of the lip is the first twenty-four hours, on account of the feeling of the parents; the second reason for early operation is the ease with which the bones are molded into place; and, thirdly, at this age shock is not a consideration. As to the soft palate, I use the straight Langenbeck operation. If one will wait until the child is 14 months old one can close the whole palate with ease in two operations. There is just enough tissue at birth to close the

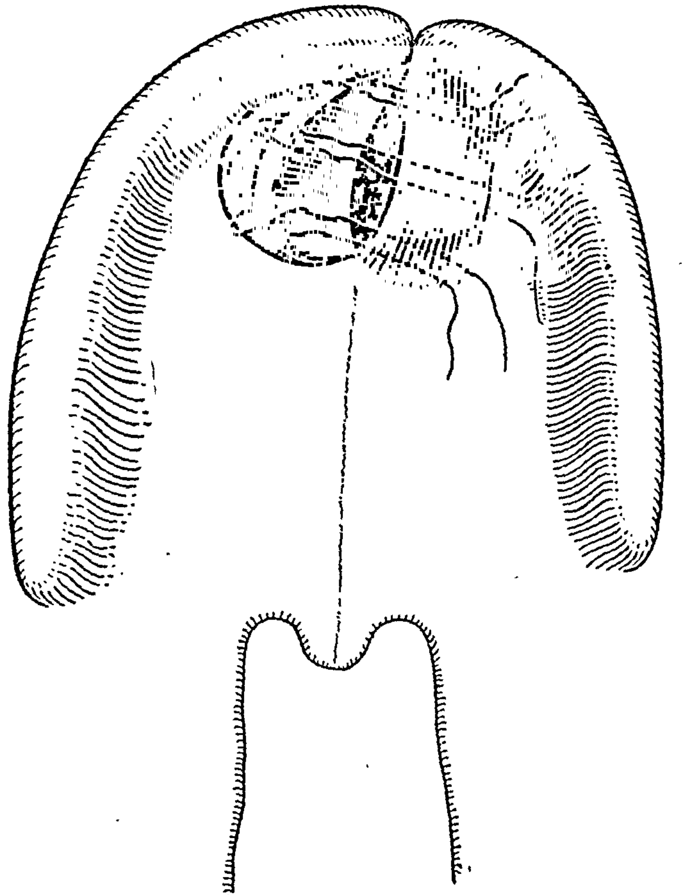

Fig. 5.—The little Lane flap partly turned up, the pocket on the opposite side made ready, and the suture to draw the flap into the pocket placed. The elastic traction and the repaired lip have remodeled the alveolar arch into a normal shape.

palate. After a year we have 39 mm. to close 38 mm. and a space. We must accommodate the methods to the age in this work. In all of these cases there is a considerable spreading of the nostril which will necessitate an operation on the floor of the nose to round it up as on the other side, but where the cleft remains wide open for a long time, for perfect closure of the lip there must be an operation to restore the nostril. The Brophy operation is usually not practical after three months. Some cases may be closed by elastic traction of a rubber band. There is no end of tricks that one must resort to in this work.

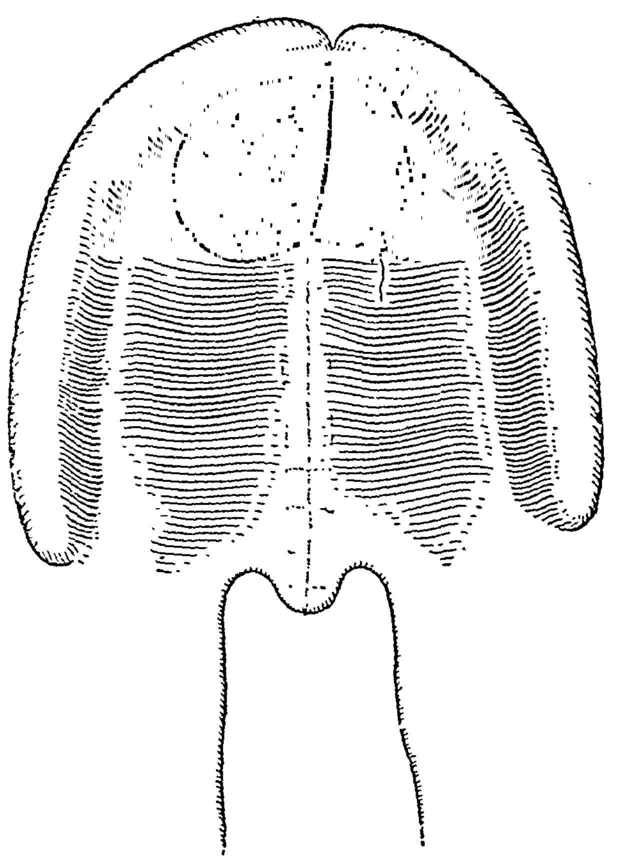

Fig. 6.—The flap drawn into place and held.

Dr. Truman W. Brophy, Chicago: There are fifteen different congenital defects of the palate, treatment of which requires methods of procedure sometimes slightly and sometimes radically different from all the others. The *premaxillary* bones are sometimes absent. In that case the fissure is almost invariably in the central line and the nasal bones are deficient.

Having operated on about 4,000 patients with cleft palate, I am convinced that when the alveolar processes are not cleft the operation should be deferred until the patient is between 12 and 14 months old; and that when the alveolar processes are cleft, as well as the whole hard palate, the patient should be operated on in early infancy, before the *fifth month.*

In complete cleft palate what is accomplished by first closing the lip? The greater deformity is concealed but the cleft is not closed as it should be. By drawing the lip together the anterior part of the hard palate is approximated, but not the enormous breadth of the tuberosities of the jaw. Had the bones been approximated in infancy, the patient would have a normal arch, but this is abnormal. The bones should be put together and fixed so they will unite. To do this the intervening soft parts and compact bone should be removed, the cancellated bone exposed so it will meet cancellated bone and thus be approximated and held quiet until the bones firmly unite. That is the essential thing to do. If there is any better method to pursue than the one I have devised, then let it be made known. A complete cleft palate is not unlike a fracture of bone, separated sutures, or an ununited fracture. I have never done a Langenbeck operation and I never will, for the reason that the Langenbeck operation calls for lateral incisions in the soft parts.

Dr. Walter B. Swift, Boston: I want to emphasize one point omitted in cleft palate treatment. It is the after-treatment. The majority of these patients have some speech disorder which persists long after the operation. The chief object of that operation should be the perfection of speech. In the Massachusetts General Hospital we have, in our speech clinic, evolved a system for the perfection of speech in these cases. Several now possess perfect speech.

Dr. Harry M. Sherman, San Francisco: It is a question as to whether the lip should be operated on early or late. When you put in a needle, little or big, and touch the tooth germ you have penetrated the capsule, and by moving the needle around to find a way between the teeth you inevitably make a relatively big hole. I shall never attain the skill which will enable me to pass between these closely packed-in tooth follicles and pull a wire through without wounding and infecting the follicles.

As regards the tensor palati muscles, I make the incision outside the hamular process and so do not cut them off. I move all of the tissue implicated inwards, and that must stretch the nerves which supply the muscles but may not tear them off, because two or three years later in life I have seen these palates move. Dr. Charles H. Mayo used to put a piece of gauze round the mucoperiosteal flaps as a drain. I use tape instead of gauze, and wax it so that it cannot soak up saliva and perpetuate septic infection in the mouth, and then adjust it to be a relaxation suture. That is my innovation.

Of course training these children to speak is a very important matter. It is especially important in those families in which bad English and bad enunciation are the habit. In families in which good English and good enunciation are the habit, children will speak very well without much special instruction, though they will speak better if they have it.

PREMATURE DETACHMENT OF PLACENTA, WITH DELIVERY OF A LIVE BABY BY CESAREAN SECTION

David S. Hillis, M.D., Chicago
Attending Obstetrician, Cook County and Provident Hospitals; Assistant Obstetrician, Chicago Lying-In Hospital; Instructor of Obstetrics, Northwestern University Medical School

Mrs. S. G., aged 35, primipara, was in the ninth month of pregnancy. For the past thirty days there had been a small amount of albumin with no casts in the urine. The maximum blood pressure was 120. May 12, the patient was struck in the abdomen by the head of a 3-year-old child, who threw himself in her lap. This caused considerable pain at the time, but was soon forgotten by the patient. May 16, four days later, the patient walked seven blocks; when near her house she was taken with moderately severe pain in the lower abdomen and back, which was continuous, not intermittent. One hour later, fresh blood was discharged from the vagina, in small quantities but continuously. The patient thought that she lost about 4 ounces of blood during the first hour or two. At 3 p. m. (three hours after the pain had started), examination at the Chicago Lying-In Hospital showed: General condition of patient excellent; no signs of shock; pulse 94; color good; fundus one finger below ensiform; uterus tense with increased tenseness at intervals of about two to six minutes, accompanied by pain. Pain, however, was constant in lower abdomen and back. Fetal parts were difficult to outline on account of tenseness of uterus, but back seemed to be to the left, head movable, floating above inlet. Fetal heart tones were 140 to 148 left lower quadrant, regular, rhythmic, but somewhat variable during a minute's observation.

Rectal examination showed cervix not effaced, about 3 to 4 cm. long. The os hardly admitted one finger. During this examination about one-half ounce of very dark colored semifluid blood was expressed from the vagina. At 4 p. m.

the heart tones went to 176, with slight irregularity; otherwise the condition remained the same. At 5:30 p. m. the heart tones were 164 to 168, and somewhat irregular. There were slight uterine contractions, irregular, at intervals of from three to seven minutes. There was constant pain in the back and the lower part of the uterus. Palpation of the uterus immediately caused a tenseness of the uterine wall, equal to the painful contractions which came on spontaneously; the uterus at all times was firmer than normal, and slight bleeding from the vagina continued, some of which was bright in color. Rectal examination showed no change from the findings at 3 p. m. More thick dark colored blood was expressed from the vagina.

At 6:30 p. m. under ether anesthesia, classical cesarean section was done. The child was not asphyxiated. On removal of the baby, a clot of blood was seen lying in the opening of the uterus, and on introducing the hand to remove the placenta, the clot was expelled on to the abdominal wall. The position of the placenta in the uterus showed that it was not praevia. This clot was in shape a circular biconvex disk, 14 cm. in dameter and 4 cm. thick in its middle or thickest portion. It weighed 15 ounces. The surface and edges were smooth and regular in outline, except in one part of the circumferance, where there was a small clot about 4 cm. in diameter, ragged and somewhat irregular in outline. This was attached to the edge of the main mass. This clot was very firm, dark, almost black, and retained its integrity in spite of much handling for examination, weighing and measuring. The placenta was lying on the posterior wall of the uterus, with its edges near the incision in the uterine wall as the uterus contracted after removal of the baby. The uterus did not contract well after the removal of the placenta, and 1½ ampules of pituitary extract were injected into its wall directly. This caused a fairly satisfactory amount of contraction, but less than is usually secured by the administration in the same manner of 1 c.c. of the drug. During the suture of the muscle walls, it was noticed that the peritoneum over the entire surface of the uterus appeared mottled, which was evidently due to small hemorrhages under the serosa. The uterus had been subjected to only a minimum amount of traumatism and manipulation. This mottled area was seen on the posterior surface, as well as on the sides and anterior surface, those on the anterior wall not being over the placenta site. The uterus now was contracted in a satisfactory manner, and it was decided not to remove it. The macroscopic appearance of the muscle wall in the incision was normal. The placenta was circular in shape, 30 cm. in diameter; the cord was centrally implanted, and the fetal surface showed no abnormalities. The maternal surface did not show a well marked area of depression, corresponding to the size of the clot, although there was a considerable area, irregular in shape, where the placenta was thinner than the rest and somewhat paler.

The diagnosis was based on the history; the sudden onset of the pain; the character of the pain; the marked irritability of the uterine muscle; the abnormal tenseness of the uterus, and the bloody discharge appearing one hour after the onset of the pains; and in spite of the continuance of the heart tones and the absence of signs of shock on the part of the mother, the absence of these two signs was accounted for by the fact that the separation was not of sufficiently large extent to kill the baby or produce shock; although, in these cases shock is usually present out of proportion to the amount of hemorrhage and apparent traumatism. The patient, who was a robust woman, went home with her baby in excellent condition on the fourteenth day.

The case presents several points of interest:

1. The presence of signs and symptoms definite enough to justify a diagnosis before the death of the baby.
2. The hemorrhagic condition of the entire uterine surface corresponding to Williams' idea of the pathology of premature separation.
3. The value of pituitary extract injected directly into the uterine muscle in these cases.

CLINICAL MANIFESTATIONS AND TREATMENT OF GAS POISONING

MILTON MANDEL, M.D., CHICAGO
Major, M. R. C., U. S. Army; Chief of Medical Service, U. S. Base Hospital No. 12
AND
W. STANLEY GIBSON, M.D., CHICAGO
Lieutenant, M. R. C., U. S. Army
FRANCE

The ingenuity of the German mind has long been recognized. During the past three years this ingenuity has made itself felt by devising diabolical schemes for the destruction of life—both combatant and noncombatant. Submarine warfare was expected; liquid fire was a possibility; but poison gas was utterly unknown until used by the Germans during the second battle of Ypres in the spring of 1915. Since then, poison gas has been used by all belligerents with telling effect. Since July 19, 1917, our enemy has used a new preparation which for want of a better name is called "mustard" gas.

The victims of this gas present a clean-cut clinical picture characterized by conjunctivitis with excessive lacrimation, laryngeal and bronchial irritation, and superficial burns. These symptoms are usually preceded by epigastric distress and emesis.

When one is exposed to the gas, an odor not unlike mustard is experienced, followed in a number of hours by the symptoms mentioned. The so-called free interval, rarely less than four hours and practically never more than sixteen, is explained by the fact that this "mustard" gas decomposes on exposure to moisture, the symptoms resulting from the action of the products liberated by the decomposition.

SYMPTOMS

The victim, although knowing that he has been exposed, feels perfectly well and usually continues to "carry on" until relieved from duty. The first evidence of trouble usually occurs hours later, when he may be awakened by epigastric distress and violent vomiting, followed soon afterward by the cardinal symptoms:

1. The conjunctivitis is severe; photophobia is common and lacrimation profuse. Puffiness of the eyelids is constant in the severer cases. Corneal involvement is very rare.

2. The laryngitis and bronchitis are primarily irritative—not inflammatory—and nonfebrile. A sense of constriction about the larynx and tightness of the chest are early and usually persistent symptoms. Aphonia is common but usually evanescent. On the other hand, the cough occurs early and is the last symptom to disappear. It is paroxysmal in character, particularly severe at night, and accompanied by a serious discharge in light cases, hemorrhagic expectoration in the most severe, and purulent in the late cases secondarily infected or complicated by bronchopneumonia.

3. The exposed parts, for example, the face, hands, forearms, and in the Kilties the knees, are most commonly affected by burns; frequently the genitals, buttocks, shoulders and back are severely burned; the feet are but rarely involved. During the first forty-eight hours the skin may be merely pigmented, presenting

a blackish, brown appearance, and harsh to the touch. After a number of days, desquamation takes place. More often, however, there is distinct blistering, the vesicles varying in size from a millet seed to 4 or 5 inches in diameter. The burns usually involve only the superficial layers of the skin, although second degree burns are not uncommon. It is our belief that all the symptoms enumerated above are the result of chemical burns; that the mucosae of the eyes, larynx and bronchi, as well as the skin, are excoriated by the gas.

PHYSICAL EXAMINATION

In addition to the conjunctivitis and skin burns, examination reveals a diffuse bronchitis, usually nonfebrile, with hurried breathing. True dyspnea is rare except in the very severe cases complicated by bronchopneumonia, or when pulmonary edema develops. Occasionally, the heart is enlarged to the right, with an accentuated second pulmonic tone. The blood pressure, systolic and diastolic, is slightly reduced. The blood picture is in no way characteristic. Slight eosinophilia (from 3 to 5 per cent.) has been noted in patients suffering extensive burns.

The course of this syndrome is self limited, and depends entirely on the amount of damage done and the time elapsing between the gassing and the institution of rational therapy. Complications necessarily modify and alter the prognosis. In very severe cases, pulmonary edema may develop early; and death may occur a few hours after the onset of symptoms. On the other hand, in the lighter cases, convalescence is rapid.

COMPLICATIONS

Bronchopneumonia is unquestionably the most common complications with which we have to deal. It usually comes on from seventy-two to ninety-six hours after the exposure to the gas, and frequently runs a turbulent course with high fever, intense dyspnea and cyanosis, cough, and not uncommonly bloody expectoration. The termination is either by lysis in two to three weeks, or fatally in a few days from a superimposed pulmonary edema *which is not of cardiac origin.* Unlike the chlorin gas, this more recent product affects the heart but little. The myocardium, as demonstrated by necropsy, is not damaged. To be sure, at times the heart is enlarged, transversely; but this is purely compensatory, as the pulmonary changes necessarily increase the work of the right ventricle. Albuminuria is not uncommon, but true nephritis has been extremely rare in our experience. This is quite remarkable, as the burns involving skin and mucous membranes are frequently quite extensive.

We regret exceedingly that we cannot discuss prognosis. The cases which have come under our observation included every degree of severity; some of the patients were ready for duty in a few days, while other cases were severe, with and without complications. Also, the number has been sufficiently large to justify very definite conclusions. To publish these conclusions would be unfair to our allies and ourselves, and might be of value to our enemy.

TREATMENT

The intensity of the symptoms depends largely on the rapidity with which treatment can be instituted. We suggest the following procedure, viz.:

1. Knowing that this gas decomposes on exposure to moisture, we consider it highly important that the victims be given an entire change of dry clothes as soon as is practicable, and that dry sleeping quarters, preferably above ground, be procured.
2. Phlebotomy should be performed for the early pulmonary edema which develops in the very severe cases.
3. Oxygen inhalations are of questionable value, but should be tried.
4. The eyes should be irrigated with boric acid solution; alkalis should be used internally, and 10 per cent. sodium bicarbonate solution should be applied externally for cutaneous burns.
5. For the distressing paroxysmal cough opiates are indicated, preferably codein or heroin, in sufficient dosage to allay the irritation of the respiratory mucosa. Antispasmodics, such as belladonna, apparently aggravate the respiratory symptoms, owing to their drying effect.
6. Complications should be treated as they arise.

SUMMARY

1. An interval (from four to sixteen hours) of freedom from distress exists between the actual gassing and the onset of the symptoms.
2. The cardinal symptoms, conjunctivitis, laryngitis, bronchitis and skin burns, are all due to the excoriating effect of the gas.
3. The principal complications are early pulmonary edema and relatively late bronchopneumonia.
4. Dry clothing and sleeping quarters may prevent the development of symptoms after slight exposure, and possibly may lessen the severity in those more severely gassed.

[Editor's Note.—The "mustard gas" from German shells is well known to the Allies in regard to its composition and the steps to be taken to protect against it. The gas is liberated from liquid in the shell; and when the liquid is scattered on the clothing or skin, or when the men move over ground wet with the liquid, burns will result. Protection against the liquid should be care to avoid contact. The liquid is dichlorethylsulphid. As the gas has very little odor, the men may delay in applying their respirators and be gassed or, in order to have better vision, they may neglect to adjust the whole face-piece and suffer a lacrimatory effect. The eye symptoms disappear, and no permanent injury results. The English box respirator is a complete protection to the eyes and lungs against the gas.]

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

ATOPHAN.—A proprietary brand of phenylcinchoninic acid. It complies with the standards for phenylcinchoninic acid, U. S. P., but melts at from 208 - 212 C.

Actions, Uses and Dosage.—See New and Nonofficial Remedies; 1917, p. 239, under Phenylcinchoninic Acid and Phenylcinchoninic Acid Derivatives.

Manufactured by Schering and Glatz, New York. U. S. patent No. 1,075,171 (Oct. 7, 1913; expires 1930). U. S. trademark No. 84,596.

Atophan Tablets.—Each tablet contains atophan 0.5 Gm. (7½ grains) and a small amount of cacao.

INFLUENCE OF THE SEX GLANDS ON DEVELOPMENT

The influence exerted by the genital glands on the other parts of the reproductive apparatus, and on the body generally, is a remarkable illustration of the chemical correlations that may exist in the organism. That the lack of the sex glands—a situation which arises as the result of castration—may bring about conspicuous alterations in physique and modifications of the expected development is a fact long familiar. When the removal of testes or ovaries is carried out early enough, that is, before the period of puberty, the development of the so-called secondary sexual characters is interfered with. We must regard the germ cells, says Starling, not only as representing the cells from which the individuals of the new generation may be developed, but also as concerned in the formation of chemical substances which, discharged into their hosts, affect many or all of the functions of the latter, with the object of finally subordinating the activities of the individual to the preservation and perpetuation of the species.

Even more striking than the long observed failure of development in the absence of suitable hormones furnished by the sex glands, a result that is essentially negative in character, are the positive alterations in bodily evolution that result from the introduction of female factors into the developing male, and vice versa. By means of transplantation experiments, in particular, it has been possible to show that the sexual glands direct an influence on sex characters through something resembling an internal secretion. Remarkable instances have been afforded by Steinach[1] in particular. For example, he transplanted to castrated young male rats and guinea-pigs the ovaries of their sisters; the males became in weight, size, and in all proportions of their body like females. The mammary glands were highly developed and even secreted milk, whereas the growth of the penis was obviously inhibited. On the other hand, young castrated female guinea-pigs increased in weight and size after implantation of testes, and became in all the proportions of their body like males. The castrated male is feminized by the ovary, the castrated female is masculated by the testis. Besides, the feminization and the masculation in the experiments of Steinach were also manifested in the transformation of the sexual behavior of the experimental animals.

It is apparent from this and other evidence which might be cited that the hormone of the sex glands acts in a sex-specific character, as Lipschütz[2] has recently termed it; that is, the male gonad furthers the development only of male sex characters and inhibits the development of female sex characters, whereas the female gonad furthers the development of female sex characters and inhibits the development of male sex characters.

Steinach has gone a step farther in recent years in suggesting that the organism is nonsexual until it has reached a definite stage in embryonic development. The sexual transformation of the body is believed by him not to begin until the puberty gland has become differentiated into male or female. In support of this view, Lipschütz cites the observations that a castrated hen assumes the plumage and the spurs of a cock, whereas it is well known that the castrated cock keeps his plumage and spurs. From these facts, he adds, we must conclude that the development of the male plumage and the spurs does not depend on stimulation by the male sexual gland, whereas the female sexual gland transforms a male-kite plumage into a female one and inhibits the growth of the spurs. The male plumage and spurs become male sex characters, according to Lipschütz' interpretation, not because they result from an action of the male sexual gland on the nonsexual soma, but because the development of these nonsexual characters is influenced in the female by the internal secretion of the female sexual gland. The hormones of the sex gland may thus further or inhibit the natural continuance of conditions foreshadowed in the embryonic form.

THE BANANA AGAIN

Several years ago we called attention to the banana as an undervalued source of nutriment.[3] The defense of this fruit, which ought to be available at comparatively low cost in times of normal commerce and transportation facilities, almost invariably provokes protests from persons who maintain that the banana is a cause of indigestion and a treacherous dietary component which is at best to be looked on as a luxury, harboring insidious dangers to alimentation. Since our earlier comments in which the fallacies of the still current prejudice against the banana were exposed, several investigations, notably those by A. R. Rose and others at the New York Post-Graduate Medical School and Hospital, have served to fortify the wider use of the banana as a wholesome, palatable and nutritious article of food. The latest of these dietary studies[4] has even gone so far as to put beyond criticism the appropriateness of the banana as a food for young children.

[2] Lipschütz, A.: On the Internal Secretion of the Sexual Glands, Jour. Physiol., *1917*, **51**, *283*.

[3] The Undervalued Banana, editorial, The Journal A. M. A., Jan. 27, 1912, p. 276.

What is the banana, from the standpoint of the student of nutrition? It is essentially a highly edible source of carbohydrate comparable, in its richness of foodstuffs, with the most popular of fruits. Like other members of this group of products, the banana undergoes specific changes in the course of its ripening. The nutrient carbohydrates in the banana comprise essentially one fifth of the entire fruit. In the green specimens this carbohydrate is in the form of a starch, but on maturing this is converted first into sucrose and finally into invert sugar. The proteins amount to less than 1 per cent., and their nature is at present unknown. The fat and fiber are negligible. The ash is important both in amount and in the kind of its constituents. Looked at simply as a source of food fuel or energy, the banana yields over 400 calories per pound. Olives, sweet potatoes and corn are the only common fresh fruits and vegetables that have a higher fuel value than the banana. Other fruits and vegetables that may be classed with the banana as having approximately 1 caloric per gram are grapes, plums and potatoes, together with figs, which are almost identical with bananas, and dates, with a fuel value equal to that of grapes.

Raw starch has not proved to be a satisfactory nutrient for the human body. No one thinks of eating the starchy potato uncooked; and the tolerance of the human alimentary tract for the uncooked starchy chestnut has decided limitations. It is obviously unwise, therefore, to expect the raw banana, eaten in the stage in which much unconverted starch still remains in the fruit, to prove free from the same objections that apply to other unripe or uncooked starchy foods. Even the green banana can be eaten with impunity if the pulp is thoroughly cooked, as is done in the case of the comparable potato. The chief reason for the unfavorable reputation attained by the banana, when eaten uncooked, appears to lie in the failure of most persons to understand what a ripe banana really is.

The chemist has closely followed the changes that the skin and pulp of the banana undergo simultaneously during ripening, a process facilitated by heat in the presence of air. Bananas that are merely yellow are not ripe. Pease and Rose remind us, in harmony with numerous published analyses, that characteristic changes take place in the peel as the fruit matures. The thick, turgid covering of the green banana becomes thinner and more pliable; the color passes from green to pale yellow, deepening to golden yellow with brown spots; and finally the peel becomes brown all over. Bananas are edible raw when the brown spots appear, and need not be refused as overripe when the peel is entirely brown if the covering is intact and the pulp shows no signs of fermentation. The brown color of the ripening must not be confused with the brown patches due to bruising.

The proof of the pudding is the eating. Utilization experiments have demonstrated that the underripe banana when baked is utilized to about the same extent as the potato, and is similar to this vegetable in its nutritive value. There has in no case been any suggestion of deleterious effects from eating the banana baked or raw when fully ripe. In the late yellow stage, before the development of the distinct golden color, the raw fruit can be consumed by normal persons in small quantities (say one or two bananas) without discomfort or apparent harm. Nevertheless the recent authors are of the opinion that the raw fruit should not be given to children at this stage. Pease and Rose have conducted enough actual feeding trials on young children to justify the statement that the banana can with profit enter liberally into the child's dietary, provided it is fully ripe or well cooked. If eaten baked in the yellow stage of ripeness, or if eaten raw when fully ripe, the banana makes a delightful and highly nutritious article of food. Its composition does not warrant the use of the banana as the main component of the child's dietary, but it can compete well with other fruits, and is decidedly to be preferred to candies. The nutritional value is relatively high, approximately one calorie per gram of pulp; and its carbohydrates, when it is fully ripe or cooked, are not less assimilable than those of cereals and potatoes. In the raw food, the digestibility is directly proportional to the ripeness of the fruit. There is no positive evidence that the banana influences bowel movements. In the many tests there was no suggestion whatever of any deleterious effect from consuming large amounts of fully ripe bananas. Prolonged use of the underripe fruit, on the other hand, developed undesirable symptoms.

Let the important fact be emphasized again that the banana ought not to be eaten raw until after the brown spots begin to appear. At this stage, we are reminded by the investigators cited, the banana assumes a full golden yellow and is in its most attractive appearance. A completely browned skin, they properly add, is not in itself a sign of overripeness, and such fruit should be judged by the texture of the pulp. The brown color of the peel, however, should not be confused with the darkening due to bruises. An injured banana is soon invaded by molds and yeast cells through the abrasions and the broken end; the banana "finger," therefore, should not be broken from the "hand" or stem, but cut off in such manner as to leave a good margin between the cut surface and the pulp.

---

[4] Pease, M. C., and Rose, A. R.: The Banana as a Food for Children, Am. Jour. Dis. Child., November, 1917, p. 379.

When we have at length learned to recognize ripeness in the banana and have ceased to eat the unripe fruit because we mistake its yellow tinge as the sign of a wholesome stage, we may further come to appreciate a positive advantage in the "sterile package" represented by the undamaged peel. Bailey's investigations have shown this to be practically impervious to bacteria. Therefore — and this is worthy of distinct emphasis — a banana properly handled is "uncontaminated by dirt and pathogenic germs even if purchased from the push cart in our congested streets." How many other foods that are edible without cooking can make an equally meritorious claim?

MILK PRODUCTION AND DISTRIBUTION

We have several times referred to the growing importance of the economic aspects of milk production and distribution. The cost of milk to the consumer is so intimately bound up with public health interests that it has long been impossible to separate sharply economic and sanitary issues. Under the pressure of war conditions, this relation is becoming closer than ever.

New York investigators have found that in October of this year a definite decrease in milk consumption in that city could be noted. In 2,200 families visited, the daily amount of milk produced had fallen to 3,193 quarts, as compared with 4,797 quarts in the previous year. Coincident with the decrease in amount of milk purchased, there was a shifting from the better grades of milk to the cheaper, 266 families abandoning Grade A milk for Grade B, and sixty-seven changing from Grade B to Grade C. Dipped milk also was substituted for bottled milk, and the sale of condensed milk increased. The investigators found that 2,148 children under 6 years of age were drinking tea and coffee. In view of these facts, it is not surprising that the New York City Health Department believes that the recent increase in infant mortality in that city is due to a decreased use of high grade milk.

It is, indeed, high time that we should have the cost investigations that are now being made or projected in various parts of the country. If competent investigators are armed with ample authority to secure the facts, some interesting results may be anticipated. Certain opportunities for inquiry and reform have been evident for a long time. The waste involved in current distributing methods appeals to the most superficial observer as quite without justification. In the well known Rochester, N. Y., investigation, it was found that in one small section of the city, fifty-seven dealers delivered milk to 363 homes, traveling altogether some 30 miles. The same service could have been given by one distributer traveling 2 miles. Plans for cooperative dealing have been worked out; why are they not put into effect? Committees meet, discuss and decide, but no action is taken. Selfish interests—always a little more persistently aggressive than unselfish—contribute powerfully to a policy of inaction. Some observers express much curiosity as to the profits of the large milk distributing companies, not merely at the present time but during the last ten years. Has the public been getting a square deal?

Then there is the dairy farmer, himself, that potent political factor in all agricultural states. What state official is going to "antagonize" the rural vote? In many state legislatures the country members outnumber those from the city districts. State institutions are dependent on the legislature for their appropriations. Is it a fact that the actual cost of milk production warrants the enormous price increase that has taken place all over the country in the past few months? Crops of the chief cattle foods are said to have been very large in most sections. The cost of producing and storing these foods may have increased, but not greatly for the average farmer, tilling his own soil and milking his own cows. Does the increased price demanded by the farmer for his milk represent a genuine rise in cost production, or is the traffic being charged all it will bear? One responsible health officer over his own signature answers this question in no uncertain way.[1]

It is to be hoped that the investigations now under way will be real investigations, and that the questions here raised will be answered authoritatively. This is no time for hoodwinking ourselves or others, or for being tender with the feelings of selfishly interested groups, or for resting content with half way information or half way measures.

LOW ARTERIAL BLOOD PRESSURE

The emergency of the war, with its countless experiences of surgical shock, has directed attention to the problems of low blood pressure more emphatically than has ever been done before. Recent timely experimental contributions to this subject in THE JOURNAL by Pike and Coombs,[2] Henderson and Haggard,[3] and Guthrie[4] bear witness to the importance and the intricacy of this much debated topic. It would be both futile and presumptuous to attempt in a brief editorial comment to unravel the difficulties presented. It may be worth while, however, to note for the reader less well versed in the phenomena encountered in connection with shock, that low arterial pressure, per se, may be due to at least two quite different causes, apart from failure of the heart itself. An actual deficiency of blood in the circulation, such as occurs after marked hemorrhage, reduces the output of the heart so that it may become insufficient to take the place of the blood flowing through the capillaries. The obvious form of relief for this condition is to replace effectively the fluid lost. Constriction of the arterioles may raise the blood pressure; but as Bayliss[5] has clearly pointed out in a review of the subject, while it is evident that constriction of the arterioles would raise the pressure in such cases, by diminishing the rate of outflow through the capillaries, the result would be to decrease the supply of blood to all organs whose arterioles are affected, so that no real gain would be obtained. There is an abundance of evidence now at hand to show that when arterial pressure is lowered through loss of blood it cannot be brought back except to a certain degree by the injection of simple saline solutions in a volume equal to that of the fluid lost. The fluid thus introduced rapidly leaves the blood vessels, in small part perhaps through prompt elimination by the kidneys, but in far larger measure by passage into the tissues, as has been pointed out by Bogert, Underhill and Mendel.[6] Several investigators have maintained, and in this they are supported by Bayliss, that if the viscosity of the solutions injected to replace lost blood is raised to that of blood, as can be done by using gum or gelatin solutions in saline, the restoration of blood pressure and volume is far less transitory than is the case with saline solutions alone. The difference in this case, says Bayliss, is due to the osmotic pressure of the colloids injected, by which loss of water by the kidneys and to the tissues is prevented. In animals this has been accomplished by the addition of gelatin or gum acacia to Ringer's solution. Colloids that exert no osmotic pressure are ineffective. Perhaps the intravenous injections of glucose as performed by Erlanger and Woodyatt[7] will prove more satisfactory.

[4] Guthrie, C. C.: Experimental Shock, THE JOURNAL A. M. A., Oct. 27, 1917, p. 1394.

But there is another condition of low blood pressure in which the volume of blood is entirely normal, even when the heart is beating efficiently. The result is due in such cases to peripheral vasodilatation. Bayliss has well analyzed this situation by saying that what is here required is clearly to restore the normal tonic contraction of the vessels. In these circumstances an increased volume of blood may be useless or even harmful, if the heart cannot correspondingly increase its output. Even when no sign of heart failure can be detected, however, injections of suitably viscous saline solutions do not produce any permanent rise in arterial pressure in this category of cases. The vasomotor mechanism is not exhausted under these circumstances, so that the employment of suitable substances to act on it may bring success in restoring the pressure. It is a striking fact that a fall of arterial pressure by itself produces peripheral vasoconstriction through nervous channels; and a rise in pressure appears to induce vasodilatation.

These distinctions, already familiar to the intensive student of the circulation, need to be impressed on all who tend to put every instance of low arterial blood pressure into a common category and assign it to a uniform cause. In shock one has to deal with even more complex conditions in which the condition of the venous circulation, the nutrition of the nervous centers, an altered chemical composition of the circulating medium, and perhaps other as yet entirely unanticipated factors referable to the tissues themselves may play the decisive rôle.

Current Comment

CHOLESTEROL ESTIMATIONS IN BLOOD

The rapid development that the clinical chemical examination of the blood has experienced as a diagnostic technic in the past few years has led to the exploitation, so to speak, of various blood constituents as indexes of functional derangement. In some cases these attempts have been successful in offering new or better indications of pathologic conditions that cannot be so well diagnosticated by other means now available. These contributions, notably such as relate to the nonprotein nitrogen, the uric acid, the sugar and the lipoid content of the blood, have repeatedly been referred to in The Journal. With an extension of the use of microchemical methods in clinical laboratories, and the accumulation of first hand experience regarding what they can reveal in the clinic, a better critique of chemical blood analysis will gradually be evolved, and the demonstrably useful features will be retained as a part of the laboratory routine. This entire phase of clinical observation is passing through much the same stages as were traversed in the development and perfecting of the now highly successful and invaluable methods for the morphologic examination of the blood. With this preface we may refer again to the subject of the cholesterol content of the blood, summarizing the best evidence available up to the present time. The hopes of the past have not all been realized. It seemed likely at one time that hypercholesterolemia would prove to accompany cholelithiasis. Indeed, the formation of gallstones has been charged to a high content of cholesterol in the blood. The latest statistics, by Gorham and Myers[1] of the New York Post-Graduate Medical School and Hospital, indicate that the findings in cholelithiasis are quite inconstant. They conclude that since hypercholesterolemia may be found in many conditions and is not uniformly constant in cholelithiasis, it would seem that the blood cholesterol possesses only a limited diagnostic usefulness in this condition. Gorham and Myers agree with several previous observers[2] in the conclusion that in pathologic conditions hypercholesterolemia is comparatively common, being reported in arteriosclerosis, nephritis, obstructive jaundice and diabetes, though it is not invariable in these diseases. A content of cholesterol lower than normal is a greater rarity, however. It has been recognized for some time to occur particularly in anemias, notably those of the pernicious type. Here it may have considerable significance, especially in view of the reputed antihemolytic action of cholesterol. The possibility of cholesterol administration at once suggests itself; but it is still too early to foresee the result of such procedure with any certainty. The occurrence of an augmented quantity of cholesterol in diabetes is in harmony with the lipemia that so often occurs in this disease; so that cholesterol may perhaps here be taken as an index of the lipoid content of the blood and of diabetic lipemia in general.

NEPHRITIS, BLOOD LIPOIDS AND ACIDOSIS

The pathologic manifestations of nephritis are no longer interpreted solely in the light of the altered excretion of urinary products as a result of defective kidney function. Frequently there are more remote disturbances of physiologic performance attributable in ultimate analysis no doubt to the renal defects of the organism, yet not explicable directly as kidney phenomena. The confusion of cause and effect in relation to nephritis has been illustrated in the occasional coincidence of gout and nephritis. An illustration of an abnormality associated with certain stages of kidney disease, yet not obviously concerned with inability to excrete urine, has been clearly presented by Bloor[3] at the Harvard Medical School in a study of the blood lipoids by the analytic methods so successfully elaborated by him. The abnormalities in severe nephritis were found to be a high content of fat in the plasma and corpuscles, and an increased amount of lecithin in the corpuscles. The cholesterol values remain essentially normal. These abnormalities are the same as are found in alimentary lipemia, and for this reason are regarded as the result of a retarded assimilation of fat from the blood. Bloor points out that the most frequent of other conditions in which abnormalities of the blood lipoids are common is diabetes, and a prominent symptom of severe diabetes is "acidosis"—a decreased "alkali reserve" in the blood. Recent investigations[4] have established the fact that acidosis is frequently a feature of severe nephritis, and in most of the cases of certain types studied, acidosis was probably present, as evidenced by the dyspnea, low carbon dioxid tension in the alveolar air, and coma. Since an adequate alkalinity of the blood and tissues is necessary for their normal functioning, it seems very probable, says Bloor, that the retardation of fat assimilation found in nephritis is one manifestation of a general phenomenon brought about by a decreased blood and tissue alkalinity. After all the defects for which acidosis has recently been made responsible, what detrimental features of a depleted alkali reserve are we to expect next?

CLEMENCEAU—A PHYSICIAN

The man of the hour in France is Georges Clemenceau, noted as an editor, as Prime Minister of France, as a "wrecker of cabinets," and characteristically as "the stormy petrel of French politics." It will come as a surprise to physicians to know that this conspicuous figure in the political life of France is a physician, the son of a physician, and that for a time, according to the New York *Times,* he practiced medicine in Stamford, Conn., and in New York. Clemenceau was born in 1841, was licensed to practice medicine in 1865, and between 1865 and 1869 established himself on West Twelfth Street in New York City. Failing in the practice of medicine, he became an instructor of the French language and literature in Miss Aikens' Young Ladies' Seminary at Stamford, Conn. Here he married one of his pupils, Miss Mary Plummer of Springfield, Mass. He returned to France in 1870. Of his career as a physician but little is known. Among his works is one on the "Generation of Anatomic Elements." It is quite probable that his training as a physician influenced his political career. We quote from an article in the *Nineteenth Century,* 1907:

> The materialist doctor in him does not shrink from the ridicule one incurs by talking about a "total view of the universe," but the idealist appears at every moment in the social reformer.

Public Instruction in Cooking.—The Ministry of Food of Great Britain, and the London County Council, have provided facilities for instruction in cookery. According to *Commerce Reports* a number of schools have been established for teaching how to cook war foodstuffs, where persons may take the course without cost. The London County Council has a number of traveling kitchens equipped on motor cars which travel about London giving demonstrations on such subjects as: voluntary rations; food that serves the same purpose as meat; how to get the best value for money; substitutes for wheat flour; use of oatmeal, barley flour, maize meal and other cereals; economical use of sugar, aids and substitutes; catering for a week; unwise purchasing; the evils of underfeeding; the relation of price to value; kitchen economies; the fireless cooker, the "hot water jacket" and similar apparatus, and other devices for the saving of fuel. Courses in domestic economy have been provided in both the day schools and evening institutes. Children are required to attend these schools between the ages of 5 and 14 years. The course in domestic science is taken during the last two years of their attendance. Pupils devote one-half day each week to this subject. In some districts pupils devote half of the week for three to six months to these courses. The materials prepared in the cookery schools are sold to the children and teachers at about 90 per cent. of their cost. In January, 1917, there were 178 cookery centers, 56 laundry centers, 128 combined cookery and laundry centers, and 72 housewifery centers, providing for about 65,500 children. In addition to this there are evening instructions in war time meals, and advanced courses in domestic science offered by the polytechnic institutes.

Medical Mobilization and the War

MEDICAL OFFICERS NEEDED BY NAVY

Surgeon-General Braisted of the United States Navy announces that the Navy has not yet reached its maximum in needs for commissioned medical personnel, and that it is still welcoming offers of service for such duty. THE JOURNAL will be glad to send to physicians who are interested in this service a circular of information, and application blanks.

RED CROSS ACTIVITIES IN ITALY

Temporary organization of Red Cross agencies in Italy to meet the present emergencies has been perfected. Carl Taylor has been installed as general manager in Rome, and Edward Ayre Hunt has been placed at the head of the civilian relief department.——Ambulance companies and other personnel have been transferred to Italy from France. Money has been appropriated for buildings in Genoa for receiving refugees, and the king has turned over his royal villa at Monzo, to refugees from the invaded regions of Italy.

ANTITUBERCULOSIS WORK IN FRANCE

The mission headed by Dr. Livingstone Farrand sent to France by the Rockefeller Foundation to combat the threatened increase of tuberculosis in that country will organize its work into three sections. It is planned to establish in one of the arrondissements in Paris and in certain large provincial towns organizations consisting of dispensaries, clinics and laboratories and provision for domiciliary attendance. This work will be under the direction of Dr. Miller. A second section under Dr. Charles White will undertake the distribution of assistance, and a third section under Professor Gunn will deal with publicity. This section has already begun its work in the organization of traveling exhibitions, meetings, kinematograph displays, etc.

REGULATIONS UNDER SELECTIVE SERVICE LAW

Section 151 B of the new selective service regulations concerns especially medical students and hospital interns registered under the law. It becomes effective December 15.

> "Except in the following cases, no registrant may enlist voluntarily in the military or naval service of the United States.
>
> "Under such regulations as the Surgeon-General may prescribe and on receiving permission from the Surgeon-General to do so, any medical student, hospital intern, dentist, dental student, veterinarian, or veterinary student may enlist in the enlisted reserve corps of the Medical Department, and thereafter on presentation by the registrant to his Local Board of a certificate of a Commissioned Officer of the Medical Department of the Army that he has been so enlisted, such certificate shall be filed with the Questionaire and the registrant shall be placed in Class V on the ground that he is in the military service of the United States. There is no other ground on which such persons (as such) may be placed in a deferred classification."

The effect of classification in Class V is to exempt or discharge from the draft. Regulations to carry out these paragraphs will be issued by the Surgeon-General. The effect of the new regulations will be to extend to first year medical students, after Dec. 15, 1917, essentially the same privileges in respect to Army service as are now enjoyed by students of the second, third and fourth year classes. The approval of the Surgeon-General will be granted to such students in well recognized medical schools only.

Since, under existing conditions, it is extremely unlikely that further calls for the present draft will be made before December 15, the fear expressed by first year medical students that they may not be able to continue their medical course is unwarranted, if they have not already been cited for the draft by their local board. In that case, the Medical Department has no authority.

NEWS OF THE BASE HOSPITALS

Base Hospital No. 30 Mobilized

Base Hospital No. 30, organized in the University of California Medical School, has been ordered to mobilize for the training of the enlisted personnel at Fort Mason, San Francisco. For this purpose it has been placed under the command of Col. Elmer A. Dean. Most of the officers of the organization have already had military training, and at present are in active service in various parts of the country. Those ordered for immediate mobilization with the unit are: Major Eugene S. Kilgore, director and chief of medicine; Capts. Jule B. Frankenheimer, Louis P. Howe and Arthur L. Fisher, and Lieuts. Malcolm Goddard, Hiram E. Miller and John M. Rehfisch.

The remainder of the official personnel are to be assembled when the organization is ready for foreign service. These include: Drs. Elbridge J. Best, Ernest H. Falconer, Arthur C. Gibson, C. R. Giles, Charles M. Richards, Howard E. Ruggles, Hudson Smythe, Charles L. Tranter, Herbert S. Thomson, William W. Washburn, Alanson Weeks, Nathan P. Wood, J. Homer Woolsey and Harold W. Wright.

NEWS OF THE TRAINING CAMPS

Fort Riley

The closing of the training camp at Fort Benjamin Harrison has brought a number of new men to Fort Riley. Lieut.-Col. William H. Tefft comes to take command of Evacuation Hospital No. 7, to which Major Don C. Peters from Camp Sheridan, Ala., has also been assigned. Major S. J. Turnbull from Fort Benjamin Harrison is in command of Hospital Train No. 24. Lieuts. D. C. Sherman, Albert V. Braden and G. L. Longworthy from Fort Benjamin Harrison are assigned to Evacuation Hospital No. 7; also Lieut. S. D. Bevill, who comes from Camp MacArthur, at Waco, Texas. Major Maurice H. Krebs has reported from Fort Benjamin Harrison as an instructor. Two motor driven evacuation ambulance companies have been organized to which have been assigned Capt. Harmon H. Ashley and Lieuts. George J. Culver, Theodore M. Wiersen and Frederick H. Spencer, all from Fort Benjamin Harrison.

QUARANTINE AT CAMP FUNSTON

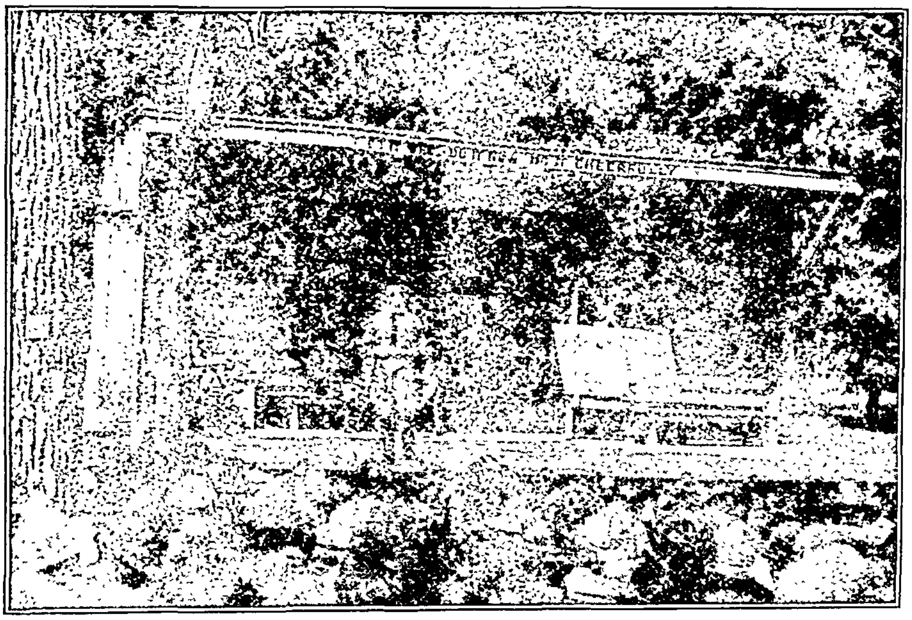
Dry weather still continues. Practically no rain has fallen since October 25. Heavy fogs every morning keep the dust down, but the days are clear and warm. Efforts to control dust-borne diseases, especially pneumonia and meningitis, have resulted in quarantining Camp Funston. All student officers and instructors at the medical officers' training camp have been forbidden to enter Camp Funston except on official business. At the same time, all officers and men at Camp Funston has been forbidden to use the street cars, or to attend moving picure shows, theaters, or dances at Junction City, Manhattan or Army City. An isolation camp has been established outside Camp Funston, in which have been placed all contacts, suspects and carriers. Active measures are being carried on for the sterilization of carriers, the prophylactic treatment of contacts and the improvement of hygienic conditions. Overcrowding in company barracks has been greatly reduced, and adequate ventilation is being enforced. As a result, meningitis is markedly diminishing in Camp Funston, and last week's report showed simultaneous falling off in pneumonia. So far, Fort Riley has escaped any meningitis invasion, and the number of cases of pneumonia have been small.

THANKSGIVING WEEK

But the real event of the week has been Thanksgiving. For the first time in years in most cases, and for the first time in their lives in some cases, medical officers spent Thanksgiving away from their families. Leave for seven days was given to half of the instructors, and to all student officers whose work was completed. Furloughs were given to 10 per cent. of the enlisted men. Many spent the day in Kansas City, Topeka and other nearby cities. But the majority of the men remained in camp. All classes were off, and all unnecessary work was discontinued. The Sunday and holiday routine was followed. True to American traditions, the principal function of the day was the Thanksgiving dinner. In each mess hall at 12 a bounteous meal was served, consisting of soup, roast turkey with oyster stuffing, mashed potatoes and gravy, celery and olives, green peas, tomatoes and other vegetables, mince and pumpkin pies, ice cream and coffee. The turkeys were a prime lot which had been brought to the reservation alive and fattened for several weeks. The mince pie was the real New England variety, and contained some ingredients that never were made in Kansas. In fact, one enthusiastic and well fed officer was heard to declare after dinner that his piece of pie was the first real drink he had had since he left home.

Sanitary Instruction at Fort Riley

In the past four months a project has been developed at the medical officers' training camp which we believe in many ways is unique in this country. This is a field sanitary laboratory (1) to train medical officers in the use and construction of the various types of sanitary apparatus which they might be required to construct in the field, and (2) to make a study of the different types of apparatus in current use, with a view to their betterment or the development of new and more efficient types. The laboratory is outdoors, occupying a considerable area of ground. A reserve corps medical officer in charge of an evacuation hospital may be called on to decide what he will do with the excreta, human and animal, of his organization. He may decide to burn it, as one solution of the problem. With no sewers, and no stream to help him out, he must dispose of the solid and liquid excreta of the thousand or more patients and soldiers for whose health he is directly responsible. The incineration of human excreta, especially when highly infective, requires special apparatus which must be constructed out of any materials available; that is, must be really "home-made," and yet must be perfectly efficient. After the regular course of lectures in hygiene and sanitation, the students are taken over in small groups to the laboratory and shown many of the approved types of apparatus for this purpose. These are carefully explained, often shown in operation, the relative merits of the different types elucidated, and the conditions under which one might be available, and another not available, thoroughly gone into. The question of manure may be be taken up. How is it to be disposed of and how is fly breeding to be prevented while it is being disposed of? The various methods of doing this are shown, and the apparatus, necessarily large and cumbersome, and the essential points of construction are explained. All of these have been made by the enlisted men, under the guidance of the director and his associates, and with no skilled mechanics to help. A large Panama railroad iron incinerator for manure was built. This involved the use of old rails, and something over ten tons were required. The Union Pacific lent some old rails, which had to be dragged by mules for several miles. These were drilled on the ground, U-bolts were made out of bar iron by the blacksmith of an ambulance company in his portable forge, nuts made from flattened horseshoes cut into squares were punched and threaded, and the whole was put up on six piers made from stone collected from the adjacent hill. This sort of work can be learned only by seeing the actual thing itself. Moreover, each class is now required to make drawings and actual plans of these pieces of apparatus, and a wholesome rivalry has grown up among the officers. Lately one can see a dozen or two officers with their camp stools perched in front of a field oven, a special latrine, an incinerator or what not, drawing away for dear life.



A lecture at the Medical Officers' Training Camp, Camp Greenleaf, Fort Oglethorpe, Ga. Major James B. Griffin, M. R. C., lecturing.

About forty pieces of apparatus have been constructed, and a considerable number are now on the road to completion. For the winter a large 50 foot tent has been set up on a frame and boarded in. Part of the work will be carried on there in inclement weather. At present a large apparatus for delousing clothing is nearly finished, and especial attention is being turned to the means of combating vermin in general.

The second purpose of the laboratory has been investigation, so far as this is possible with the faciities at hand. This has, however, already borne fruit in that a new incinerator, especially adapted to the needs of such organizations as a field hospital or evacuation hospital when immobile, has been devised, and has been put into successful operation. It is hoped it will develop into a standard type, especially since the waste heat is utilized, which means a great saving in fuel, which is so important under present service conditions. One other departure in the form of a portable latrine has been developed here, and many small improvements on existing apparatus. The exhibit was commented on favorably by the English and French commission when at Riley, and during the past week the commanding officer, Lieutenant-Colonel Bispham, has received instructions from Washington to have blueprints made of all exhibits and expedited to the Surgeon-General's Office. This will have been completed by the time this reaches our readers. The work will be carried on through the winter months and into new lines.

The director, Major Charles Spencer Williamson, M. R. C., and his associates, Capt. J. G. Shewbrooke, M. R. C.; Lieut. William E. Pretts, M. R. C., and Lieut. David Schmalhorst, M. R. C., are endeavoring to make the scope of the laboratory entirely practical, but governed by the same aims as any civil laboratory. At present, two modifications of a certain standard device are being tested, side by side, in respect to fuel consumption and rapidity of operation, so that when one type is recommended it will be on the basis of actual comparative experimental evidence.

The activities of the laboratory are quite diverse. Methods and apparatus for disposal of garbage, for delousing clothing, for disposal of manure, for prevention of fly breeding, for incineration of solid excreta, for disposal of sullage water, for destruction of flies, for preservation of food in the field, and for improvisation of field cooking apparatus are some of the subjects receiving attention.

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

Assistant Surgeon-General Rucker, U. S. P. H. S., visited the camp last week, while inspecting the work of the service in Macon and the area about the camp. The Public Health Service has been of great assistance by cleaning up the surrounding country, and especially by putting the dairies, ice cream factories, restaurants, etc., in a sanitary condition.

MEASLES

Our measles epidemic will soon be a thing of the past. The maximum number of cases was 1,201, and the greatest number of admissions in one day was 175. The epidemic began, October 22, was at its height, November 14, and was practically over by December 1. Of approximately 10,000 new men who came into the camp, 3,000 developed measles. It appears that the nonimmune in the draft men amounted to 30 per cent. of the whole. We are all glad now that the thing is over, instead of having it drag along for months, while we are on the way and in an inclement winter climate.

PNEUMONIA

The greater part of the pneumonia has been found among the new draft men, not in the old guardsmen. Major Zinser, M. R. C., has arrived from the Surgeon-General's Office to make a thorough epidemiologic study of pneumonia. Colonel Duncan asked this of the Surgeon-General when he was here. Both General Gorgas and Professor Welch thought it necessary and promised the help of the Surgeon-General's Office and the Rockefeller Institute in the study of pneumonia to its final analysis. Pneumonia stands in the same relation to the camp of 1917 that typhoid did to the camp of 1898. The origin and transmission must be elucidated as the origin and transmission of yellow fever, typhoid, meningitis and other epidemic diseases have been elucidated.

The whole division is now supplied with overcoats. This will surely reduce the amount of bronchitis, grip and pneumonia.

FOOD CONSERVATION

Captain Eddy, M. R. C., and three assistants are at work in the camp studying the conservation of food. It is to be noted that they will reduce the amount of waste, whether or not the ration can be safely reduced.

BASE HOSPITAL NOTES

Major Halsey arrived Saturday, November 24, to take charge of the medical service. Major Hans Zinsser is now chief of the laboratory staff. Major Black of the Surgeon-General's Office spent two days at the hospital and gave a very interesting and instructive talk. The staff has been augmented by the arrival of sixteen new officers, twelve of whom are quartered in framed pyramidal tents. The nursing corps was increased by the arrival of a "carload" Wednesday morning. Lieutenant Cook has returned from New Orleans after taking a special course in fracture surgery. There are at present under treatment in the hospital 991 patients.

ONE HUNDRED AND SIXTH SANITARY TRAIN

The ambulance service of the camp has received many compliments on the efficient service rendered. Ambulance Company No. 121, commanded by Capt. Robert Ashworth, Alabama, has been permanently detailed on this service with good results.

We are much pleased at the low sick rate we have been able to maintain in the train, having consistently maintained the lowest rate of any unit in the division, despite the fact that during the recent epidemic of measles our men worked longer hours and were subjected to more general exposure than those of other units. Lieutenant Plante of the British Army lectured to the medical officers' class recently and gave many valuable tips and suggestions which we hope will prove helpful when we reach the trenches. Captain Crupper, Infantry, British Army, will talk to the medical officers' class on medical organization as carried on on the western front.

Thirty-Fifth Division, Camp Doniphan, Fort Sill, Okla.

SANITARY POLICE

The most important development of the past week was the establishing of a sanitary police, under control of the division surgeon, for the city of Lawton. For some time there has been a growing feeling that the insanitary conditions in the city of Lawton would sooner or later mean trouble both for that community and for the soldiers that go to Lawton. The facilities of Lawton to meet the wants of the military population of Camp Doniphan, more than twice the population of the city of Lawton itself, were obviously inadequate. The ambitious vender who would sell "red hots" and soft drinks to soldiers that were eager to get a variation from the regular camp mess did a flourishing business, in which the exchange of his wares for the good cash of the soldiers was the primary consideration, rather than the care and cleanliness with which the food was prepared.

The important work of regulating and controlling the situation has been detailed to Major W. S. Lawrence, M. C., N. G., who has been made assistant health commissioner for the city of Lawton. Under his immediate supervision, there has been established a first-aid station where venereal prophylaxis is given. There has been established also a municipal isolation hospital where the city's cases of contagious diseases will hereafter be treated. Aside from the military police, Major Lawrence will have the assistance of two experienced sanitary inspectors furnished by the state board of health.

Possibly for the first time in their existence the hotels and restaurants of Lawton have been asked to clean up and maintain cleanliness in their kitchens. Since the order to clean up will be controlled by the stationing of military police at the door of the establishment that fails to comply with the order, there can be no doubt that the orders will be promptly complied with. Drs. Duke and Sapper of the state health office have been in conference with Major Lawrence, the city officials and leading business men of Lawton, and the combined efforts of these men, no doubt, will succeed in providing for Lawton the long needed sanitary improvement.

DISEASE INCIDENCE

There were but two deaths to record for the past week, one from meningitis and one from pneumonia, the latter following a case of typhoid fever. The latter case is of interest in that the patient had received his last immunization against typhoid and paratyphoid one week before the development of his illness. All together, the health of the camp is very good, the morbidity rate, inclusive of injuries, being just a fraction above 3 per cent.

CARDIOVASCULAR EXAMINATIONS

Capt. Ralph C. Brown, M. R. C., has completed his work on cardiovascular conditions; a total of 487 cases were examined by him. Of these men, 354 were accepted and sixty-seven rejected; sixty-six were conditionally accepted for special service and will be transferred to the base hospital, where they will be under further careful observation and where tracings will be made to determine more fully their condition. Captain Brown reports that the majority of rejected patients showed mitral stenosis. This is rather interesting, since most of these men had been subjected to physical examination two or three times before they were brought before the cardiovascular board. Among other interesting findings of this board are a case of transposition of the viscera, and one of traumatic aneurysm of the carotid artery, following injury to this vessel from a stab wound.

PERSONAL NOTES

Capt. Ralph C. Brown, M. R. C., of the cardiovascular board, returns to Chicago, going temporarily on the inactive list until Base Hospital No. 13, of which he is a member, is ordered out.

Lieut. J. W. Follin, sanitary engineer, has been added to the staff of the division surgeon.

Seventy-Seventh Division, Camp Upton, Yaphank, N. Y.

During the past three weeks many promotions have been announced in the medical personnel of this division. In the new base hospital the services have now been well organized, and in many instances specialists of international reputation have taken charge of their respective special departments.

DISEASE INCIDENCE

We have thus far been singularly fortunate with our pneumonia patients. They have not been numerous, and there have been no deaths, a result which appears to be largely due to the early employment of the Cole serum. Most of our cases seem to be of the Type I infection, which is fully recognized to respond most satisfactorily to this method of treatment. Highly mixed infections have not been frequent, doubtless also accounting largely for our good fortune thus far.

The death of Major Richard Weil, who was intimately known to many of the workers at this cantonment, has been much regretted by all members of our staff.

Our good fortune in regard to the contagious diseases has been thought to be largely due to the fact that we have thus far drawn our recruits chiefly from a dense urban population in which, naturally, the susceptible material has passed through these standard infections in large part before coming to the cantonment. It is difficult otherwise to account for our very small percentage of measles, mumps and diphtheria. Only a single case of the last mentioned contagion has appeared at the base hospital, and our few sporadic cases of mumps have thus far shown nothing of an epidemic character. In the past the same statement was true also of measles, which has been such a serious factor in some camps, particularly in those drawing their material from a largely rural population. The recent assignment of colored troops from the South to Camp Upton bears out in a very striking way this assumption. Among the colored troops from New York City and its environs, now numbering several thousand, not a single case of measles or mumps has developed; but in a small battalion of those from the South, ten cases of measles and two of mumps appeared within the first week. Rigid quarantine measures have been enforced, however, and it is hoped that in this way we may at least prevent the spread of these diseases to other troops.

PSYCHOLOGIC TESTS

An interesting side light on the question of the alleged conscientious objector has been developed by the findings of a psychiatric board composed of Major Hammond, Captain Rosanoff and Lieutenant Pearse. Excluding those who for natural, national and entirely honorable reasons desire to evade service in our Army, this board found that nearly 90 per cent. existed in instances of clear mental disease or degenerates. It is regrettable that public examinations of this character of the nonmilitary population cannot be conducted, and that the defectives of this type outside as well as within the Army should be confined in asylums or similar public institutions.

MENINGITIS

A single and early fatal case of epidemic cerebrospinal meningitis has appeared in the camp. Apparently the case originated from an extramural infection, and thorough examination of all contacts has disclosed no carriers as yet.

ANTHRAX

A somewhat unusual case of anthrax was discovered in which the clinical diagnosis was that of a septic meningitis, possibly epidemic. Lumbar puncture showed the cerebrospinal fluid to be turbid with a growth of anthrax bacilli. Postmortem examination showed the infection to have probably been of intestinal origin, although one skin lesion suggested the possibility of inoculation through this avenue. This also seems to have been acquired outside the encampment.

NOTES

The weekly meetings of the Upton Medical Society have been largely attended, and the programs have been of a very high and instructive character. Major E. K. Dunham gave us a most interesting illustrated talk on the newer methods of antisepsis. Major Thomas Darlington discussed fatigue. Lieutenant Pelitier of the Medical Corps of the French army gave a most interesting lecture, illustrated by lantern slides of the Carell-Dakin method of treatment of surgical injuries and wounds. Dr. Haven Emerson, commissioner of health for New York, discussed the subject of tuberculosis, chiefly from a statistical standpoint and concerning its methods of propagation, especially as applied to such compact communities as the military camp. Next week the medical society is to be addressed by W. H. Park, director of the Research Laboratories of the New York Board of Health.

Among the distinguished medical visitors of the camp have been Rufus Cole, Alfred Kohn and A. R. Dochez from the Rockefeller Institute.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

Orders have been received regarding equipment and baggage that may be taken by troops designated for duty with expeditionary forces in Europe. Each officer below the grade of major, and each contract surgeon, acting dental surgeon and acting veterinarian may have baggage not to exceed 250 pounds. This allowance includes Equipment C, professional books and all necessary clothing and bedding for extended field service. Containers for personal baggage for the above named officers shall be the standard trunk locker and bedding roll or similar containers of their approximate equivalent volume. Mosquito bars, head nets and khaki clothing will not be taken.

PSYCHOLOGIC TESTS

More than 10,000 men have been given the intelligence tests by the psychologic board that is now sitting at Camp Zachary Taylor. The board is headed by Lieut. Marion R. Trabue, chief examiner, formerly engaged in psychologic work at Columbia University. Other members are Lieut. Clarence S. Yoakum, University of Texas; Lieut. Heber S. Cummings, Kansas Agricultural College; Lieut. Edgar A. Doll, Cornell University; Dr. Eugene C. Rowe, Michigan Normal School; Dr. James W. Bridges, Ohio University; Calvin P. Stone, Jeffersonville Reformatory, and John K. Norton and J. David Houser of Leland Stanford Junior University.

The men are graded after examination by scores ranging from zero to 414, and are arranged into five grades, from A to E. For a man to make Grade A, his score must be between 300 and 414. This is known as the very superior grade, and the Grade A men are characterized as being skilled in abstract thinking. Grade B ranges between 250 and 299. This is the superior grade, and the one usually made by the typical officer. Grade C is the "average" grade, ranging from 100 to 249. This grade is usually made by the typical private. Grade D consists of the unskilled laborer class, is called "Inferior," and is from 50 to 99. The lowest is E, with scores ranging from zero to 49. These men are classed as "very inferior," and are dull, ineffective or feebleminded or nearly so. The majority of men of this class are recommended for discharge on account of deficient mentality.

The examinations are conducted in an unoccupied ward of the base hospital, an entire company being put through at one time. The examination is made out on a printed pamphlet consisting of about twenty pages. Each man is given a pamphlet and pencil, and is told what to do in each test by an instructor. The man must put a cross in the largest of a row of squares printed across the sheet, all different sizes, but nearly the same. He must at a glance underline the highest and lowest row of figures; take dictation of numbers and sentences, etc. The illiterates and others who fail at the written examination are given individual examinations to show their mechanical sense and skill. They are given bells and locks in pieces to be put together. If they do not show any mechanical skill, they are given the various tests used at institutions for the feebleminded and at emigrant stations. Failing these simple tests, the man is rated as being deficient in mentality and is discharged. In one group of 300 examined, the board found ten imbeciles. One private made the highest grade recorded, 409 out of a possible 414. All officers will be examined, and are expected to make 250 or over.

At Camp Lee, where the medical officers were examined, several were found to have made only "average" grades. The medical officer in command found on investigation that the men who had made the low marks had consistently bungled up paper work. They were watched more closely, and if they did not show any sign of improvement, they were discharged. At this camp the officers in the Engineering Corps ranked highest in the intelligence tests, followed by infantry, quartermaster and medical officers last.

Contrary to general belief, no amount of study seems to improve the men's grade. If given the same test two years from now, they would make practically the same grades, and they are believed to show completely the capability of the brain.

This rating of the men will be of great advantage to the officers. The quick thinkers can be chosen for important pieces of work. While some man may have a high grade from an intelligence test, he may not make a good soldier, as he may be both physically and morally wrong. The results are carefully checked over, and a form is made out with a complete list of names of each company with a man's grade opposite his name. A regimental list is also made out for the division commander. The board will probably complete its work by January 1, when it will probably be ordered to another camp.

It is believed here that the results of the intelligence tests will influence the selection of candidates for the next officers' training camp.

MEASLES

Measles has spread to nearly every company of the Three Hundred and Thirty-Fifth Infantry, composed mostly of men from southern Indiana, all but two companies being quarantined. Most of the patients have been taken to the base hospital, while the men with milder cases are kept in the regimental hospital.

Two Y. M. C. A. secretaries have gone into voluntary quarantine in order to serve the men in the two quarantined regiments.

BASE HOSPITAL

There are now 681 patients in the base hospital, sixty-three with wounds and injuries. With venereal diseases there are now on duty 363 gonorrhea patients, twenty-three syphilis, and nineteen chancroid patients. New measles cases, twenty-two in all, were reported during the week from eight different organizations. The total percentage of sick was 3.74 or, omitting "wounds and injuries," 3.31. The division comprises 24,716 men at present, with 1,034 reported sick. The total number received to date has been 27,000, and 2,017 have been discharged by the reviewing board. The tuberculosis board has been actively at work, examining each officer and drafted man. Pulmonary tuberculosis has caused a large proportion of the rejections, several of those rejected being officers. Trachoma has also caused a large number of rejections, most of these patients being from eastern Kentucky counties. Few patients with primary syphilis are being rejected, these being now treated at the camp. Men with tertiary cases are rejected.

Eighty-Fifth Division, Camp Custer, Battle Creek, Mich.

The most interesting event of the past week was the visit of Colonel Chamberlain of the Surgeon-General's Office. He made a complete inspection of all departments of the sanitary troops.

Major Edwards, the new sanitary inspector, is rapidly developing the plans of sanitation necesary for the well-being of the camp. He is particularly anxious to obtain the proper air space, floor space and head space in the various barracks so that the men in their sleeping quarters will have the proper ventilation. The fact that there is a minimum amount of pneumonia in the division speaks for the results of this plan of ventilation.

THREE HUNDRED AND TENTH SANITARY TRAIN

There is much of interest in the activities of the sanitary train. Football, basketball, orchestra, minstrel shows all make the long evenings pleasant for the men.

The field hospitals and ambulance companies are working in conjunction with each other in their plan of training. The ambulance companies are setting up dressing stations and are operating between the trenches and the field hospital which is set up a mile or two from the dressing station ready for action in every particular, each department fully equipped and ready for work.

The night time is being utilized for the purpose of training. It is understood that the wounded are transported at night. Major Jackson, director of ambulance companies, has worked out an original idea of training ambulance drivers to drive at night without lights. He works out his scheme by having the eyes of the drivers covered so that they cannot see, and then instructs them in feeling their way along the road. The major figures that they can learn conditions of the road and locations much in the same manner as the blind utilize their other senses in determining location. The men of the various companies are enjoying this night work tremendously, and are becoming proficient in doing all the work, such as tent pitching and striking and road work, as well as they do by daylight. One of the most difficult problems to teach men is definite location at night without the use of a compass. They are taught to work out directions so that becoming lost or walking around in a circle is practically impossible.

Eighty-Seventh Division, Camp Pike, Little Rock, Ark.

Camp Pike is receiving rapidly its quota of troops from the northern cantonments. These men are as a class robust, ruddy-cheeked, and physically fit. There is little evidence of an undernourished condition or of hookworm and anemia, a state of affairs widely prevalent among the men first received at this place.

The time-honored custom of "passing the buck" has not been entirely eliminated in this connection, a certain percentage of these northerners being in a physical condition warranting their discharge rather than their transfer to Camp Pike. Some of these drafted men who intentionally or through accident just prior to draft became unfit were sent on anyway and have been crippling about the camps for some time. These men are unfit for drill, and unless they can do office work, cannot be trained to any extent. A recent order from the War Department has been issued expressly for the purpose of stopping this practice. It is to the effect that whenever a county or parish sends up a man who proves to be unfit for military service, the man shall be returned to the board sending him and the board required to send up another man who is fit. A special board of examiners is now on duty at the base hospital for the purpose of expediting the return of these men to their respective boards. Lieut. John Thorpe, Chicago, who is at present attached to the Three Hundred and Twelfth Sanitary Train, is assisting the division surgeon in this work.

BASE HOSPITAL AT FORT LOGAN H. ROOTS

Fort Logan H. Roots, which is about 3 miles distant from Camp Pike, has been designated as the site of a base hospital of 500 beds, to supplement the base hospital at Camp Pike. Lieut.-Col. George F. Jueneman of the Medical Corps is to be in command. In order to build at Fort Roots a hospital of this size, it will be necessary to utilize the brick barracks at this post. The post hospital at Fort Roots was used as a base hospital for Camp Pike during the early days of the construction work at the camp. The location is ideal, Fort Roots being situated on a high bluff overlooking the Arkansas River.

Lieut. E. J. Wentworth, of the orthopedic staff at the base hospital, concluded his course of lyceum lectures with two lectures on the spine. Lieutenant Wentworth spent some time emphasizing the fact that medical officers should strive always to assume the "posture of a soldier." He said the criticism had often been made by line officers that too many of the medical officers did not "look or act like soldiers." Lieutenant Wentworth's lecture were followed by one by Major McKenna of the base hospital, formerly of Chicago, on surgery of the bones and joints. The lecture was illustrated with fifty-two lantern slides which showed what might be accomplished in the work on the joint cavities. One of the most interesting and entertaining lectures given at the lyceum course recently was one by Major Amos Gale Straw of Boston, who is in charge of the roentgen-ray department in the base hospital at Camp Pike. This lecture was general in character, and dealt with Major Straw's nine months' experience in an evacuation hospital in France. One of the major's amusing experiences was that of being continually mistaken in England for the noted movie actor, the late John Bunnie.

The following assignments of commanding officers have been made in the sanitary train: Major R. H. Davies, director of field hospitals and assistant adjutant of the Three Hundred and Twelfth Sanitary Train; Capt. Paul R. Howard, director of Field Hospital No. 345; Lieut. Charles D. Mason, director of Field Hospital No. 346; Capt. William Carstophen, director of Field Hospital No. 347, and Capt. James Slack, director of Field Hospital No. 348. In the ambulance companies, Capt. Nolan Stewart is in command of No. 345; Capt. John B. Steele of No. 346; Lieut. Charles Lerrigo of No. 347, and Capt. Thomas McCabe of No. 348. The first three field hospitals and the first three ambulance companies are motor drawn; the fourth field hospital and the fourth ambulance company are animal drawn.

HEALTH OF THE CAMP

Health conditions at Camp Pike are in the main very good. There has been some cerebrospinal meningitis lately, the focus of infection apparently being some troops brought from a northern cantonment.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

ISOLATION CAMP

An isolation camp has been instituted at Camp Funston for all men who have been in contact with patients that have developed contagious or infectious diseases here. The camp is located on the Pawnee flats of the Fort Riley Reservation, and consists of tents with wooden floors and sides. The training of the isolated men, none of whom are actually sick, will proceed just the same as though they were with their organizations, as far as this is practicable. Provisional companies are being formed from men belonging to the same regiments or organizations, and these men drill as units, being carefully watched for any symptoms of disease that might develop. The colored troops have a separate portion of the camp from the white troops. The camp is under the supervision of Lieut.-Col. Frank Weed, and is officered by members of the One Hundred and Sixty-Fourth Depot Brigade. The cooks and kitchen police are also from the depot brigade, none of the "contacts" being allowed in the kitchens. Food is cooked here and carried by the men of the different groups to their tents to be eaten.

Mumps contacts, measles, meningitis carriers, meningitis contacts, tonsillitis, diphtheria, scarlet fever, and epidemic conjunctivitis contacts are all in separate groups and are not allowed to intermingle.

When the actual contacts can be ascertained, this arrangement will prevent whole companies from being quarantined, which has been the necessary and established procedure until this time.

SEARCH FOR CARRIERS

As an additional sanitary measure, cultures are being made from the throats of all men in the search for carriers. Enough men have been removed from all barracks where there are not 500 cubic feet of air per man to give the correct allowance. Beds are so arranged that the foot of one bed is opposite the head of the bed at the side of it, thus aiding in preventing droplet infection from sneezing or coughing at night. Beds must be at least 18 inches apart. An officer also inspects each barracks at midnight to see that a sufficient number of windows are opened.

DISEASE INCIDENCE

All of the diseases of the camp show a declining incidence, with the exception of measles, mumps and pneumonia. I am not permitted to give official figures.

HEALTH OF EXTRA CANTONMENT ZONE

The nearby towns of Junction City and Manhattan have become somewhat alarmed over the situation, as the result of rumors that have been fallaciously spread which are probably distorted accounts about the necessity of our sanitary precautions. They talked about quarantining soldiers from these towns, but finally reconsidered. All soldiers of the cantonment have already been prohibited by order from going to movies, attending church socials, or in any way congregating into large groups, among which may be carriers. Two cases of meningitis have developed in Manhattan and one in Junction City. As a precaution, the throats and noses of all workmen who live in these towns are being sprayed daily with dichloramin-T, the same treatment that is given the soldiers.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Nov. 23, 1917

1. Total strength of Troops in United States as reported....1,067,698
   Annual admission rate per 1,000 (disease only)........ 1,619.8
   Non-effective rate (all divisions)...................... 38.6
2. *National* Guard, strength (Divisions in United States) 403,573
   Annual admission rate per 1,000 all divisions (disease only) 1,732.9
   Non-effective rate all divisions (all causes) 44.5

Divisions showing admission rate for disease higher than average: Camps Bowie, Wheeler, Beauregard, Kearney, Sevier, Cody, Doniphan and Shelby.

Divisions showing *non-effective* rate all causes higher than average: Camps Bowie, Beauregard, Wheeler, Sevier, Kearney, Shelby, Cody and MacArthur.

3. National Army, strength (Divisions in United States)......426,310
   Admission rate per 1,000 all divisions (*disease only*).... 1,444.6
   Non-effective rate all divisions (all causes) 30.7

Divisions showing admission rate for disease higher than average: Camps Travis, Jackson, Funston, Pike, Dodge, Dix and Lewis.

Divisions showing non-effective rate all causes higher than average: *Camps Pike*, Funston, Jackson, Travis, Lewis and Dix.

4. Venereal Disease—
   Annual admission rate Regulars in United States........... 146.1
   Annual admission rate National Guard (Divisions in U. S.).. 68
   Annual admission rate *National* Army (Divisions of U. S.)... 69

National Guard Division having rate above average: Camps Doniphan, Bowie, Logan, Beauregard and Wheeler.

National Army Division having rate above average: Camps Jackson, Dix, Travis and Gordon.

5. Number of cases of pneumonia 616
   Highest number in any one division ....*(31st Division)* 150
   Number *of* cases of meningitis 77
   Highest number in any one division ....(89th Division) 20

6. NEW CASES OF SPECIAL DISEASES REPORTED DURING THE WEEK ENDING NOV. 23, 1917

To Tenafly, N. J., for duty, from Army Medical School, Lieut. BRYON D. WHITE, Brooklyn.

To his home and the inactive list, Capt. JOSEPH McDONALD, New York.

To his home and the inactive list on account of being physically disqualified for active service, from Camp Wheeler, Lieut. HENRY S. FRUITNIGHT, New York City.

To his home, from Camp Gordon, Lieut. CARLTON A. LEE, Brooklyn.

Honorably discharged, Capt. LOUIS HAUSWIRTH, New York City; Lieut. ALFRED BRAUN, New York City.

North Carolina

To Neurological Institute, New York, for instruction, Capt. EDWIN B. FEREBEE, Raleigh.

To New York City, Bellevue Hospital, for instruction and on completion of this course *to Rockefeller Institute,* for further instruction and on completion *to Camp Sheridan,* base hospital, Capt. EVERETT A. LOCKETT, Winston-Salem.

To report by wire to the commanding general, Southeastern Dept., from Chickamauga Park, Lieuts. LOUIS H. WEBB, Chapel Hill; NEWTON G. WILSON, Summerfield.

North Dakota

To Camp Beauregard, Alexandria, La., base hospital, from Fort Riley, Lieut. GEORGE V. JAMIESON, Devils Lake.

To Camp Shelby, Hattiesburg, Miss., base hospital, from Fort Riley, Lieut. JOHNSTON C. JACKMAN, Minot.

To Fort Riley, Kan., base hospital, from Fort Riley, Lieut. ADOLPH G. MAERCKLEIN, Ellendale.

To Montgomery, Ala., Aviation Mobilization Camp, for duty, from Fort Riley, Lieut. HIRAM LaM. YOUTZ, Willow City.

To New York City, Neurological Institute, for intensive training in brain surgery, from Fort Benjamin Harrison, Capt. JAMES P. AYLEN, Fargo.

Ohio

To Camp Dix, Wrightstown, N. J., for duty, from Fort Benjamin Harrison, Lieut. SAMUEL J. ELLISON, West Union.

To Camp Dodge, Des Moines, Ia., base hospital, from Fort Oglethorpe, Lieut. ROBERT R. SATTLER, Cincinnati; *from* Fort Benjamin Harrison, Lieut. RALPH W. FAUS, Wellington.

To Camp Grant, Rockford, Ill., for duty, from Fort Benjamin Harrison, Lieut. EDWIN G. SCHWARZ, Cleveland.

To Camp Jackson, Columbia, S. C., for duty, from New York City, Lieut. GEORGE B. BOOTH, Toledo.

To Camp Sevier, Greenville, S. C., for duty, from Fort Benjamin Harrison, Lieut. ARTHUR W. CARLEY, Dayton.

To Fort Oglethorpe, Ga., for a course of instruction, from Camp Cody, Lieuts. FRANK E. SNIDER, Madisonville; from Post Graduate Hospital, New York City, BARNEY J. HEIN, Toledo.

To Fort Riley, Kan., for a course of instruction, Lieut. FRED L. ANDREWS, Cleveland.

To Oklahoma City, Okla., for a course *of instruction* in orthopedic surgery, Lieut. ZALMON O. SHERWOOD, Geneva.

To Philadelphia, Evans Dental Institute, for a course of instruction and upon completion of this course to return to his proper station, from Columbus Barracks, Capt. GEORGE C. SCHAEFFER, Columbus.

To Washington, D. C., for duty as pharmacologist at the American University, from Gas School, Fort Sill, Ark., Capt. JAMES D. PILCHER, Cleveland; to Government Hospital for Insane, for duty, from Army General Hospital, No. 1 Capt. WILLIAM A. SEARL, Cuyahoga Falls.

To his home and honorably discharged from the Medical Reserve Corps, on account of being physically disqualified for active service, from Camp Wadsworth, Lieut. CHARLES C. MANDEVILLE, Galion.

To his home and relieved from further active duty in the Medical Reserve Corps, from Fort Des Moines, Lieut. LOUIS A. CORNISH, Cincinnati.

Honorably discharged from the Medical Reserve Corps on account of being physically disqualified for active service, Lieut. JERRARD W. COOMBS, Camden.

Oklahoma

To Fort Riley, Kan., base hospital, from Fort Riley, Lieut. CHARLES C. GARDNER, Ashland.

To Hoboken, N. J., for duty, from Fort Oglethorpe, Lieut. THOMAS M. BOYD, Norman.

To Montgomery, Ala., Aviation Mobilization Camp, for duty, from Fort Oglethorpe, Lieut. JAMES R. BOST, Cashion.

To Portland, Oregon, for assignment to duty with aero squadrons, from Fort Riley, Lieuts. FRANK R. BUCHANAN, Canton; PENDELTON GARDNER, Haileyville.

To Camp Travis, Fort Sam Houston, Tex., base hospital, Lieut. ARTHUR T. BLACHLY, Portland.

To Hoboken, N. J., for duty, from Fort Oglethorpe, Lieut. LEONARD M. VINCENT, Crane.

Pennsylvania

To Army Medical School, Washington, D. C., bacteriologic laboratory, from Fort Benjamin Harrison, Lieut. SOLOMON F. HOGE, Philadelphia.

To Camp Custer, Battle Creek, Mich., for duty, from Fort Benjamin Harrison, Lieut. HENRY B. INGLE, Bedford Springs.

To Camp Greene, Charlotte, N. C., for duty with Headquarters Military Police, from Camp Greenleaf, Lieut. JOSEPH J. AUSTRA, Philadelphia.

To Camp Greenleaf, Fort Oglethorpe, for instruction, Lieut. JAMES C. McCONAUGHEY, Wayne.

To Camp Lee, Petersburg, Va., base hospital, from University of Pennsylvania, Lieut. FREDERICK J. GARLICK, Philadelphia.

To Camp Logan, Houston, Tex., base hospital, from Orthopedic Hospital, New York, Lieut. RALPH L. RUTLEDGE, McKeesport.

To Camp Meade, base hospital, Capt. EDWARD McI. HALEY, Blossburg.

To Camp Mills, Garden City, L. I., base hospital, from New York, Lieut. JOHN W. FREY, Ovalon.

To Camp Sherman, base hospital, Lieut. LAWRENCE H. FITZGERALD, Pittsburgh.

To Camp Taylor, Louisville, Ky., for duty, from Fort Oglethorpe, Lieut. CLARENCE H. KETTERER, Butler.

To Camp Travis, Fort Sam Houston, Tex., for duty, from Fort Oglethorpe, Lieut. DeWITT B. NETTLETON, Sewickley.

To Camp Wheeler, Macon, Ga., *base hospital*, Major *JOSEPH* SAILOR, Philadelphia; from Fort Benjamin Harrison, Lieuts. JAMES B. CARROLL, Dunbar; REEVES W. DeCROW, Collegeville; from Atlanta, Ga., Lieut. RUBEN A. E. PETERSON, Allentown; from Fort Oglethorpe, Lieuts. THOMAS W. DRUCE, Philadelphia; FRANCIS E. DONNELLY, Wilkes-Barre, from Camp Shelby, Hattiesburg, Miss.; Lieut. JOHN H. MUSSER, Jr., Philadelphia.

To El Paso, Tex., for duty, with Ambulance Co. No. 1, from Chickamauga Park, Ga., Lieut. HUGH M. SHANNON, Philadelphia.

To Fort Oglethorpe, for instruction, from Camp Meade, Lieut. JOHN W. MANN, Pittsburgh.

To Fort Riley, Kan., for instruction, Lieut. BENJAMIN ROBINSON, Philadelphia.

To Garden City, L. I., N. Y., for duty, Major WALTER S. CORNELL, Philadelphia.

To Montgomery, Ala., Aviation Mobilization Camp, for duty, from Fort Oglethorpe, Lieut. ALBON E. FICHTNER, Johnston.

To Hoboken, N. J., for duty, from Fort Oglethorpe, Lieut. HARRY M. READ, York.

To Newport News, Va., for duty at Camp Stuart, from Camp Greenleaf, Lieut. FRANK D. CAMPBELL, Slippery Rock.

To Philadelphia, Pa., for duty with base hospital No. 20, Major GEORGE M. PIERSOL, Philadelphia; *to Evans Dental Institute*, for instruction, and on completion *to Wrightstown, N. J.*, base hospital, Major GEORGE M. DORRANCE, Philadelphia; for duty, from Neurological School, University of Pennsylvania, Capt. JOHN LOWMAN, Johnstown; *to Evans Dental Institute*, for instruction, Lieuts. HARRY S. CARMANY, HAROLD A. FLETCHER, Philadelphia; *to Jefferson Hospital* for duty, from Neurological School, University of Pennsylvania, Lieut. GUY M. MUSSER, Punxsutawney.

To Walter Reed General Hospital, Takoma Park, D. C., for temporary duty, from Camp Meade, Lieut. JAMES H. BALDWIN, Philadelphia.

To Williams Bridge, N. Y., United States General Hospital, No. 1, for temporary duty, from New York Orthopedic Hospital, Lieut. JAMES L. GILMORE, Pittsburgh.

To Pittsburgh, Pa., for instruction in military roentgenology, from Fort Oglethorpe, Capt. JOHN J. McKENNA, Philadelphia; Lieut. PATRICK J. O'DEA, Scranton.

To Rockefeller Institute, for instruction in the therapy of pneumonia, Lieut. CLIFFORD C. HARTMAN, Pittsburgh; for instruction and on completion to his proper station, from Camp Hancock, Lieut. WILLIAM N. PARKINSON, Philadelphia.

To his home and honorably discharged on account of being physically disqualified for active service, from Newport News, Va., Lieut. FREDERICK W. KNIPPEL, Mercer.

South Carolina

To Camp Greene, Charlotte, N. C., for duty with the Headquarters Military Police, from Camp Greenleaf, Lieut. ISAAC H. GRIMBALL, Ridgeland.

To Camp Robinson, Sparta, Wis., for duty, from Fort Oglethorpe, Capt. THEODORE C. STONE, Aiken.

South Dakota

To Fort Sill, Okla., base hospital, from Camp Pike, Capt. THOMAS W. MOFFITT, Deadwood.

To Portland, Ore., for assignment to duty with aero squadrons, from Fort Riley, Lieut. FRANCIS T. READ, South Shore.

Tennessee

To Army Medical School, Washington, D. C., for instruction in orthopedic surgery, Capt. Alphonse *H.* Meyer, *Memphis*.

To Camp Gordon, Atlanta, Ga., as member of board for examination of command for tuberculosis, from Fort Oglethorpe, Lieut. ENOCH S. SEALE, Nashville.

To Camp Greene, Charlotte, N. C., for duty, from Fort Oglethorpe, Lieut. CURTIS R. SENTER, *Memphis*.

To Fort McPherson, Ga., base hospital, from Camp Greenleaf, Lieut. CHARLES D. BLASSINGAME, Memphis.

To Fort Myer, Va., from Camp Meade, Lieut. ALLEN L. LEAR, Sewanee.

To Fort Oglethorpe, Ga., for duty with Field Hospital No. 3, from Fort Oglethorpe, Lieut. LOUIS F. VERDEL, *Memphis*.

To Oklahoma City, Okla., for instruction in orthopedic surgery, from Fort Oglethorpe, Lieut. BENJAMIN L. SCHOOLFIELD, Memphis.

To Walter Reed General Hospital, Takoma Park, D. C., for duty in connection with the Mobile Operating Unit, from Army Medical School, Lieut. PAUL E. McNABB, Knoxville.

Texas

To Camp Logan, Houston, Tex., for duty with the Headquarters Military Police, from Camp Greenleaf, Lieut. PIERRE F. HIGGINS, Fort Worth.

To Camp Meade, Annapolis Junction, Md., for duty, from Fort *Oglethorpe*, Lieut. KARL CHAMBERS, Jasper.

To Fort Oglethorpe, Ga., for instruction, from Camp Cody, Lieuts. HENRY BRADBROOK, Cat Spring; ROBINSON H. SALMON, Maypearl.

To Oklahoma City, Okla., for instruction in orthopedic surgery, from Camp Fort Bliss, Lieut. FREDERICK E. HUDSON, Anson.

Virginia

To Camp Jackson, Columbia, S. C., for duty, from Fort Oglethorpe, Lieut. BERNARD BARROW, Barrows Store.

To Philadelphia, Pa., Evans Dental Institute, for instruction, Lieuts. LEWIS G. RICHARDS, *Roanoke*; from Fort Oglethorpe, JOHN B. HALLIGAN, Petersburg; for instruction and on completion *to his proper station*, from Fort Myer, Lieut. MINOR G. LILE, University.

To report by wire to the commanding general Southeastern Dept. from Chickamauga Park, Lieut. JAMES C. MOTLEY, Abingdon.

To his home and the inactive list on account of being physically disqualified for active service, Lieut. GRANVILLE EASTHAM, Rapidan.

Washington

To Camp Lewis, American Lake, Wash., base hospital, Lieuts. HIRAM S. ARGUS, EDWIN A. MONTAGUE, HARRY G. WILLARD, Tacoma.

To Camp Mills, Garden City, L. I., for duty, Lieut. IVAN J. D. SHULER, Seattle.

West Virginia

To Camp Cody, Deming, N. M., base hospital, from Camp Cody, Capt. LEWIS C. COVINGTON, Charleston.

To Camp Greene, Charlotte, N. C., for duty as assistant to the Division Surgeon, from Camp *Greenleaf*, Lieut. WILLIAM H. *McLAIN*, Wheeling.

To Camp McClellan, Anniston, Ala., for duty with Headquarters *Military Police, from Camp Greenleaf, Lieut.* WILLIAM NELSON, Hansford; from Fort Benjamin Harrison, Lieut. ADLAI E. CALLAHAN, Parkersburg.

Wisconsin

To Camp Beauregard, Alexandria, La., base hospital, from Fort Riley, Lieut. EMIL A. RUKA, Bascobel.

To Camp Grant, Rockford, Ill., base hospital, from Fort Benjamin Harrison, Lieut. ARTHUR C. DANA, Fond du Lac.

To Camp Jackson, Columbia, S. C., as member of board for examination of command for tuberculosis, from Camp Sheridan, Capt. MICHAEL R. WILKINSON, *Oconomowoc*; Lieut. HARRY C. MIX, *Green Bay*.

To Fort Riley, Kan., for duty, from Fort Riley, Lieut. GERHARD A. BADING, Milwaukee.

To Fort Sheridan, Ill., for duty, from Fort Benjamin Harrison, Major OTHO A. FIEDLER, Sheboygan.

To Montgomery, Ala., Aviation Mobilization Camp, for duty, from Fort Riley, Lieuts. RAYMOND A. HEBRON, Cataract; ALBERT H. KULIG, Dodge; CHARLES M. PEARSON, *Ogema*; EDWARD P. EVANS, S. Milwaukee; ATHOL H. WEDGE, Waupun.

To Newport News, Va., for duty at Camp Stuart, from Camp *Greenleaf*, Lieut. *GEORGE H.* SCHLENKER, Cazenovia.

To New York City, Neurological Institute, for intensive training from Psychopathic Hospital, Boston, Mass., Lieut. CHARLES *C.* ROWLEY, Winnebago.

To Portland, Ore., for assignment to duty with aero squadrons, from Fort Riley, Lieuts. DONALD G. HUGO, Chilton; HIRAM A. FULTON, Eau Claire; REUBEN J. ELLIOT, National Home; LESLIE A. VAN DER LINDE, Wautoma.

To his home and to report by wire to the Surgeon-General from Camp MacArthur, Lieut. *JAMES GURNEY* TAYLOR, *Milwaukee*.

To the inactive list, from University of Pennsylvania, Lieut. ORVILLE R. LILLIE, Milwaukee.

CORRECTIONS

Attention is called to the following corrections in previous lists of orders to medical officers:

In the issue of October 6: *To Fort Benjamin Harrison* for *instruction*, CHARLES A. ROBERTSON of Hopkinsville, Ky., instead of C. A. Robertson of Ridgetop, Tenn.

In the issue of November 24: *To Camp Cody*, base hospital, from Fort Benjamin Harrison, Lieut. ELMER E. JOHNSON, Philadelphia, instead of Elmer S. Johnson, Oregon, Wis.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ILLINOIS

Pneumonia Quarantine Ordered.—The health commissioner of Chicago issued a notice, November 25, to the effect that "Pneumonia is a contagious disease and under city ordinances must be reported to the Department of Health. Beginning December 1, the Commissioner of Health will placard all reported cases of pneumonia."

Personal.—Col. William Stephenson, M. C., U. S. Army, department surgeon, Central Department, has been transferred to a similar position in the Eastern Department, with station at Governor's Island, N. Y.——Col. Henry I. Raymond, M. C., U. S. Army, Fort Mason, Calif., has succeeded Colonel Stephenson as department surgeon, Central Department.——Dean Arthur I. Kendall of Northwestern University Medical School, Chicago, delivered an address on "Recent Development in Intestinal Bacteriology," before the Philadelphia Pathological Society, November 2.

Clinical Conference on Tuberculosis.—The first clinical conference on the early diagnosis of tuberculosis under the auspices of the State Council of Defense, the State Department of Public Health and the Illinois Tuberculosis Association, constituting the Cooperating Committee on the Tuberculosis War Problem of Illinois, was held at Springfield, November 22-24. This conference was attended by thirty physicians, each delegated as county medical director on tuberculosis from his respective county. The clinical work was carried out in the dispensary of the Springfield Tuberculosis Association, the Springfield Open Air Colony, St. John's Hospital and the laboratory of the State Department of Public Health by Dr. Orville W. McMichael and Dr. Ethan Allen Gray, Chicago, Dr. James Pettit, Ottawa, and Dr. George Thomas Palmer, Springfield. This is the first of several conferences provided for in the Illinois tuberculosis war program, to provide one physician proficient in the diagnosis and treatment of tuberculosis in each county to meet the war time needs of the military and civil population.

INDIANA

New Hospital.—A contagious disease hospital is to be built as a separate unit of the Indianapolis City Hospital at a cost of $90,000. The plans call for the construction of a two-story brick and concrete building.

Smallpox Epidemic.—An epidemic of smallpox is reported to prevail in Fort Wayne, where there are now more than 200 cases. In addition there are forty-three cases in Grabill, New Haven, Huntertown, Allen and Aboite.

New Medical School.—The University of Notre Dame has established a medical department, which is offering the first two years of the medical course. Two years of college work are required for admission, constituting, with the two medical years, the first four years of the six-year combined course for the baccalaureate and M.D. degrees.

KENTUCKY

Hospital for Insane Burns.—The building for tuberculous patients at the State Hospital for the Insane, Lakeland, was destroyed by fire, November 26.

Personal.—Dr. Henry Enos Tuley, dean of the Medical Department of the University of Louisville, has accepted the appointment of superintendent of Louisville's new City Hospital from Mayor Smith.——Dr. A. E. Ferguson, Austin, has been appointed a member of the State Tuberculosis Board, succeeding Dr. Richard T. Yoe, Louisville, term expired.——Dr. W. Lucien Heizer, Bowling Green, secretary of the State Tuberculosis Commission, and formerly State Registrar of Vital Statistics, is ill with diphtheria at his home in Bowling Green.

MARYLAND

Personal.—Dr. Harry S. Jarrett, Towson, who has been under treatment at the Mercy Hospital, Baltimore, has returned home, and his condition is much improved.——Dr. Lewellys F. Barker of the Johns Hopkins Hospital delivered a lecture, illustrated by lantern slides, at the New York Academy of Medicine, December 7, on "The General Diagnostic Study by the Internist."

Dental and Medical Affiliation.—The first joint meeting of the Maryland State Dental Association and the Baltimore City Medical Society took place at Osler Hall, Baltimore, November 30. Dr. Weston A. Price, Cleveland, director of the National Institute of Dental Research, addressed the meeting on "Some Studies on the Relationship Between Oral Focal Infections and Localized and Systemic Diseases."——A recent affiliation has been effected between the Medical and Chirurgical Faculty of Maryland and the State Dental Association, whereby the dentists have become members of the faculty. A dental library is being collected.

MICHIGAN

New Hospital for Marquette.—A contagious disease hospital, to cost $10,000, will be erected by the St. Luke's Hospital Association in Marquette.

Tri-County Sanatorium Planned.—A meeting was held at Grand Haven, November 8, at which the question of erecting a tuberculosis sanatorium to be used jointly by Muskegon, Ottawa and Allegan counties was discussed. It is believed that a tri-county sanatorium can be much more economically administered than a separate institution for each county.

Personal.—Dr. Bartlett H. McMullen, mayor of Cadillac, underwent an operation recently in Rochester, Minn., for disease of the jaw, and is reported to be doing well.——Dr. James W. Inches, health officer of Detroit, who has been on duty in France, expects soon to return on leave.——Dr. George M. Belhumeur, Negaunee, has been appointed chief of the Kimbley Clark Company at Niagara, Wis.

MINNESOTA

Fellowships in University.—Fellowships in medicine, surgery, nervous and mental diseases, ophthalmology and otolaryngology are available at the University of Minnesota, under annual stipends in the three-year course, respectively, of $500, $750 and $1,000.

Society Organizes.—Thirteen members of the medical profession of Stillwater and Washington counties met at Stillwater, November 19, and reorganized the Washington County Medical Society, electing the following officers: president, Wade R. Humphrey; vice presidents, Drs. Gustavus A. Newman and Burton J. Merrill, and secretary-treasurer, Dr. Frank G. Landeen, all of Stillwater.

Personal.—Dr. Marion M. Hursh, Grand Rapids, is remodeling the parsonage of the Methodist Church, and will use it as an office and hospital.——Dr. Donald E. Baxter, Minneapolis, sailed for France, November 23, to take charge of the reconstruction of the Children's Hospital under the general war board.——Dr. Richard O. Beard of the College of Medicine of the University of Minnesota, Minneapolis, was the principal speaker at a mass meeting of citizens of Willmar and Kandiyohi counties to exploit the establishment of a general hospital.

Southern Minnesota Physicians Meet.—The annual meeting of the Southern Minnesota Medical Society was held in Mankato, November 26 and 27, under the presidency of Dr. Aaron F. Schmitt, Mankato. Addresses were delivered by Col. Henry S. Greenleaf, M. C., U. S. Army, Fort Snelling; Major William J. Mayo, Rochester; Lieut. Edward W. Ryerson, Chicago, and others. The following officers were elected: president, Dr. Melvin S. Henderson, Rochester; vice presidents, Drs. Alphonse E. J. Sohmer, Mankato, and Peter F. Holm, Wells, and secretary-treasurer, Dr. George F. Merritt, St. Peter.

Hospital News.—At a meeting of the Commercial Club, held in Rice Lake, November 14, resolutions were passed favoring the erection of a hospital to cost $9,500.——A thoroughly modern and well-equipped hospital building, with accommodation for twelve or fourteen patients, is to be erected in Appleton, in the spring. About $5,000 has already been subscribed for the enterprise.——The West Cottage at the Glen Lake Sanatorium was formally opened by the Hennepin County Sanatorium Commission, November 24. The opening of this cottage provides forty-four additional beds for the sanatorium, making a total of 104 beds.

MISSOURI

Personal.—Dr. Oscar J. Raeder, assistant superintendent of the City Sanitarium, St. Louis, has resigned his position to study neuropathology at the Boston Psychopathic Hospital;

under Elmer E. Southard.——Dr. John J. Evans, Manes, being compelled by a paralytic stroke to retire from practice, has been elected an honorary member of the Wright County Medical Society.

Hughes Brothers Convicted.—Drs. Ulysses S. G. Hughes and John H. Hughes, Kansas City, charged in the federal court with illegal drug selling, and convicted, are said to have been sentenced, November 19, to four years' imprisonment in the Federal Penitentiary, Leavenworth. One brother was convicted on eleven counts, and the other on nineteen, and both are said to have been previously convicted on the violation of the Harrison Narcotic Law, in the federal court in Kansas.

NEW YORK

State Troopers Aid in Maintaining Quarantine.—An outbreak of smallpox in the Cattaraugus Indian Reservation recently made it necessary to quarantine the entire reservation. Owing to the size of the reservation a detail of state troopers were despatched to the reservation on the request of the state health department. They effectively surrounded the reservation and maintained a satisfactory quarantine.

New York City

Harvey Society Lecture.—The fourth lecture of the Harvey Society series, delivered at the New York Academy of Medicine, December 8, was by Prof. Aldred S. Warthin, M.D., of the University of Michigan, Ann Arbor, on "The New Pathology of Syphilis."

New Section Hospital.—Dr. Henry Fairfield Osborn, president of the American Museum of Natural History, in cooperation with H. F. Beers, superintendent of construction of the museum, has designed a field hospital suitable for use in the army, and in Red Cross and general hospital work. The hospital is constructed in 5-foot units so that it can be taken apart and reconstructed by unskilled labor, and can be easily transported. The device can also be converted into a dwelling house. A large model is on exhibition at the American Museum of Natural History.

Personal.—Dr. James P. Warbasse, Brooklyn, has been elected president of a newly organized body known as the Consumers' Cooperative Society, the object of which is to arouse trades unions and consumers in general in a plan for the establishment of cooperative stores which will do away with the middleman's profit.——Dr. and Mrs. Simon Baruch celebrated their fiftieth wedding anniversary, November 27, by a reception at Sherry's, at which more than 1,000 guests were present.——Dr. William Seaman Bainbridge has had the degree of LL.D. conferred on him by the trustees of Lincoln Memorial University. Dr. Bainbridge is about to sail for foreign service.——Dr. Abraham Stone, Williamsburg, narrowly escaped death by gas asphyxiation in his home, November 20.

Annual Meeting of County Medical Society.—The one hundred and twelfth annual meeting of the Medical Society of the County of New York was held on the evening of November 25. Resolutions were passed for presentation to Congress aiming at the repeal of Section 209 of the excess profit tax, which imposes a tax of 8 per cent. on all incomes over $6,000 per annum derived from labor. It was pointed out that this law worked a great injustice to medical men in that they were not only taxed for working but any time they entered the service their income from the practice of medicine stopped altogether. The following officers were elected: president, Dr. Howard C. Taylor; vice presidents, Drs. Charles H. Peck and Samuel A. Brown; secretary, Dr. Daniel S. Dougherty; assistant secretary, Dr. J. Milton Mabbott, and treasurer, Dr. James Pedersen.

Two Committees Working for New Drug Laws.—November 28, two conferences were held in this city for the discussion of ways and means of controlling the traffic in habit-forming drugs. One of these committees was the Whitney Legislative Committee. This committee has decided to make a thorough investigation of the drug evil as it exists in this city at the present time. Beginning December 5, it will hold a series of hearings at which it will take testimony in regard to various phases of the drug traffic. What the committee desires to accomplish is to put the law in such shape as to prevent future addiction and to cure as many of the present addicts as possible. The other committee which met at the same time was the New York City Committee of Drug Evils. The members of this committee agreed that what was most needed was federal control of the traffic in narcotic drugs of a definite and comprehensive sort. The statement was made by Dr. Campbell, physician in charge of the Harlem Prison, that there were from 10,000 to 15,000 young men in New York City who were drug addicts and in need of some compulsory form of treatment. A bill was submitted for the consideration of this committee which provides that the government shall destrict the sale and manufacture of narcotic drugs through the imposition of a tax which would tend to make the distribution of drugs prohibitive for any but legitimate purposes.

PENNSYLVANIA

Personal.—Major John A. Hawkins, M. R. C., U. S. Army, Pittsburgh, who is now stationed at Allentown, was presented, November 22, with a fund of more than $4,500 for the equipment of the ambulance companies under his command.——Dr. John J. Coffman, Scotland, has resigned after eighteen years of service as secretary of the Franklin County Medical Society.——Dr. Samuel G. Dixon, state commissioner of health, who has been ill in the Pennsylvania State Hospital, Philadelphia, is reported to be convalescent.

Philadelphia

Baby Clinic Opened.—A baby clinic in charge of Dr. Lida Stewart-Cogill was opened yesterday at the Women's College Hospital. Instructions will be given to mothers daily.

Women Doctors Needed for Army.—According to Dr. Emily Dunning Barringer, New York, vice chairman of the Medical Women's National Association, who spoke at the meeting of the Women's Hospital Medical Society, in the Women's Medical College Hospital, November 21, twelve women physicians who are physically, morally and mentally fit are needed to serve with the American Army. The women who volunteer must be able to speak French.

Personal.—Dr. Edwin B. Cragin, professor of obstetrics and gynecology at Columbia University, New York, addressed the Obstetrical Society of Philadelphia at the College of Physicians, December 6, on "The Functions of a Woman's Hospital in a Large City," and was the guest of honor at a reception held at the Rittenhouse Hotel immediately following the meeting.——Dr. Charles S. Turnbull has been reappointed a member of the board of managers of the State Institution for Training of Deaf Children.——Dr. Robert C. Barrett has been elected acting roentgenologist to the Orthopedic Hospital during the absence of Dr. Ralph S. Bromer on military service.

RHODE ISLAND

Mass Meeting for Nurses.—November 11, a mass meeting was held in the Rhode Island State Medical Society Building, Providence, under the auspices of the Rhode Island Association of Graduate Nurses, to interest nurses in enrolling for home service in cantonment hospitals. Dr. G. Alder Blumer, Providence, presided.

Personal.—Dr. Frank A. Fearney, Narragansett Pier, has been appointed medical examiner (coroner) for the town of Narragansett, to succeed Lieut. Malford W. Thewlis, M. R. C., U. S. Army, resigned to enter military service.——Dr. Ransom H. Sartwell has been appointed resident physician to state penal institutions, with the exception of the almshouse, and the Exeter School for the Feebleminded.

WASHINGTON

Personal.—Dr. William F. West has been appointed a member of the board of health of Everett, succeeding Dr. John F. Beatty, resigned on appointment as health officer. ——Dr. Leon G. Woodford has resigned as city health officer of Everett to accept a position of superintendent and physician in charge of the Snohomish County Tuberculosis Sanatorium, Aldercrest.——Dr. Jarrett H. Farrell, Spokane, has been appointed bailiff in the court of Superior Judge Oswold.——Dr. Edward B. Nelson has been elected president, Dr. Foster M. Hoag, vice president, and Dr. I. Rebecca L. Muir, secretary-treasurer of the staff of the Deaconess Hospital, Spokane.

WISCONSIN

Campaign for Hospital.—The campaign to raise $500,000 for Columbia Hospital, Milwaukee, was opened, November 20, at a meeting and banquet held in the Hotel Pfister, and John G. Bowman was the chief speaker of the evening.

Personal.—Dr. Frederick M. Harris, formerly health officer of Fond du Lac and director of the state cooperative laboratory at St. Agnes Hospital, has resigned to enter private practice.——Dr. Frederick C. Christensen, Racine, underwent operation for appendicitis, November 17, and is reported to be doing well.——Dr. George N. Hidershide, Arcadia, is seriously ill with pneumonia.——Dr. Hugh P. Greeley, Waukesha, has gone to New York to take up special research work at the Rockefeller Institute.

Sanatorium Notes.—After listening to the plea of Dr. Fred T. Nye, Beloit, for the establishment of a sanatorium for Rock County, the county board, November 16, postponed action until the January meeting of the board.——The Ashland County Board, by unanimous vote, November 16, adopted the resolution favoring a tuberculosis sanatorium, and made an appropriation of $40,000 toward the erection of a building, with the provision that Bayfield and Iron counties aid in the project.——The board of supervisors of LaCrosse County, November 15, made an appropriation of $15,000 to complete the LaCrosse County Tuberculosis Sanatorium, which will be ready for occupancy in the spring.

CANADA

Hospital Burns.—The Hotel Dieu War Hospital at Ste. Hyacinthe, Que., was destroyed by fire, November 28. The patients, 1,000 in number, were removed in safety.

Diphtheria Death Rate Lowered.—During November the death rate from diphtheria has materially lessened in the province of Ontario. In fact, it dropped to the lowest figure in the history of the province. During the month in 1917 there were 432 cases reported, with sixteen deaths, as against 467 cases in the same month in 1916, with twenty-eight deaths. The health officials state that in the month free antitoxin was distributed at a cost of $3,907 which has no doubt brought about the low death rate from that disease. Infantile paralysis has almost disappeared from the province.

Personal.—Col. Harry M. Jacques, Toronto, medicals overseas, was invested with the Distinguished Service Order at Buckingham Palace, Nov. 29, 1917.——Lieut.-Col. Herbert S. Birkett, dean of the medical faculty of McGill University, Montreal, who has been overseas two years in command of McGill University Base Hospital, has resigned on account of continued illness. Lieut.-Col. John M. Elder, Montreal, has taken over the command.——Dr. Howard A. Kelly, Baltimore, visited Guelph, Ont., November 30. He was the guest of Dr. Alfred T. Hobbs of the Homewood Sanitarium. Dr. Kelly held a surgical clinic at the General Hospital, performed two or three operations, and gave an illustrated lecture on the use of radium in the treatment of disease. He was banqueted by the physicians of Guelph, and in the evening addressed the two Canadian clubs on "The Civic Duty of the Christian Citizen."

GENERAL

Roentgenologists to Meet.—The fourth annual midwinter meeting of roentgenologists will be held at the Hotel Traymore, Atlantic City, Friday evening and Saturday, Jan. 4 and 5, 1918, to which all physicians interested are invited.

Tri-State Physicians Meet.—The forty-fourth annual meeting of the Tri-State Medical Society of Indiana, Ohio and Michigan was held in LaPorte, Ind., November 21, under the presidency of Dr. Miles F. Porter, Fort Wayne, Ind. At the banquet in the evening, Dr. Frank R. Leeds, Michigan City, Ind., presided as toastmaster, and addresses were delivered by Rev. C. B. Moulinier, S. J., Regent of Marquette University, Milwaukee, Wis., on "Necessity of Standardizing Hospitals"; by Albert J. Ochsner, Chicago, on "After Treatment of a Surgical Case," and by Dr. Frank Billings, Chicago, on "Russia as Observed by the Red Cross Commission." The following officers were elected: president, Dr. Julius H. Jacobson, Toledo, Ohio; vice president, Dr. George V. Brown, Detroit; secretary, Dr. George W. Spohn, Elkhart, Ind. (reelected), and treasurer, Dr. Harry F. Mitchell, South Bend, Ind. (reelected). Detroit was selected as the place of meeting for 1918.

Bequests and Donations.—The following bequests and donations have recently been announced:

Hospital for Crippled and Deformed Children; Rosewood State Training School, Owings Mills, Md.; Presbyterian Eye, Ear and Throat Hospital; Provident Southern Hospital, and Maternité Hospital, Baltimore, each $2,000, by the will of Ferdinand Dietsch.

New York Post-Graduate Hospital, $1,000, the proceeds of a benefit, for the use of a babies' ward.

Adirondack Cottage Sanatorium, Saranac, N. Y., one-half the residuary estate of Robert W. Patterson, which is valued at about $1,000,000.

Lakeside Hospital, Cleveland, $1,000,000, and St. Vincent's Charity Hospital, Cleveland, $200,000, by the will of Oliver H. Payne, New York.

Alumni Association of the Jefferson Medical College, an ultimate bequest of $10,000, to become operative on the death of his widow, and to be known as a memorial to his widow and mother, by the will of Dr. Joseph M. Malatesta.

Lankenau Hospital, Philadelphia, a donation of a building fully equipped and valued at $60,000, by Charles A. Smith; cash contributions of $8,000, and a donation from the alumnae of the nurses' school of $5,000 for a free bed for nurses.

St. Agnes Hospital, Philadelphia, cash donations of $1,700 on donation day.

Trade Commission Acts on Salvarsan Patent.—The Federal Trade Commission has entered orders for licenses to three firms to manufacture and sell arsphenamine, the product heretofore known under the trade name of salvarsan, patent rights to which have been held by German subjects. The orders for licensees are subject to acceptance and agreement by the licenses to the stipulations made by the commission. On such acceptance and agreement, these licenses will be formally granted by Secretary L. L. Bracken, acting for the commission. The three firms licensed to manufacture and sell arsphenamine are Dermatological Research Laboratories of Philadelphia; Takamine Laboratory, Inc., of New York, and Herman A. Metz Laboratory of New York. While the price of the product is not at this time fixed by the commission, the right to fix prices is retained, and a price of $1 per dose to the Army and Navy, $1.25 per dose for hospitals, and $1.50 per dose for physicians, are the prices at which some, at least, of the licensees have stated that they intend to offer the licensed drug. The trade commission's action was taken under Section 10 of the Trading With the Enemy Act under direction of Commissioner Fort, on recommendation of C. H. McDonald, Edward S. Rogers and Francis Phelps, in charge of granting such licenses. The Public Health Service has prepared rules and standards for the manufacture and testing of arsphenamine, and will supervise its manufacture, authority having been conferred on the Public Health Service by the Secretary of the Treasury, and the observance of the rules and standards become a condition of the license.

FOREIGN

Sixty Years of Medical Practice.—The profession in Holland recently celebrated the sixtieth anniversary of the entrance into practice of one of their leading physicians, R. Krul of 's-Gravenhage. He has published a number of works on medical history and other subjects. His first work, in 1881, was on the evils of quackery.

Deaths in the Profession Abroad.—Rt. Hon. Sir **Leander Starr Jameson**, Bart., M.R.C.S. (Eng.); M.B., B.S. (Lond.), 1875; L.S.A. (Lond.), 1876; M.D., University of London, 1877; aged 64; formerly of Kimberly, South Africa; who as Dr. Jameson led the raid from Cape Colony into the Transvaal in 1895; died at his home in London, November 28. Dr. Jameson began his South African career as administrator of Rhodesia, British South Africa in 1891; four years later he led the raid into the Transvaal, took part in the battle of Kugersdorp, and surrendered to the Boers, the whole transaction occupying only four days. After his release he was indicted and tried in London, and sentenced to imprisonment for ten months, but was released after seven months on account of ill health. He returned to South Africa, and in 1900 was elected member of the Cape Legislative Assembly for Kimberly. In the same year he was appointed director of the DeBeers Consolidated Company, and two years later of the British South African Company. In 1904 he was made Premier of Cape Colony and served in this capacity until his retirement. Then he returned to London.——**A. Ballori**, a prominent alienist of Rome, aged 70, was recently killed by a homicidal paranoiac. He escaped a similar attack made by a patient, a few years ago, when one of the nurses sprang in front of the physician and received the fatal injury.——**J. Peyrot**, agrégé professor of surgery at the University of Paris and senator, aged 74.——**F. C. Barraza**, professor of organic chemistry at the University of Buenos Aires, and assistant professor of ophthalmology, aged about 55.

British Minister of Public Health.—Our London correspondent has from time to time referred to the proposition of creating a minister of public health, which means a position in the cabinet. According to an Associated Press dispatch for December 4, this has culminated in the appointment of Sir Christopher Addison, M. P., minister of reconstruction, to this position. According to the newspapers, he "hopes to carry a bill through parliament before Christmas forming a new ministry to operate a scheme of 'revolutionary character.'

This scheme is said to aim at the nationalization of the medical profession, involving free medical attendance for every one without charge. Premier Lloyd George, the *Express* adds, says the time is ripe for such a change." Sir Christopher Addison has been in the public eye for many years. He graduated from the University of London in 1893; he has been lecturer on anatomy at St. Bartholomew's Hospital; examiner of anatomy in the Universities of Cambridge and London; a member of the Faculty of Medicine, chairman of the Board of Intermediate Medical Study, and member of the Board of Human Anatomy and Morphology of the University of London; has served as secretary of the Anatomical Society of Great Britain and Ireland, as professor in anatomy in University College, Sheffield, and as editor of the *Quarterly Medical Journal.* He is the author of monographs on "The Pancreas and Adjoining Viscera," "Topographical Anatomy of the Abdominal Viscera and Especially the Gastro-Intestinal Canal in Man," and many other brochures on the subject of anatomy, and is joint author with Major Jennings of the book entitled, "With the Abyssinians in Somaliland," which appeared in 1905. Since 1910 Sir Christopher Addison has been a member of parliament from the Hoxton District of Shoreditch, and more recently parliamentary secretary of the board of education, and undersecretary of state, ministry of munitions.

PARIS LETTER

Paris, Nov. 8, 1917.

The War

COMPASS LOCALIZER FOR THE EXACT DETERMINATION OF THE DEPTH OF PROJECTILES

At a recent session of the Académie de médecine, M. Nemirovsky exhibited a new apparatus for localizing a projectile in a few minutes without making any measurements, calculations or diagrams, thus eliminating the most frequent sources of error. A rod index indicates the exact position of the projectile. The compass is used with the roentgen rays and, by means of an ingenious attachment, can be adapted to any screen. It is based on the method of the double image; the first is supplied by the standard ray, the second proceeding from the tube moved along a trifle. The localization can be made a few minutes before the operation because it is not necessary (as in the case of other compasses) to make the radioscopic test to disclose the approximate position of the projectile. It is easy and simple to adjust, and the results obtained are exact. During the operation, the compass guides the operator to the foreign body, no matter what route of approach is chosen. It permits, besides, the localization of many projectiles and their extraction with the same apparatus at the same time. The apparatus being firm and solid cannot get out of order, neither during the sterilization, nor during the operation, and the rods are interchangeable, numbered and graduated.

SURGICAL TREATMENT OF STUBBORN REFLEX CONTRACTURES OF THE EXTREMITIES

At one of the recent meetings of the Société de chirurgie de Paris, Dr. Le Fort of Lille read a paper on this subject which can be summarized as follows: Reflex contractures, in the great majority of cases, are amenable to medical treatment. They have a tendency to cure themselves, as a rule, and hysterical reflex contractures occur often. Psychotherapy, isolation and physiotherapy are the basis of all treatment. But certain severe and stubborn forms may lead to fibrous contractures and definite disability, and in these exceptional cases, surgery can and should intervene. Tenotomy is indicated, but it is often followed by a recurrence. In the intractable cases, arthrodesis can be done as a last resource. The peripheral sympathectomy of Leriche gives very good results when vasomotor disturbances predominate; it acts only indirectly on the muscular contractures. Excision of the cicatrix, the origin of the reflex trouble, can be attempted when the cicatrix is imperfect or painful and when complete excision is possible. Resection of the sensory nerve trunks is an excellent procedure, when anesthesia of these trunks by means of cocain relieves the contracture. When this is inapplicable, when all other methods have failed, when the condition is very grave and the patient accepts the risk of a serious operation, an experienced surgeon may, perhaps, in a few cases, and only when all these conditions are fulfilled, attempt the resection of one or two posterior roots, corresponding to the zone of the cicatrix, if such resection can, as for the lumbar and sacral nerves, be made outside of the investing dural sheath.

THE HEMATOLOGIC INDICATIONS FOR IMMEDIATE TRANSFUSION SOON AFTER A WAR WOUND

Drs. Depage and Govaerts (of the Belgian army), at one of the recent meetings of the Société de chirurgie de Paris, showed that one can make a diagnosis of a possibly fatal hemorrhage immediately after the patient has been wounded. Experience has shown that if the number of red blood cells in the venous blood is notably diminished, if less than 4,000,000 in the first six hours, the prognosis is nearly always fatal. In such cases, the injection of artificial serum is useless; consequently, blood transfusion is an absolute indication. These principles apply solely to cases of wounds of the extremities. With wounds of the viscera, the red cell count is influenced by many factors, and the interpretation of a blood analysis is always difficult. The above figures apply only to healthy adults, which soldiers usually are. Under these conditions, one can, by taking cognizance of the time elapsed since the occurrence of the injury, consider as evidence of an extremely grave hemorrhage, hence a positive indication for immediate transfusion, the following counts: Less than 4,500,000 in the first three hours, less than 4,000,000 in the first eight hours, and less than 3,500,000 in the first twelve hours. Depage and Govaerts have practiced systematic blood transfusion in cases of wounds of the extremities where blood examination, based on these principles, has demonstrated the existence of grave hemorrhage. Among fourteen patients, three died of a subacute infection (gas gangrene, *Bacillus perfringens* septicemia). It is evident, then, that when an infection is in the course of development during the first few hours after the wounding, transfusion is unable to save the life of the patient. Among the remaining eleven cases in which there was no subacute infection, eight were completely successful. Of the three failures, one was due to hemoglobinuria, and in the other two it can only be surmised that the transfusion of one-half liter of blood was insufficient. In certain cases, therefore, it will be necessary to inject, not one-half liter, but a whole liter of blood. For that purpose one may make use of two donors, having first made sure that their blood is not reciprocally agglutinable.

The immediate effect of the transfusion is most remarkable, very different from that which follows the injection of artificial serum. In some cases the result is truly astonishing. The patient, previously unconscious, seems to revive, the mucous membranes resume their color, and there is every evidence of a great change for the better in the condition of the patient. The blood pressure rises immediately, and this improvement is permanent. If the blood pressure drops within a few hours, it is a sign of a subacute infection for which, unfortunately, we have no remedy at the present time. A blood count made a few days later shows that the injected red blood corpuscles are not destroyed, that is, if one has taken precautions against agglutination. The anemia present is like that following moderate hemorrhage. The red blood cell count is never lower than 2,500,000. It seems, then, that great progress can be realized, thanks to this early detection of hemorrhages, sufficiently serious to menace life. If the blood count shows that the hemorrhage of itself will be fatal, then transfusion is an absolute indication. Transfusion can be done under the most simple technic without any danger to the donor, and proves a life-saving measure for patients irremediably doomed were it not for this heroic treatment.

Marriages

Lieut. Charles Gerald LaRocco, M. R. C., U. S. Army, Cleveland, to Miss Marie L. Kelley, both of Cleveland, in St. Louis, November 18.

Lieut. William Christian Jensen, M. R. C., U. S. Army, to Miss Myrtle R. Hatch, both of Worcester, Mass., at Oak Park, Ill., November 29.

Alfred James Leary, M.D., Newton, Mass., to Miss Helen M. Howard of Portsmouth, N. H., November 21.

Charles LeRoy Zimmerman, M.D., White Eagle, Okla., to Miss Edna Robbins of Oklahoma, recently.

Charles L. Seitz, M.D., Evansville, Ind., to Miss Arnia Lloyd of Shelbyville, Ind., November 19.

Francis Peter Boyd, M.D., to Miss Margaret H. Shea, both of Springfield, Mass., November 22.

Herbert Rogers Etheridge, M.D., to Miss Courtenay Arps, both of Norfolk, Va., November 21.

Deaths

Thomas Freeman Moses, M.D., Waltham, Mass.; Jefferson Medical College, 1861; aged 81; acting assistant surgeon, U. S. Army, during the Civil War; a Fellow of the American Academy of Medicine; from 1870 to 1894, a professor in the Urbana (Ohio) University, and for eighteen years president of the institution; died at his home, November 21.

Levi Pickett Esslinger, M.D., New Market, Ala.; University of Alabama, Mobile, 1903; aged 42; formerly a Fellow of the American Medical Association; a member of the Medical Association of the State of Alabama; a specialist on diseases of the eye, ear, nose and throat; died in a hospital in Nashville, Tenn., August 6, from gastric ulcer.

James William Koontz, M.D., Greenville, Ky.; Kentucky School of Medicine, Louisville, 1894; aged 47; formerly a Fellow of the American Medical Association; local surgeon for the Illinois Central System; a director of the Inter-Southern Life Insurance Company, Louisville; died in a hospital in Charleston, W. Va., November 20.

Asst. Surg. Dudley W. Queen, U. S. N. R., Temple, Texas; University of Louisville, Ky., 1912; aged 31; a member of the State Medical Association of Texas; for six months an officer of the Medical Reserve Corps of the Navy, and on duty on the U. S. Destroyer *Cassin,* which was torpedoed a few days ago; died in Ireland, November 20.

John R. Dink, M.D., Brandenburg, Ky.; Louisville (Ky.) Medical College, 1894; aged 49; a Fellow of the American Medical Association; for many years health officer of Neade County; selective draft examiner, for his district; died in St. Joseph's Infirmary, Louisville, November 17, two weeks after an operation for abscess of the brain.

Basil M. Woolley, M.D., Atlanta, Ga.; Atlanta (Ga.) Medical College, 1882; aged 82; a Confederate veteran; who was struck by an automobile, October 26; died from his injuries in the Davis-Fischer Sanitarium, Atlanta, October 28.

George William Fraker, M.D., Excelsior Springs, Mo.; University Medical College of Kansas City, 1891; Eclectic Medical University, Kansas City, 1906; aged 59; died in Wesley Hospital, Kansas City, Mo., November 8.

Died in the Service
MAJOR RICHARD WEIL, M. R. C., U. S. ARMY, 1876-1917
(*See The Journal, last week, p. 1899*)

Eugene B. Nash, M.D., Cortland, N. Y.; Homeopathic Hospital College, Cleveland, 1874; aged 79; formerly professor of materia medica in the New York Homeopathic Medical College; died at his home, about November 6.

Simeon Cole Bradley, M.D., Nyack, N. Y.; College of Physicians and Surgeons in the City of New York, 1880; aged 62; a retired practitioner; also a graduate in pharmacy; died at his home, November 13, from heart disease.

Daniel M. Bloom, M.D., New Waterford, Ohio; Eclectic Medical Institute, Cincinnati, 1875; aged 64; formerly a member of the Ohio State Medical Association; died in his office, October 26, from heart disease.

James Nelson Harris, M.D., Chicago; Indiana Medical College, Indianapolis, 1907; a Fellow of the American Medical Association; a colored practitioner; was shot and killed in his office by his fiancée, November 15.

Charles Watson Snyder, M.D., Clyde, Mich.; College of Physicians and Surgeons, Chicago, 1903; aged 37; a Fellow of the American Medical Association; died at his home, November 15, from nephritis.

William O. Benson, M.D., Milford, Ind.; Hering Medical College, Chicago, 1900; aged 48; formerly a member of the Indiana State Medical Association; died at his home, November 11, from pneumonia.

Abraham Philip Fetherolf, M.D., Allentown, Pa.; Bellevue Hospital Medical College, 1865; aged 74; surgeon to the Lehigh Hospital and Sanitarium, Allentown; died at his home, November 19.

D. Howard Johnston, M.D., Philadelphia; Hahnemann Medical College, Philadelphia, 1883; a member of the Medical Society of the State of Pennsylvania; died at his home, November 9.

John H. Sloan, M.D., Sante Fe, N. M.; Cincinnati College of Medicine and Surgery, 1881; aged 65; formerly a member of the New Mexico Medical Society; died at his home, November 15.

William S. Deutsch, M.D., St. Louis; Missouri Medical College, St. Louis, 1892; aged 46; a Fellow of the American Medical Association; died at his home, October 9, from diabetes.

George W. White, M.D., Canon City, Colo.; Medical College of Ohio, Cincinnati, 1868; aged 72; died at his ranch on Cottonwood Creek, about 30 miles from Canon City, November 10.

Honoré Joseph Coté, M.D., Boston; Tufts College Medical School, Boston, 1899; aged 56; a Fellow of the American Medical Association; died, November 7, from cerebral hemorrhage.

Hiram M. Tabor, M.D., Olive Hill, Ky.; Kentucky School of Medicine, Louisville, 1899; aged 50; formerly a Fellow of the American Medical Association; died at his home, November 8.

William Huber Hoffa, M.D., Benton, Pa.; Medico-Chirurgical College of Philadelphia, 1904; aged 36; coroner and sheriff of Columbia County; died at his home, November 11.

J. George Stuckey, M.D., New Philadelphia, Ohio; University of Wooster, Cleveland, 1889; aged 55; a member of the Ohio State Medical Association; died at his home, October 15.

George Lindenmeyr, M.D., New York City; College of Physicians and Surgeons in the City of New York, 1888; aged 51; died at his home, November 15, from heart disease.

M. L. Withers, M.D., Wallace, Va.; College of Physicians and Surgeons, Baltimore, 1878; aged 69; died in a hospital near Richmond, Va., November 10.

Edwin G. Rummel, M.D., Butler, Ohio; Western Reserve University, Cleveland, 1898; aged 45; died at his home, November 14, from pneumonia.

Albert Monroe Wortman, M.D., Baltimore; Washington University, St. Louis, 1873; aged 65; died at his home, November 12, from diabetes.

Leonidas B. Martin, M.D., Peoria, Ill.; Rush Medical College, 1868; aged 72; died at his home, November 2.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

NOSTRUMS IN RETROSPECT

A Review of Worthless or Unscientific Proprietary Mixtures Previously Criticized

[Foreword.—The article that follows is the second[1] of a series written primarily for the purpose of reviewing the findings of the Council on Pharmacy and Chemistry on certain unscientific or worthless proprietary mixtures. Although the preparations which will be taken up in this series have been extensively dealt with in previous reports, the fact that they are still widely advertised and sold indicates the need of further publicity. The series is written by a man who is thoroughly conversant with the work of the Council on Pharmacy and Chemistry and can speak authoritatively on questions dealing with the actions of drugs in the treatment of disease.]

[Article II]

ANASARCIN AND ANEDEMIN

By S. Q. Lapius, M.D.

"Anasarcin" and "Anedemin" are the twin nostrums of cardiac pseudotherapy. They are dubbed "twin nostrums" not so much because of any similarity in their formulas, that being a minor consideration in the average nostrum, but because of the close similarity in their methods of exploitation, the therapeutic claims made for them, and the time and place of their birth.

It may be remembered that they both claim Winchester, Tenn., as their birth-place, and they appeared on the market at about the same time; furthermore, a comparison of the claims formerly made for both of them indicated that one mind conceived the main idea that lies back of their exploitation. While Anasarcin is especially dealt with in this article, much of the discussion applies with equal force to Anedemin.

A LUSH FIELD FOR NOSTRUMS

Cardiac disease, with its resultant renal involvement, is frequently encountered; and running, as it does, a chronic course, it offers an almost ideal field of exploitation for the typical nostrum vendor. By a typical nostrum vendor we mean one whose knowledge of his product is far below that of his appreciation of a certain element of human character. On this element rests the whole secret of the nostrum vendor's success. It is variously termed credulity, gullibility and child-like simplicity, but it is that which often causes even the most conscientious clinician to turn aside from the use of the best known and most dependable drugs at his command, in the face of disappointment and failure, and employ some vaunted mixture which in his saner moments he scorns to use.

Anedemin is said to consist of a "Scientific Combination of three of the more recently investigated members of the Digitalis Series, with Sambucus." That is, of apocynum, strophanthus and squill with elder. It is difficult to know just what idea it is intended to convey by the statement that it is a "scientific combination" of these drugs, for it is unscientific to mix three drugs of this group for use in fixed proportion in a wide range of conditions, if indeed, there is ever any indication for their use.

The great disadvantages of strophanthus and apocynum pertain to the extreme uncertainty of their absorption from the gastro-intestinal tract. Strophanthus is occasionally absorbed promptly, sometimes so slowly that the therapeutic effects are not induced until an amount equal to several times that which would prove fatal if all of it were absorbed into the circulation has been administered, and unfortunately, one cannot control the absorption which may continue until a fatal effect is induced. This is true to an even greater degree of apocynum, and it was due to the recognition of this fact that apocynum was not admitted to the U. S. P. IX, the Committee on dosage having agreed that no safe and effective dose could be given.

THE COUNCIL'S PREVIOUS FINDINGS

In 1907 the Council on Pharmacy and Chemistry examined the literature used in the exploitation of Anasarcin and Anedemin and published its report. Anasarcin tablets, it was pointed out, were said to contain the active principles of *Oxydendron arboreum* (sour wood), *Sambucus canadensis* (elder) and *Urginea scilla* (squill), and the following claims were made for the nostrum:

> "Does what dropsy medicaments have hitherto failed to accomplish."
>
> "Superior to digitalis, strophanthus, scoparius, squills, acetate of potash and the hydragogue cathartics all put together."
>
> "The only known relief and permanent cure of dropsies."
>
> "Unrivaled heart tonic."
>
> "The most powerful agent known."
>
> "Safe in administration."
>
> "Non-toxic as ordinarily administered."
>
> "Will nauseate some persons," but "the reaction from the temporary depression is prompt."
>
> "In Bright's disease, both the interstitial and parenchymatous forms of nephritis, acute or chronic, no remedy . . . to equal it in efficacy."
>
> "Without increasing the debility of the patient or interfering with nutrition by producing loss of appetite . . ."
>
> "This treatment is to be continued without cessation until all symptoms of dropsy have disappeared."

A comparison of the earlier claims with those now being made (see advertisement reproduced from the *New York Medical Journal*) illustrates one of the results of the work of the Council. Today the nostrum exploiter avoids the cruder forms of obvious misstatement, but continues to make, by inference, claims that are equally misleading. It will be observed in this case that a more cautious pen worded the later advertisement, but there is still evident the intent to convince the reader that Anasarcin is superior to the official drugs in the treatment of cardiovascular diseases. The facts are that Anasarcin is at best a dangerous remedy in the hands of the average clinician in the treatment of such conditions, and its use is at all times to be condemned.

No competent investigator has ever investigated the pharmacology of sour wood (*Oxydendron arboreum*), and it appears to have no therapeutic value other than that due to a slight acidulousness. Elder (*Sambucus canadensis*) contains a trace of a volatile oil as its most important constituent, according to the British Pharmaceutical Codex of 1911 (p. 908), but it is difficult to explain why a trace of volatile oil should be considered important. Elder may be dismissed without further consideration in connection with Anasarcin tablets.

THE PHARMACOLOGY OF SQUILL

This leaves only squill among the constituents of Anasarcin for consideration. Sollmann (Manual of Pharmacology, 1917, p. 409) in discussing the advantages claimed for squill over other drugs of the digitalis group, says: "Dixon, 1906, points out that any superiority is outweighed by its disadvantages: uncertain absorption; strong gastro-intestinal irritation." Squill was formerly used as expectorant and diuretic, the activity having been attributed to two amorphous glucosids, scillipicrin and scillitoxin, but Ewins, 1911, found these to be impure mixtures. A later investigator claimed to have isolated two glucosidal agents from squill, but similar claims have often been made only to be disproved later, and we know of no confirmation of the claims regarding the isolation of any pure principles from squill having any true typical digitalis action.

The statement quoted from Sollmann is accepted by practically all pharmacologists, and we may say with certainty that squill is decidedly inferior to digitalis in the treatment of cardiovascular, and cardiorenal diseases, and certainly no active principles of squill were known to the scientific world at a time that the remarkable claims were first made for Anasarcin by an obscure pharmacist of Winchester, Tenn. Indeed, if Anasarcin were all that it was claimed to be, its discovery would have made Winchester as famous as a certain Wisconsin city was said to have been made by a popular beverage.

---

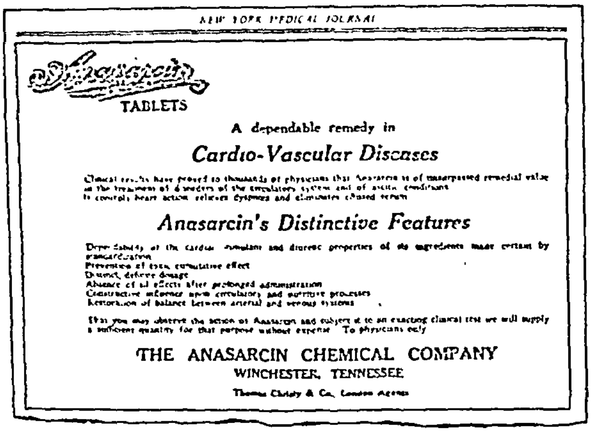
[1] The first article dealt with "Bell-Ans" ("Papayans-Bell") and appeared in The Journal, Nov. 24, 1917, p. 1815.

It has been abundantly demonstrated, and it is now almost universally accepted among well informed pharmacologists and clinicians, that all digitalis principles exert the same kind of action on the heart after they enter the circulation in effective doses, though they differ to an extraordinary degree in the intensity of their action and in their undesired side-actions such as nausea and vomiting. When the use of Anasarcin (squill) is followed by immediate improvement after digitalis has failed it merely shows that the dosage of digitalis was insufficient or that it was discontinued and the squill mixture was substituted before the full therapeutic effects of the digitalis developed.

WHEN THE DIGITALIS GROUP IS CONTRAINDICATED

If the administration of a sufficient dose of digitalis is not followed by improvement in the circulation it shows that the heart is incapable of responding to such treatment and the further use of any of the drugs of this group is distinctly contraindicated. This is confirmed by the experience of nearly every competent observer of digitalis therapy, and numerous fatalities have resulted from the failure to appreciate this fact and further administer some other member of the group, such as strophanthus or squill.

It is now well known that the cardiac effects of toxic doses of squill, and other members of the group, resemble closely those of cardiac disease, and it is often impossible to determine whether the behavior of the heart in a given case is attributable to insufficient dosage, to excessive dosage, or to the progress of the cardiac disease itself. If this occurs when one uses the best known members of the group it is certain that it occurs even more frequently when others that are less understood, are employed. In the light of this knowledge of the dangers attending the incautious use of any member of the digitalis group, and more especially the use of impure principles, such as are commonly obtained from squill, it is impossible to condemn sufficiently the recommendation that the use of Anasarcin should be continued without cessation until all symptoms of dropsy have disappeared.



NEW YORK MEDICAL JOURNAL

TABLETS

A dependable remedy in

Cardio-Vascular Diseases

Clinical results have proved to thousands of physicians that Anasarcin is of unsurpassed remedial value in the treatment of disorders of the circulatory system and of ascitic conditions
It controls heart action, relieves dyspnea and eliminates effused serum

Anasarcin's Distinctive Features

Dependability of the cardiac stimulant and diuretic properties of its ingredients made certain by [illegible]
Prevention of toxic cumulative effect
Distinct, definite dosage
Absence of ill effects after prolonged administration
Constructive influence upon circulatory and nutritive processes
Restoration of balance between arterial and venous systems

That you may observe the action of Anasarcin and subject it to an exacting clinical test we will supply a sufficient quantity for that purpose without expense. To physicians only

THE ANASARCIN CHEMICAL COMPANY
WINCHESTER, TENNESSEE
Thomas Christy & Co., London Agents

Digitalis bodies are not suited for the treatment of all cardiac disturbances, and it is, of course, self-evident that a time must come in the treatment of chronic cardiac disease when the heart is incapable of responding to any form of treatment with improvement. But, unfortunately, it never loses its response to toxic doses, and to push the administration of any drug or mixture containing any drug of the entire digitalis group—and especially those, like squill, in which the side actions are most prominent—beyond the point of tolerance is to court certain disaster.

THE TREATMENT OF CARDIAC DROPSY

While it is quite certain that many lives have been sacrificed to the failure to understand this phase of cardiac therapy, it is equally certain that many lives have been sacrificed because of insufficient dosage, and one can steer a safe course between these dangers only by using the best known preparation available, and in the present state of our knowledge it is indisputable that digitalis and the tincture of digitalis are best suited for the treatment of cardiac disease except in those few cases in which intramuscular or intravenous administration must be employed temporarily for immediate effect.

The secret of prescribing successfully for the relief of dropsy in cardiac disease consists in understanding the effects of digitalis on the heart, in administering it until these effects indicate that the desired object has been obtained, and stopping, or interrupting, the administration at that point until the effects begin to wear off. *Cumulation*, so called, is a positive advantage in such cases. It merely means that the desired therapeutic effects once induced persist for a time, and that further medication is unnecessary during such persistence of action. Eggleston has recently shown (*Arch. Int. Med.*, July, 1915, p. 1; abstr., The Journal, July 31, 1915, p. 459) that the full therapeutic effects of digitalis can be induced in suitable cases within a few hours even with oral administration.

We are not aware of a single publication in which a careful detailed clinical study of Anasarcin has been reported. The claims made for Anasarcin, past and present, indicate either a deliberate purpose to mislead or crass ignorance of the rudiments of pharmacology and therapeutics. The exploiters of the nostrum claim that thousands of physicians have found Anasarcin tablets of unsurpassed remedial value in the treatment of disorders of the circulatory system and of ascitic conditions.[2] It must be admitted that too many physicians have prescribed Anasarcin, otherwise the manufacturers would not have continued to spend thousands of dollars in advertising it in medical journals during a period of more than ten years.

Doctor, this article is meant to be a candid discussion with you, whether you use Anasarcin or not, because every clinician is vitally interested in the customs that obtain in the practice of medicine, and we wish to put a hypothetical question to you. Answer it, at least to yourself, in exactly the spirit in which it is put. Suppose that you prescribe Anasarcin for a patient who is critically ill with cardiac disease. He dies. Are you willing to tell the relatives frankly just what you used and the nature of the evidence on which you based your choice of this nostrum? Let the supposition be carried further and say that the case was hopeless, and agree that digitalis and all other drugs would have been equally ineffective. Granting all this, would your explanation satisfy? Would you in all candor dare to offer such an explanation? Try it as a hypothetical case before you are forced to apply it.

---

[2] Former estimates of the number of physicians who prescribed Anasarcin appear to have been too high, possibly based on the ratio obtaining in Winchester, Tenn. Inquiry at five fairly busy drug stores in a large eastern city showed that in no instance was the pharmacist even acquainted with the name. One pretended to be, and manifested pity for the enquirer's ignorance in supposing that it could be imported during the war! He was obviously merely less honest than the others, who frankly admitted they had never heard of it.

Alternating Method of Exterminating Mosquitoes.—The two Sergents, who have contributed much to tropical medicine, recently presented to the Académie des Sciences at Paris a report on what they call the alternating breeding-place method. They state that as the larvae of mosquitoes require about three weeks in water before the larvae develop into perfect winged insects, by diverting the water away, leaving the area without standing water, the stranded larvae will die off. The larvae deposited in the diverted water can likewise be killed off by diverting the water back again into its primary place. By thus alternating, week by week, the breeding places, the mosquitoes get no chance to develop, while the expense of this alternate draining may be minimal in comparison with the expense of oiling large areas of water, etc.

Correspondence

THE CARREL-DAKIN TREATMENT

[Dr. Welch and Dr. Bevan request the publication of the following letter, which is a reply to the one appearing in The Journal, November 17, page 1727. A reply by Dr. A. T. McCormack is postponed till next week through lack of space.—Ed.]

Dear Bevan:—Thank you for your letter about the Carrel treatment of wounds, in which I am much interested.

I had the opportunity a year ago at Compiègne to observe the method and results of this treatment, and was most favorably impressed, as every one who has been there is. There can be no question that Carrel deserves the credit—and a very considerable credit this is—of recalling the attention of surgeons to the possibility of the sterilization of infected wounds by chemical means. The idea is, of course, not new, but is the original listerian one. That the Carrel-Dakin procedure actually accomplishes such sterilization sufficiently for surgical purposes is quite conclusively demonstrated, and whatever changes be made in his technic as the result of further experiences, he will deserve the credit of reapplying a great surgical principle of wound treatment, which had been practically abandoned, just as Lister will always have the credit of introducing the principles of antisepsis, though his technic be abandoned.

I was particularly interested when at Compiègne in following the Carrel method of bacteriologic control of the flora in the wound. I studied the smears made day by day from the wounds. These smears at first gave information concerning the numbers, and to a considerable extent also, the kinds of bacteria present. It was fascinating to watch the reduction, often astonishingly rapid, at other times slower, of these bacteria under the irrigation by the Dakin fluid. It was a quite novel thing to find the bacteriologist occupying this relation to the surgeon and telling him when the wound could be safely closed. The cicatrization after closure under this bacterial control was amazingly rapid.

The only other place where the Carrel treatment was consistently and correctly applied was by Depage at La Panne, which I did not visit, but I was told the results were admirable. Hutchinson returned from La Panne when I was in Paris, and was about to introduce the Carrel method at the American Ambulance at Neuilly.

Undoubtedly the technic of the Carrel treatment is elaborate and requires an intelligence and skill on the part of the surgeon which cannot be counted on for the average surgeon. The preparation of the Dakin solution also requires chemical skill. There are certainly difficulties in carrying out the Carrel treatment under the condition of actual warfare, and opinions may differ as to the extent of its applicability under these conditions; but this does not alter the fact that Carrel has made a very important contribution to the subject of wound treatment, and that surgeons should acquaint themselves with the principles and technic, and try to overcome the difficulties of applying the treatment as widely as possible.

I am not at all in sympathy with Sherman's efforts to have the treatment made obligatory or to have the Surgeon-General order this or any other method of treatment as the only correct procedure. There is not the slightest danger of any such thing happening. I am, of course, in sympathy with every effort looking to earlier treatment of wounds received at the front than was customary in the earlier stages of the war, and probably many wounds could be promptly closed which now are allowed to become badly infected, and thus the field for the Carrel treatment would be narrowed.

I see no conflict with the teachings of surgical pathology in Carrel's work. Of course, the cells and fluids must be relied on to take care of invading bacteria, and Almroth Wright felt, as you seem to feel, that what Carrel was aiming to do—destroy bacteria on the surface of wounds—was unimportant compared with reliance on the cellular defenses. Experience with the Carrel method, however, proves conclusively that the destruction of these surface bacteria without injury to the body tissues is of primary importance. So many who discuss this question seem to lose sight of the fact that a great principle is really involved, viz., that of the sterilization of wounds by chemical methods without damage to cells, and the influence of such sterilization on the repair of wounds. Carrel's work is fundamental on this point.

I understand that the Germans have taken over the Carrel method of wound treatment and are applying it most successfully. It would be melancholy to repeat the experience with Lister, who, discredited in his own country by all the surgeons, was taken up in Germany and his principles were there established so that his country had to accept him. I wish that you could have been at Compiègne and could have seen the actual results. These are quite unequaled, as Almroth Wright himself told me, and as so many have testified. We have enough in the way of control by other methods, I think, to justify this statement.

I visited Blake, whose great work is not in the line of wound treatment, but in the treatment of fractures. Halsted has been using the Carrel method in suitable cases for a long time, for over a year, and is most enthusiastic over it, but seems to feel that not many surgeons will master it.

Of course, much has appeared in the newspapers which is exaggerated and deplorable, and this is calculated to create a prejudice against Carrel; but I do not think that he is responsible for this.

William H. Welch, M.D., Baltimore.

"THE TREATMENT OF INFECTED WOUNDS"

To the Editor:—In The Journal, Nov. 10, 1917, p. 1645, appeared a review of the book by Carrel and Dehelly on "The Treatment of Infected Wounds." The larger part of the "review" is devoted to adverse criticism of statements ascribed to myself. While I am in no way responsible and had no previous knowledge of the matter in the book in question, the reviewer indulges in so many statements that are misleading or incorrect, that I deem it desirable to draw attention to the matter. In doing so, I wish to confine myself as far as possible to definite questions of fact, believing that the obvious animus of the reviewer will be adequately recognized by those who have interest in such matters.

The reviewer apparently regards it as fair play to record a list of antiseptics with which I have worked and to attach to them fantastic names which do not appear in the book nor have ever been employed by me, but which he apparently derives from advertising matter with which I have no connection in any way. He then proceeds to state, "Yet in all these 'discoveries' the potent agent has always been active chlorin (positively charged chlorin [Cl^+]), the same substance with which the medical profession has had well tried experience when employing calcium hypochlorite (bleaching powder) and the much abused solution of chlorinated soda (Labarraque's solution)." This statement is disingenuous and misleading. That "active chlorin" was contained in the substances is not surprising, since that was the object avowedly sought; but that positively charged chlorin ions, Cl^+, are the active agent in each case is a gratuitous assumption without a shred of evidence. As a matter of fact, hypochlorite solutions appear to ionize mainly to ClO^- ions. That the chloramins dissociate differently is evident from the fact that while the hypochlorites bleach indigo solutions, the former do not. Moreover, their reactions with many other substances, including proteins, are often quantitatively and qualitatively different. The suggestion that Cl^+ ions are the active agents in all the chlorin antiseptics is as without basis as the assumption of the equivalence of white arsenic and salvarsan. If any one imagines that the various chlorin antiseptics are chemically equivalent, he will be speedily disillusioned if he perform the simple experiment of putting pieces of any animal tissue in the solutions and observing the result.

The reviewer states that "the authors uphold Dakin's claim that this solution . . . is isotonic with the blood." As a matter of fact, I have never made such a claim, and have always known the solution to be hypertonic.

The reviewer states that "Dakin's solution is *not* neutral, but is alkaline, and should be alkaline when prepared in the manner described." My actual statement is as follows: "The solution is acid to phenolphthalein suspended in water, but *still alkaline to litmus.*"

Commenting on the use of phenolphthalein in aqueous suspension instead of in solution, the reviewer states, "It is, indeed, surprising that phenolphthalein should thus be used when every student in elementary analysis is taught that it is not reliable in such conditions." This statement is absolutely incorrect so far as the testing of hypochlorite solutions is concerned. Apparently the reviewer is unaware of the fact that hypochlorites react with the ordinary solutions of phenolphthalein to give chlorinated products and alkaline caustic soda, thus giving false indications of alkalinity. The use of phenolphthalein suspensions in water for testing the reaction of hypochlorite solutions has occasioned no difficulty in the hands of even inexperienced workers, and undoubtedly serves to avert the use of highly irritating solutions.

The reviewer, in contesting the approximate neutrality of the solutions, makes the following naive comment: "If to some of Dakin's solution alkali be added, and the solution then tested by phenolphthalein, it will still give the 'neutral' reaction." It has apparently escaped the notice of the reviewer that this condition was deliberately sought. The use of a balanced solution of hypochlorite containing "buffer salts" (bicarbonates or borates) was purposely chosen because such solutions "are able to retain their essential neutrality even after the addition of limited quantities of acid or alkali." It will, of course, be recalled that exact neutrality is an ideal and unobtainable condition, and that in everyday usage a solution is said to react acid, alkaline or neutral simply with regard to some arbitrarily chosen indicator.

Finally, may I add a word of personal explanation. No one deplores more than I do the ludicrous exaggerations of the daily press as to the utility of the solution which has become associated with my name. As a matter of fact, in none of my own writings in scientific journals have I coupled my own name with the solution, but have simply described the preparation as an approximately neutral sodium hypochlorite. In December, 1915, I wrote, "It would seem as if the time had come for a statement to the effect that what we have all been striving for is to find the best means of preparing, preserving and applying the powerful antiseptics, hypochlorites and hypochlorous acid, the main properties of which substances were discovered by distinguished French chemists many generations ago." So far as the hypochlorites are concerned, this is as true now as then.

H. D. Dakin, New York.

Comment of the Reviewer.—I regret that Dr. Dakin has made it necessary to deny any personal animus in my review of "The Treatment of Infected Wounds," by Carrel and Dehelly. What criticisms were made were made solely for scientific reasons.

Dr. Dakin places an unusual interpretation on my statement, "Yet in all these 'discoveries,' the potent agent has always been active chlorin (positively charged chlorin [Cl^+]). . . ." Contending that the statement is disingenuous and misleading, Dr. Dakin says: "That 'active chlorin' . . . was the object avowedly sought, but that positively charged chlorin ions, Cl^+, are the active agent in each case is a gratuitous assumption without a shred of evidence." In other words, Dr. Dakin differentiates between active chlorin and positively charged chlorin (*atoms, not ions.* The term *ion* was not used in the review). This is quite contrary to present day concepts. According to modern chemistry, oxidation may "be considered to involve ultimately the assumption of positive, or the loss of negative electrical charges by ions or atoms" and defined "as consisting fundamentally in the *loss of electrons by atoms or ions*" (Stieglitz: Qualitative Chemical Analysis, The Century Company, 1911, Part I, page 252). Thus hypochlorous acid [($Cl^+\overline{OH}$), which, besides ionizing into H^+ and $\overline{ClO}$ dissociates into Cl^+ and $\overline{OH}$], hypobromous acid (Br^+OH), hypoiodous acid (I^+OH) *and their derivatives* have as a common characteristic an atom with an unstable positive charge and a tendency to convert this atom into the common, stable, negative variety (Stieglitz and Senior, *Jour. Am. Chem. Soc.*, 1916, **38**, 2727), and therefore are *active* oxidizing agents. There is also convincing evidence to show that the chloramins (described by Dr. Dakin) contain positively charged chlorin as in the case of hypochlorite: (1) The formulas described by Dakin and methods of preparation (the replacing of a hydrogen atom of an amido group by chlorin) strongly suggest that the chlorin is positively charged. (2) On hydrolysis, they yield hypochlorous acid. (3) They are *active* oxidizing agents. I believe that if Dr. Dakin will consider these points, along with the classic researches of W. A. Noyes, Julius Stieglitz, Harry Shipley Fry, Lauder W. Jones and others, he will be convinced that I did not err.

In referring to the "isotonicity" of the Dakin-Daufresne solution ("Neutral" Solution of Chlorinated Soda, N. N. R.), I inadvertently had in mind an article by Daufresne, instead of Dakin. In this article (Daufresne, Maurice: L'hypochlorite de soude chirurgical. Différence entre la solution de Dakin et celle de Labarraque, *Presse méd.*, Oct. 23, 1916, p. 475), Daufresne states that "elle est sensiblement isotonique au sérum sanguin" ("it is perceptibly isotonic to blood serum"). I am sorry that this statement was attributed to Dr. Dakin; it happened, undoubtedly, because of the close association that has existed between the names of Daufresne and Dakin in their mutual work. However, so far as I am aware, this is the first time Dr. Dakin has publicly admitted the hypertonicity of the solution.

When I commented on the use of phenolphthalein, I did not have reference to its use as a solid instead of in solution. My contention was and is that phenolphthalein is "not reliable in such conditions," i. e., in the presence of *bicarbonates* and *hypochlorites.* The assertions in the review concerning the fallacy of the phenolphthalein indicator were made advisedly as a result of both theoretical considerations and a number of experiments. Dr. Dakin himself states that "hypochlorites react with ordinary solutions of phenolphthalein to give chlorinated products and alkaline caustic soda, thus giving false indications of alkalinity." This statement is in accord with my contentions, as, of course, phenolphthalein is only an indicator when in solution, whether it be added as such or "dusted" on as a powder. Furthermore, when we speak of neutrality, it should be understood that the neutrality is closely comparable to that of water. Dakin's solution does not have such neutrality, but is distinctly alkaline, part proof of which is the evidence offered by Dr. Dakin that it is *"alkaline to litmus."* Even under normal conditions, litmus is a more reliable indicator of alkalinity than phenolphthalein. Dr. Dakin's definition of neutrality would seem to be rather hazy, especially when, in the condition employed, the indicator is unreliable. The sooner writers will recognize that a solution is really neutral when the concentration of the H and OH ions is the same as exists in water, the sooner will there be less confusion in medical chemistry.

Dr. Dakin states that in none of his writings in scientific journals has he coupled his name with the solution. It might not be amiss to quote from page 23 of the recent "Handbook of Antiseptics" by Dakin and Dunham: "Neutral Sodium Hypochlorite Solution ('Dakin's Solution')."

The Reviewer.

"THE HANDICAP OF PROPRIETORSHIP IN MEDICINE"

To the Editor:—The article in The Journal, November 24, page 1818, with this title does us a gross injustice, and in reply thereto we beg leave to submit the following:

For reasons which every publisher (yourself included) understands, it is not practicable for us to reproduce in full, in the columns of *Therapeutic Notes,* all the clinical papers to which we wish to direct the attention of our readers. But that the article of Dr. Mundell was not garbled to make capital for Parke, Davis & Co. is quite apparent on comparison of the omitted portions with a previous paper by the same author reprinted in the January (1917) issue of the *Notes,* and herewith submitted together with clippings from other issues of the *Notes* which prove that we have not hesitated to present to our readers the dangers incidental to the misuse of Pituitrin as well as the advantages of its proper use.

Therapeutic Notes, in quoting other journals, puts into its readers' hands the means of investigating the fairness of its quotations. It is a house organ—true enough; but the organ of a house which has always appealed to the honor as well as to the progressiveness of the medical profession. Its publishers could not afford to resort to deception in advertising their products through this or any other medium.

The profession is indebted to Parke, Davis & Co. for Pituitrin (among other medicaments), and it is to the profession that the manufacturers look for the ultimate verdict. The contraindications are quite as important as the indications, and, as the excerpts submitted show, we have taken account of these, not only in forming our own estimate, but in presenting the evidence to the readers of *Therapeutic Notes.*

We cite these facts that you may give us a square deal in an early issue of The Journal if so disposed.

Parke, Davis & Co., Detroit.

[Comment.—The Journal has no desire to discuss Parke, Davis and Company's motives in omitting certain parts of Dr. Mundell's paper. What The Journal did was to publish those parts of Dr. Mundell's paper on the "Present Status of Pituitary Extract in Labor" that Parke, Davis and Company left out of their circular. That it is not practicable, as Parke, Davis and Company points out, for the manufacturers of proprietary products to reproduce in full all clinical papers dealing with such products is obvious. It is not so obvious why such concerns in abstracting or quoting papers of this kind should delete those parts that are unfavorable to the products dealt with rather than those that are favorable. Curiously, however, whenever an author is quoted only in part those parts are almost invariably those favorable to the product.—Ed.]

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

NO DRAFT OF MEN OVER 31 YEARS OF AGE

To the Editor:—1. I should like to know whether medical men (over the present draft age of 31 years) are to be drafted now or whether there is any possibility that this will be the case after the first of the year.

2. If the new draft age limit (from 18 to 45) is passed by Congress, will they take men from "country practices" where there is only one physician? My reason for wishing to know this is that if there is to be this necessity I should rather enlist than wait until the last and be drafted.

S. E. L.

Answer.—1. Under the present law, neither physicians nor other men over 31 years of age come within the selective service.

2. It is impossible to predict what may occur under new laws which may be passed until after these laws are passed. There is nothing in the present selective service law or in the regulations which would permit a special drafting of the medical profession.

TOEING IN

To the Editor:—What should I do, if anything, for a 2 year old child who "toes in" to an unpleasant extent when walking, although when standing he keeps the feet straight? The legs are well developed and are straight. He has had no illness except measles, and is in sturdy health. Is it worth while to apply braces, or will this fault correct itself in time?

W. J. W.

Answer.—A slight degree of toeing in is entirely natural, and indicates a strong foot. It is much to be preferred to a "toeing out" gait. Sometimes, however, it is present in an exaggerated degree; in such cases the trouble can be easily remedied by the use of a straight lasted shoe with a lift of one-fourth or three-eighths inch put under the outside of the sole. Great care must be taken that the shoes are sufficiently long. The empty space inside the shoe should extend at least one-fourth inch beyond the ends of the toes. It will be found that the heel will wear off unevenly on one side, and this should be kept squared up and not allowed to run over.

Maine March Examination

Dr. Frank W. Searle, secretary of the Maine Board of Registration of Medicine, reports the written and practical examination held at Portland, March 13-14, 1917. The examination covered 9 subjects and included 90 questions. An average of 75 per cent. was required to pass. Five candidates were examined, all of whom passed. Three candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Loyola University		(1916)	79
Bowdoin Medical School		(1916)	78
Tufts College Medical School	(1909) 82;	(1915)	83
McGill University		(1916)	92

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Dartmouth Medical School		(1891)	New Hamp.
Cincinnati College of Medicine and Surgery		(1900)	Ohio
University of Vermont		(1912)	Vermont

Alabama July Examination

Dr. S. W. Welch, chairman of the Alabama State Board of Medical Examiners, reports the written examination held at Montgomery, July 9-13, 1917. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. *Forty-four* candidates were examined, of whom 32 passed and 12 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Birmingham Medical College		(1915)	76.3, 79.2
University of Alabama	(1917) 75.9, 77.3, 77.8, 79, 79.4, 79.5, 80, 81.3, 84.1, 84.2, 84.2, 85.4.		
Atlanta Medical College	(1916) 77.2; (1917) 78, 83.8, 84.8.	(1916)	75.4
Chicago College of Medicine and Surgery		(1916)	75.9
Loyola University		(1916)	84.5
University of Louisville		(1917)	76.3, 76.8
Tulane	(1909) 76.8;	(1917)	85.6
Johns		(1916)	87.8
Columbia University	(1916) 85.5;	(1917)	81.8
Jefferson Medical College		(1917)	75.2
Meharry Medical College		(1897)	75.3
University of Nashville		(1917)	75
Vanderbilt University		(1917)	80.6
University of Virginia

Book Notices

Practical Materia Medica and Prescription Writing, with Illustrations. By Oscar W. Bethea, M.D., Ph.G., F.C.S., Assistant Professor of Materia Medica and Instructor in Prescription Writing, Tulane University of Louisiana. Second Edition. Cloth. Price, $4.50 net. Pp. 562. Philadelphia: F. A. Davis Company, 1917.

The Prescription Therapeutically, Pharmaceutically, Grammatically and Historically Considered. By Otto A. Wall, Ph.G., M.D., Professor of Materia Medica, Pharmacognosy and Botany in the St. Louis College of Pharmacy. Fourth Edition. Cloth. Price, $2.50. Pp. 274, with illustrations. St. Louis: C. V. Mosby Company, 1917.

Pharmacy, Theoretical and Practical, Including Arithmetic of Pharmacy. By Edsel A. Ruddiman, Pharm.M., M.D., Professor of Pharmacy and Materia Medica, Department of Pharmacy, Vanderbilt University. Cloth. Price, $1.75 net. Pp. 267. New York: John Wiley & Sons, 1917.

The first edition of the volume by Bethea was reviewed in The Journal, Nov. 6, 1915, p. 1667, when the purposes of the book and the general treatment of the subject were described. In the second edition the book has been brought up to date, especially with reference to drugs in the United States Pharmacopeia. New ones have been added, and many dropped, "with a sigh of relief," it is said. In addition to naming all of the pharmacopeial preparations and describing many of them, prescriptions are given which illustrate the manner in which these are advantageously prescribed. Errors and incompatibilities are pointed out. There are clinical and general indexes. Attention might be called to a few errors in proofreading of the names of drugs and chemical formulas, and to the frequent occurrence of the split infinitive and other defects of style which have not been eliminated from this edition. Attention is properly directed by the author to the undesirability of the habit of prescribing proprietary drugs, but it is to be noted with reference to prescription writing, that after giving the Latin terminations of many drugs the author says: "They are always abbreviated, so it is suggested that a study of terminations is not necessary." This is a bad suggestion, as is the one that the prescriptions given in the book are in perfect form to be copied and sent to the duggist, a method of prescribing which should not be encouraged.

Leaving out the section on materia medica, Wall's book covers much the same ground in the matter of prescription writing, with examples, etc., as the book by Bethea, but it is more extended. Most interesting is the history, which it gives, of prescription writing from its beginning in ancient days. The author upholds process patents on proprietary drugs, and the specification of the products of a certain manufacturer in a prescription.

Ruddiman has given interesting, practical and useful statements of things the practicing pharmacist should know, but adapted more especially to the use of students. His book is intended to be supplementary to the information gained from the Pharmacopeia and the National Formulary.

Examination of Water, Chemical and Bacteriological. By William P. Mason, Professor of Chemistry, Rensselaer Polytechnic Insitute. Fifth Edition. Cloth. Price, $1.25. Pp. 186, with illustrations. New York: John Wiley & Sons, 1917.

In this new edition of a well known laboratory guide, there has been little change in the chemical analyses described; but the tests for "relative stability," free chlorin, and lime and soda values have been added. The bacteriologic methods have been rewritten to conform to the latest edition of "Standard Methods." Unfortunately the normal chlorin maps referred to in the text have been omitted. The illustrations have been materially improved over those in former editions. Amplification of Appendix A, discussing the interpretation of a water examination, would greatly increase the usefulness of the book for elementary students.

Medicolegal

When Right of Appeal to Courts Obtains

(Brown vs. Harris County Medical Society et al. (Tex.), 194 S. W. R. 1179)

The Court of Civil Appeals of Texas, in reversing a judgment that dismissed the plaintiff's application for injunctive relief against expulsion from the defendant society, says that the trial court sustained a general demurrer to the plaintiff's petition, and on his declining to amend the same, dismissed his suit on the ground that it appeared from the petition that the plaintiff had the right to appeal to the board of councilors of the state association, from the proceeding of the defendant society, and that such appeal made provision for adequate relief. The cause having been disposed of by demurrer, this court was not advised, nor was the trial court advised, otherwise than by the allegations of the plaintiff's petition, as to what provision was made for the trial and expulsion of the members of the defendant society, by its by-laws and rules. Therefore the court is unable to say whether or not the plaintiff was tried and convicted in accordance with the by-laws and rules of the association, or whether or not the appeal provided for would have afforded adequate relief, unless the court does know that in his petition the plaintiff alleged that he was tried on charges presented on the night on which he was tried and convicted; that he had no notice or knowledge of the existence of such charges until after he had presented his defense; and that this trial on such charges was contrary to and in violation of the by-laws and rules of the association. The court also knows that the plaintiff alleged in his petition that the provisions for appeal made by the association were wholly inapplicable and inadequate, and would not afford him any relief for the alleged unlawful conviction and expulsion. If the allegations of the plaintiff's petition were true, he had the right to resort to a court of equity for relief, and the trial court erred in holding to the contrary and dismissing his suit on demurrer; in other words, if the plaintiff's allegation that the board of councilors, the appellate body, had no power to review and reverse the action of the local society, in expelling the plaintiff, in the event they should find that he was not tried in accordance with the by-laws and rules of the association, was true, the appeal provided by the association was inadequate and would not furnish the plaintiff relief from such unlawful conviction and expulsion, and in such case he had the right to resort to the courts for relief. The trial court should have overruled the general demurrer, and have heard evidence as to the facts alleged with reference to the rules of the association governing appeals, and in the event the facts alleged were established, the court should have gone further and heard evidence as to whether the plaintiff was tried and expelled in accordance with the by-laws and rules of said association. It is well settled that where an association under its rules expels a member, such member must resort to, and must exhaust, the remedies provided by the association itself, through its constitution and by-laws, before applying to a court of equity for relief. But this court has found no authority for holding that where a member of a voluntary association has been convicted of an offense and expelled in violation of the rules and by-laws of the association, and where the by-laws and other laws of the association do not allow adequate relief by appeal from such conviction and expulsion, such member may not resort to a court of equity for relief. The court thinks the uniform holding of all courts is to the contrary.

12 Case of Pseudohermaphroditism. H. D. Purdum, Sykesville, Md.—p. 813.
13 Primary Carcinoma of Liver in Childhood; Report of Case. J. Forman, Columbus and J. S. Hattery, Manfield, Ohio.—p. 862.

1—4. Abstracted in The Journal, Oct. 13, 1917, pp. 1293 and 1294.

6. Abstracted in The Journal, Oct. 20, 1917, p. 1377.

7. **Carcinoma of Cervix.**—About sixty-five cases of this kind are now on record. Vander Veer points out that because carcinoma of the cervix does occur in a few cases following suprapubic hysterectomy, it is not a point in favor of a panhysterectomy exclusively. The dangers of a panhysterectomy are greater than the risk of a carcinoma occuring secondarily in the cervical stump and being promptly treated. A careful examination should be made of every cervix before the hysterectomy is performed, particularly in women who have borne children. In every case of hysterectomy, the patient should be advised to report promptly if there is any appearance of a vaginal discharge, a curettment done, and a laboratory examination made. Removal of the cervix per vaginam is certainly to be perferred to opening the abdomen in every case in which the disease has not progressed too far, as well as in cases having any discharge. Routine pathologic examination of the myomatous uterus at the time of operation should be done, and in this way unsuspected cases of carcinoma of the uterus, also of the cervix, will be discovered and the proper operation then performed.

8. Abstracted in The Journal, Oct. 27, 1917, p. 1466.

10. Abstracted in The Journal, Oct. 20, 1917, p. 1378.

11. **Study of Vulvar Carcinoma.**—The fifteen observations of vulvar cancer made by Taussig illustrate the great malignancy of cancer in younger individuals. Of special interest was the fact that of the five whose age was under 45 years, two had had operations that brought on artificial menopause and these two were by far the most malignant in this series. Previous pregnancies would not seem to be a factor in their development, for six of the fifteen women had had no children and three of them had never been married. The inguinal or femoral lymph glands were involved with certainty in nine of the fifteen women. Only one of these nine women is at present living and this one was operated on only four months ago so that the probability is that she also will die of a recurrence. Taussig says that the fact that no cancer was found in the lymph glands in some of these cases by no means proves that a small nest of cancer cells was not tucked away in some unexamined portion of the tissue removed. Clinical experience shows that in almost every case of vulvar cancer, even in the earliest stages the lymph glands are involved. Even after radical removal of the lymph glands with the vulvar mass, the chance for a reappearance of the cancer in the glandular system is three times greater than is the local recurrence.

27 Histopathology of Twenty-Six Cases of Carcinoma of Testicle. S. H. Geist and W. Thalhimer, New York.—p. 571.
28 University Hospital Shoulder Splint. S. Pope, San Francisco.—p. 581.
29 *Evaluation of Asepsis and Antisepsis. W. F. Fowler, Rochester, N. Y.—p. 583.

19. **Treatment of Septicemia by Transfusion.**—Five cases of transfusion of immune blood for staphylococcus infection are reported and analyzed by Hooker. In four the donors were immunized. The results obtained are decidedly in favor of the efficacy of immunized blood transfusion in chronic staphylococcus septicemias, and especially in those which complicate bone conditions. In this class of cases there is usually ample time to prepare a suitable donor by administration of vaccines, but if the anemia is pronounced no time should be lost in performing a preliminary transfusion of normal blood. In the acute infections, early blood cultures and an immediate start to immunize a donor are of the utmost importance. If urgent, it is best not to wait for full immunization but to give the first transfusion even after one dose of vaccines. If the patient has a fairly good blood volume with a high bacterial blood content, there should be no hesitation in removing a considerable amount of blood by venesection just before transfusion.

20. **Bacteria Within Sequestrums.**—In about 90 per cent. of the specimens of bone examined histologically by Taylor and Davies bacteria were seen lying well within the substance of the sequestrum, usually in nests within the canals or cell spaces. The organisms were recovered more frequently from the sequestrum than from the wound, suggesting a richer flora within the former. One point, however, is especially evident, and that is the greater incidence of the anaerobic group within the sequestrum. Gas-forming anaerobes developed nearly four times more often from the bone than from the wound, while spores were present six times more often. In no case were gas or spore-producing anaerobes recovered from the wound when not recovered from the sequestrum removed from it. The bone itself appears to be the most common site for the persistence of the anaerobic flora. Anaerobic bacilli are probably active factors in the disintegration of sequestrums within the wound. Anaerobic bacilli within the dead bone appear to be associated with the occurrence of "flares" after operations on bones. Flares occurred more frequently after sequestrectomy when the cases were over 120 days old than when the cases were under that age. The authors believe that it is probably impossible to kill by antiseptic treatment the bacteria within the dead bone. The object of treatment must be to remove this focus of infection. The sequestrums may be extracted by operation, or their dis-

appearance hastened by utilizing the solvent action of acid dressing solutions. The persistence of bacteria within the bone probably explains the infection which often follows bone grafts in old compound fractures, and indicates the advisability of postponing that operation as long as practicable.

21. **Diabetes Insipidus After Head Wound.**—Graham's case is of interest because it seems to bring additional support to the idea that diabetes insipidus is an expression of a disturbance of function of the hypophysis or its neighboring tissue.

22. **Traumatic Brachial Paralysis.**—The purpose of this paper is to confirm, by further clinical experience, the conclusion reached six years ago on this phase of traumatic brachial paralysis, that is, that the flail shoulder joint is the result of a dislocation and is essentially the cause and not the result of the paralysis. This is shown by the fact that the early operative removal of the flail shoulder results in a cure of the paralysis. If the paralysis and flail shoulder had been caused by a rupture of the brachial plexus, recovery would not have followed, uniformly, treatment restricted to the shoulder joint. According to Thomas's experience, in most cases of traumatic brachial paralysis the shoulder joint is not in the least flail, but on the contrary exhibits limited movement and pain when movement is made. In view of the large number of cases of obstetric palsy reported, hundreds of them in recent years, Thomas is inclined to doubt its occurrence. If it does not occur it then becomes necessary for those who account for the obstetric paralyses by an injury of the brachial plexus to explain the absence of flail shoulder in this class of cases.

26. **Enterostomy in Healing of Fistula.**—Mayo proceeds as follows: A low-lying loop of distended bowel is elevated into the incision. A segment is freed of gases or fluids and controlled by rubber-covered forceps applied above and below mesentery a purse-string suture of silk is applied in a diameter of half an inch. The bowel is perforated in the center of the point selected for perforation. At a point opposite the the purse string by a knife or cautery. A catheter, size 10 or 12, is inserted several inches into the intestine and held in place after the purse string is tied, by perforating its side with the same needle and tying it into place. Two successive purse-string sutures may be applied by the Stamm-Kader method, but the procedure most satisfactory is that of Witzel, that is, depressing the catheter into the wall of the bowel and suturing together the folds thus formed over the catheter for a space of an inch and a quarter. When the operation is made as a jejunostomy for feeding or for intestinal obstruction in children the Coffey method of incising the peritoneal and muscular layers of the bowel at the point of depressing the catheter into its wall conserves the lumen of the intestine, the tube being placed between the mucosa and the wall of the intestine, and the peritoneum and muscle being approximated over the catheter. This method is rarely followed by a fistula. For additional security and also to favor closure of the opening, pass the catheter through the perforated omentum and then for fixation include the parietal peritoneum, the omentum and the intestine in three sutures. This method maintains a movable, even if adherent, intestine and the omental graft aids in closing the bowel opening by granulation.

29. **Evaluation of Asepsis and Antisepsis.**—Fowler's investigation of the value of various antiseptics and methods of antisepsis discloses abundant clinical evidence of the efficacy of iodin in skin sterilization, this evidence being corroborated by laboratory findings; the germicidal action of mercuric chlorid is too slow to be of value in sterilization of the skin. Eternal vigilance is the price of asepsis.

36 *Studies on Blood Sugar. L. Hamman and I. I. Hirschman, Baltimore.—p. 761.
37 Kidney Function in Diabetes Mellitus. R. Fitz, New York.—p. 809.

30. **Renal Function in Gout.**—McClure is of the opinion that the apparently frequent occurrence of decreased renal function in cases of typical gout justifies a word of caution against assuming that the faulty excretion of uric acid and of other nitrogenous substances when found is due to derangements in metabolism. The gouty kidney is often functionally deficient, hence the faulty elimination of exogenous uric acid and of other nitrogenous substances by gouty persons may be the result of depression of the functional power of the kidneys. While renal retention explains many of the anomalies occurring in the excretion of uric acid and of other nitrogenous substances in gout, nevertheless this does not explain the nature of gout, nor does it preclude the possibility of there being an underlying perversion of metabolism. The purpose of this discussion has been to emphasize the facts that (1) many of the findings which have heretofore been considered due to disturbances of nuclein metabolism in gout may be explained as the result of renal inadequacy, and (2) that the theories concerning the etiology of gout remain hypotheses without satisfactory experimental bases.

34. **Ventricular Fibrillation in Man with Cardiac Recovery.**—A case is reported by Robinson and Bredeck in which the patient showed marked cardiac insufficiency and had three attacks of cardiac syncope. During one of these attacks an electrocardiogram was obtained which is typical of ventricular fibrillation. The patient lived thirty hours after this syncopal attack, and numerous electrocardiograms were obtained during this time. One immediately after the intravenous injection of strophanthin showed a deranged cardiac mechanism similar to that observed experimentally by Levy and Lewis during the so-called state of potential fibrillation. The abnormal forms of ventricular complex which occurred frequently, were such as to indicate that there was a derangement of intraventricular conductivity. This may have been the prime factor in the production of the ventricular fibrillation. The occurrence of ventricular complexes indicative of derangement of intraventricular conductivity should be taken as contraindication for the use of drugs such as chloroform, epinephrin and strophanthin, which predispose the heart to ventricular fibrillation. The foregoing case is the first example of cardiac recovery from well established ventricular fibrillation that has been observed in man.

46 *Adenomyoma of Rectovaginal Septum. T. S. Cullen, Baltimore.—p. 343.
47 *Hematomas of Ovary, Including Corpus Luteum Cysts. E. Novak, Baltimore.—p. 349.

45. **Fifty Uteri Removed at Cesarean Section.**—During the past twenty years Williams has had occasion to amputate the body of the uterus supravaginally and to treat the stump extraperitoneally in fifty cases following delivery by cesarean section. In each instance the specimen has been preserved and subjected to careful histologic examination. The study of this comparatively large material has yielded important information concerning a number of questions; more particularly concerning the mechanism of the separation of the placenta and of the fetal membranes; the amount of decidua retained immediately postpartum; the vascular changes at the placental site; the retraction of the uterine muscle; the occurrence of ascending infection in patients who had been long in labor, or who had been repeatedly examined by persons neglecting rigorous hand disinfection; and finally concerning the characteristics of the cicatrix resulting from previous sections, and its bearing on the correctness of the dictum—"Once a cesarean always a cesarean." But, Williams says, that the evidence at his disposal indicates that the healing of cesarean section wounds is generally satisfactory, provided the convalescence has been normal, and ordinarily does not call for a repetition of the procedure unless definitely indicated by the existence of extreme disproportion or some other conditions. On the other hand, in patients in whom the convalescence has been abnormal, it is probable that the cicatrix will be greatly thinned out and will offer a locus minoris resistentiae. In such cases, a repeated cesarean section may be indicated for the express purpose of avoiding a subsequent rupture. Williams' experiences, however, shows that this is not inevitable and that even should it occur, satisfactory results should follow prompt operation. For practical purposes, therefore, Williams concludes that the behavior of the cicatrix can be regarded with equanimity provided the previous convalescence has been normal, but when it has been disturbed there is a reasonable probability of the occurrence of rupture, and that such patients should be kept under the closest observation during the last months of a succeeding pregnancy.

46. Abstracted in The Journal, Aug. 5, 1916, p. 401.

47. **Hematomas of Ovary, Including Corpus Luteum Cysts.**—A careful study of the menstrual histories of the cases on which Novak's paper is based shows that the hemorrhage which cause follicular hematomas occurs characteristically at or near the supposed time of ovulation, that is, between the seventh and sixteenth days of the menstrual cycles. The bleeding of corpus luteum origin, as might be expected, occurs later, being apparently only an exaggeration of that normally occurring in the stage of vascularization. There is no characteristic menstrual history associated with the presence of hematomas in the ovary.

83. **Determination of Calcium in Blood.**—The authors suggest the precipitation of calcium as oxalate directly in the filtrate from biologic fluids after removal of protein, the final estimation being carried out by a refinement of the permanganate titration method. In this paper is presented in greater detail the procedure which experience with this method has suggested as well as data with regard to the accuracy of estimation.

84. **Calcium Content of Blood Serum.**—Data are presented by the authors with regard to the calcium content of human blood serum in certain pathologic conditions, particularly nephritis, as well as of the blood serum of normal men. In the normal cases values lying between 9 and 11 mg. of calcium per hundred cubic centimeters were obtained. In nearly all of the pathologic conditions studied, including cases in which the blood clotted with extreme slowness, a similar range was observed, indicating a great constancy of this element in the blood serum. Distinct decreases were

noted in cases of hematogenous jaundice, eclampsia, pneumonia and particularly uremia. In several cases of uremia increases in serum calcium were noted on improvement in the clinical condition and following administration of calcium lactate. The urinary calcium excretion in severe nephritis was found to be low and calcium lactate administration brought about but slight absolute increases. In cases in which marked general edema occurred, with or without nephritis, the excretion of calcium was unaffected by increased ingestion. In a case of pernicious vomiting of pregnancy with severe acidosis, alkali administration decreased calcium excretion to 8 per cent. of its original value. It is pointed out that calcium determinations on whole blood are of little value unless the relative volume of plasma and corpuscles is known.

85. **Pellagra Producing Diets.**—McCollum and Simmonds believe that there are two deficiency diseases in the sense in which Funk employed this term. One of these is polyneuritis, which Funk recognized. This is due to a lack of an adequate supply of the unidentified water soluble B which is abundant in all natural foodstuffs but is practically absent from purified starch, polished rice, sugars, and all fats of both animal and vegetable origin. The other is a syndrome in which the two most prominent features are emaciation and xerophthalmia. Scurvy, pellagra and rickets can be accounted for by errors in the diet without assuming a protective substance for each of them.

87. **Calcium and Magnesium in Blood Serum.**—By the methods described by Marriott and Howland it is said to be possible to determine calcium and magnesium in 2 c.c. samples of serum with a maximum error of less than 5 per cent., a degree of accuracy entirely sufficient for the purposes for which the methods were devised. The methods depend on the fact that solutions of ferric thiocyanate are decolorized by oxalates and by phosphates. Calcium is precipitated as the oxalate and magnesium as the ammonium magnesium phosphate; the precipitates are dissolved in acid and added to solutions of ferric thiocyanate, the degree of decolorization resulting being determined by comparison in small Nessler tubes.

88. **Phosphates in Blood Serum.**—This method was devised by Marriott and Haessler in order to determine whether or not a retention of inorganic phosphates, with a resulting increase of these substances in the blood serum, occurs in patients suffering from certain types of nephritis. Results obtained by the use of the method in such cases have already appeared. The method depends on the decolorization of solutions of ferric thiocyanate by an acid solution of ammonium magnesium phosphate. The phosphates of the serum are precipitated directly by means of magnesia mixture.

89. **Iron as Antidote to Cottonseed Meal Injury.**—Feeding experiments with pigs showed that iron salts have a decidedly beneficial action in preventing cottonseed meal injury. Much larger quantities of meal are consumed, deaths have been postponed or averted, and better gains have been made when an iron salt is added to the feed. The suggestion is made by Withers and Carruth that the iron salts combine with, or facilitate oxidation of the harmful substances in cottonseed meal. By thus controlling the toxic factor, it is shown that cottonseed meal injury is not due to a lack of vitamins or to deficiencies in calcium, sodium and chlorin—which ash analyses might lead one to suspect as the limiting mineral factors in a diet of cottonseed meal and corn.

6 *Early Operative Treatment of Penetrating Gunshot Wounds of Chest. F. J. Hathaway.—p. 582.
7 *Treatment of Gunshot Wounds of Elbow Joint; Plea for Primary Excision. C. M. Moullin.—p. 583.

1. **Treatment of Injuries to Peripheral Nerves.**—Moynihan summarizes his experience in this field of work as follows: The earliest examination should be made of all wounds in which division of a nerve trunk is probable. If at the casualty clearing station such a lesion is found, end-to-end suture should be adopted forthwith. This is more likely to be possible in cases in which primary suture of the wound, after excision is found practicable. If secondary suture of the wound after the Carrel-Dakin method has been practiced is to be undertaken, the union of divided nerves should be secured at the same time. If these methods have been attempted and have failed, they do not prejudice the later union of the nerve. On the contrary, they probably ensure that an easier and more satisfactory operation can then be practiced. Throughout the whole period before late nerve suture is attempted the strictest attention must be paid to the relaxation and nutrition of all paralyzed muscles, to the maintenance of suppleness in all joints moved by these muscles, and to the preservation of the integrity of the skin. Operations on nerve trunks demand the most scrupulous observance of the ritual of asepsis. There must be the greatest gentleness of manipulation; the nerve must not be injured by instruments or by the surgeon's finger; it must not be separated from its sheath or disturbed overmuch from its bed; it must not be chilled or allowed to dry. All sutures must be of fine catgut, and introduced with most punctilious accuracy. Axial rotation of the nerve must be avoided. The cut ends of the nerve before approximation must show clearly the fibers of which the trunk consists. Nerve grafting is of little or no value; nerve anastomosis is to be sharply condemned; the turning down of flaps from the nerve to bridge a wide gap is useless. Tendon transplantation is of great value in cases in which nerve suture is impossible, or has given a result not entirely satisfactory.

2. **Surgical Treatment of Wounds of Chest.**—Wounds of the chest, as seen at an advanced casualty clearing station, are classified by Anderson into two main groups from the point of view of prognosis: Group A: 1. Entrance and exit bullet wounds. 2. Entrance and exit shrapnel-ball wounds. 3. Wounds caused by small fragments of high explosive missiles. As a general rule these cases do exceedingly well if treated expectantly and aspirated or operated on when occasion demands. They can usually be evacuated to the base in from three to ten days, and the ultimate results are good. Of course, in a certain proportion of such cases there is sufficient visceral injury to cause immediate or early death, but, as they seldom reach the casualty clearing station, they do not come within the scope of this paper. Group B: 1. Wounds caused by large irregular fragments of high explosive shell which have lodged in the thorax. These are almost always associated with (*a*) clothing and infection carried in, and (*b*) open sucking wounds of the chest wall. 2. Tangential wounds of the thorax, enfilading the ribs and driving portions of bone, etc., into the pleura and lung. 3. Entrance and exit bullet wounds in which the exit wounds are explosive in character.

If treated expectantly only a very small percentage of Group B 1 reach the base, and many of those that are evacuated appear to die from the complications of their wounds. In Group B 2 and 3 the prognosis is usually not so severe, but an unduly large percentage develop an infected hemothorax unless the chest wall wound is treated energetically. In the latter group the prognosis, when no operation is performed, is always worse in wounds of parts where there is a liberal muscle covering, for example, in the scapular region. The patients in Group B usually have died hitherto at the casualty clearing station from sepsis and exhaustion, and it is this group of cases which demands more vigorous surgical intervention.

3. **Id.**—The principles Roberts and Craig have tried to follow in the treatment of chest wounds recently dealt with have been: operation at the earliest possible moment, free excision of all infected tissues, removal of the foreign body and cleansing of the pleural cavity or wound of the lung, followed by accurate suture of the lining membrane and tissues over it, whenever possible without drainage. Drainage of the pleural cavity has been employed only when one or other of these principles could not be fulfilled, for example, when a large foreign body, with infection around it, could not be removed. When anaerobic infection of the superficial muscles is present the wound is left open to an extent corresponding to the area of the infection, for example, in the case of a wound of the back when the more superficial muscles alone are infected it is possible to suture the pleura and leave the superficial part of the wound freely drained. There does not seem to be grave objection to washing out with, and possibly leaving inside the pleura, a few ounces of a nonirritating antiseptic, such as alkaline solution of sodium hypochlorite (Dakin's) or other similar solution, but the necessity for this is by no means established.

6. **Id.**—The ideal methods of modern war surgery are (1) early operation, (2) complete excision of wound and damaged tissues, (3) removal of metal fragments and clothing, (4) mechanical cleansing of wound (the use of strong antiseptics is to be avoided), and (5) complete suture of wound. Provided one can get early and complete operation, there is far more danger from secondary than from primary infection. The treatment of wounds of the chest, therefore, follows the same lines as those of the abdomen, head, knee, or other joints; they require just as early operation, and, Hathaway says, the results are just as good.

7. **Treatment of Gunshot Wounds of Elbow Joint.**—The results of primary excision of the elbow joint, according to Moullin, are wonderfully good, provided sufficient bone is removed; that is to say, the lower end of the humerus just above the level of the epicondyles, the whole of the head of the radius and the ulna at the same level. Even if the conditions are such that the wound is already infected, the drainage is so free that a serious degree of sepsis can usually be avoided, and there is not that enormous mass of callus thrown out, binding everything together and locking the fragments so that they cannot move. Owing to the necessity of reeducating the muscles of the forearm, which have been separated from their attachments, it may be twelve months before recovery is complete, but the fingers and wrist can be used after the first few weeks, and, if a suitable splint is provided, the elbow as soon as the wound is sound.

16 Rations in Relation to Disease in Mesopotamia. W. H. Willcox.—p. 677.
17 *Influence of Hypnotic Suggestion on Inflammatory Conditions. J. A. Hadfield.—p. 678.
18 Case of Epilepsy Cured by Removal of Calcareous Intracranial Tumors. T. Thompson and A. J. Walton.—p. 679.

11. Nitrous Oxid and Oxygen with Rebreathing in Military Surgery.—This paper is an attempt to procure a more extended use of gas and oxygen with regulated rebreathing in major surgical procedures, and especially in the treatment of wounded. Boyle points out that this anesthetic is nontoxic, and therefore there is less strain put on to the patient, seeing that he does not have to eliminate the drug, be it ether or chloroform, from his system. Moreover, there is no shock after gas and oxygen. However, this combination of anesthetics is not one to place in the hands of the careless or inexpert—it requires skilful administration, and if used carelessly will inevitably lead to disasters. The method is unsuited when absolute relaxation is required all the time; in some abdominal cases, for instance, gallbladder operations. There have not been any fatalities among 711 cases.

14. Repair of Crucial Ligaments.—The principle of the operation devised by Groves consists in forming a new anterior crucial ligament from the iliotibial band and a new posterior ligament from the tendon of the semitendinosus. In each case the new ligament retains its upper attachment in the thigh and is threaded through new canals bored in the femur and tibia, and is sewn to the outer surface of the latter bone.

15. War Wounds Treated with Proflavine.—As tested by the authors in the treatment of a series of recent wounds, there appear to be no differences in the properties of the two substances acriflavine and proflavine.

17. Hypnotic Suggestion.—Hadfield cites a case of blisters on the skin caused by hypnotic suggestion.

19. Leukocytic Count in Beriberi.—Differential leukocytic counts in forty-two cases of clinically recognized beriberi seen at the Shantung Road Hospital, Shanghai, during the year 1912 were made by Chun. The differential count published by the author as being that of a normal Chinese is as follows: finely granular oxyphil, 58.0 per cent.; coarsely granular oxyphil, 5.7 per cent.; basophil leukocyte, 0.6 per cent.; hyalin, 9.8 per cent.; and lymphocyte, 25.3 per cent. The differential count obtained in forty-two cases of beriberi was as follows: finely granular oxyphil, 57.4 per cent.; coarsely granular oxyphil, 5.2 per cent.; basophil leukocyte, 0.4 per cent.; hyalin, 19.5 per cent., and lymphocyte, 17.2 per cent. It will be noted that the hyalin cells average as high as 19.5 per cent., whereas the normal figure among the this notably high percentage of the hyalin cells may serve Chinese ought to be 9.8 per cent. The author suggests that as a help toward the diagnosis of beriberi in difficult cases.

40 Nervous Lesions after War Wounds of the Head. H. Gougerot.—p. 301.

37. Roentgenotherapy of Tuberculous Peritonitis.—Weil remarks that of all the various methods of treating tuberculous peritonitis that have been applied to date, systematic utilization of sunlight and sea air seem to have the most testimony in their favor. But both require the suitable environment which is within the reach of comparatively few. On the other hand, with the roentgen rays we can apply the chemical rays anywhere, even to outpatients. He has been applying roentgenotherapy systematically since 1914, using large doses of very penetrating rays, filtered. Some of the children had the fibrous form of peritonitis and some the form with ascites. In every case in which there was not already generalization of the disease in the lungs or pronounced cachexia, a complete cure was rapidly realized, with complete restoration of the general health. He uses a Coolidge tube, a 5 mm. aluminum filter, a 20 cm. spark, and a 1.5 or 2 milliampere current. The exposures are repeated about monthly, but he reduces the strength a little each time to ward off skin trouble. This technic does not entail radiodermatitis nor generalization of the tuberculosis. After the first series there may be a recrudescence of the fever and persisting malaise, but this reaction was never serious in his experience, and he never allowed it to interfere with his giving the effectual dose of 12 or 14 H units in the course of four successive days on the four quarters of the abdomen. In case of much debility the series can be fractioned to spread out over ten or twelve days.

46 Traumatic Deadening of Peripheral Nerves. P. Descouts.—p. 572.
47 Present Status of Treatment of Gonorrhea in the Male. P. Chevallier.—p. 573.

41. **To Overcome Effect of Stiff Ankle.**—Ducroquet gives serial views showing the mechanical principles involved in the disturbance with ankylosis of the ankle joint. It can be corrected in large measure by wearing a heel that brings the foot and leg into an angle of 70 degrees instead of the right angle with the naked foot. The knee and body must be bent to correspond, but this is not enough to attract attention.

44. **Test Tachycardia.**—Aubertin regards as extremely instructive the varying degrees of shortness of breath and acceleration of the heart beat induced by a given muscular exercise and by the change from a reclining to an erect position. The pulse is counted reclining, and again standing. After the exercise, it is counted standing still and reclining again, allowing a given interval between the counts. A number of tracings are given for comparison.

45. **Improvised Mask.**—Savariaud fits a bag of rubber cloth of the mackintosh type loosely over the patient's face. It is held in place by an elastic band, of garter elastic, passing under the chin and over the top of the head. The cloth piece is 50 by 70 cm. in size, and is doubled over and the edges sewed together to make a bag 35 cm. deep. A hole large enough to admit the tip of the finger is made to the right of the nostrils with a counter opening on the other side. The pressure from the elastic band on the suprahyoid region prevents the tongue from dropping back into the throat. The ears show beyond the elastic band, and as long as they are pink and the patient is breathing regularly, all is well.

60 The Inorganic Nervous Affections after War Wounds Are the Same as the Hysterotraumatisms of Peace. J. Ferrand.—p. 239. To be continued.

54. **Epidemic Meningitis with Purpura.**—Netter remarks that the peculiar gravity of epidemic meningitis with purpura calls for early intraspinal treatment with a polyvalent serum made from as many strains of meningococci as possible. By this means the mortality in France has been kept down to 24 per cent. while British statistics show a mortality of 60 per cent. The purpura may precede the meningitis, and may even develop without meningeal symptoms at any time. The purpura indicates the generalization of the infection, as the meningococcus is found in the skin lesions and in the blood, and there may be involvement of the joints or myocardium, or iridocyclitis.

55. **Irritation of Spinal Nerve Roots.**—Leri reports in detail [illegible]ur cases in which the pains and loss of cutaneous sensibility [illegible]tched along the neck, shoulder and arm, corresponding [illegible]vation from the cervicobrachial spinal nerve roots. [illegible] by [illegible] in the region were also attenuated or lost [illegible] ere was paralysis later, with atrophy of the [illegible]t on the brachial plexus. Syphilis could not [illegible]use [illegible]d there was nothing to suggest tuberculosis [illegible] ge[illegible] four men, but the trouble had commenced with pains in the spine suggesting rheumatism. Leri discovered tender points in the region of the sacrolumbar roots in eighteen or twenty-four cases of ordinary sciatica; in thirteen there was decided lymphocytosis in the cerebrospinal fluid.

56. **Acute Liver-Kidney Insufficiency.**—Merklen gives the details of fifteen cases in which symptoms indicated that the liver and kidneys had suddenly stopped working properly on account of some toxic-infectious influence. In nine cases the disturbances proved rapidly fatal, but in the others the jaundice and uremic symptoms with oliguria and even anuria yielded when copious diuresis was realized, and the men recovered. The condition was much graver to start with than in other forms of infectious jaundice, and estimation of the urea content is the guide to the prognosis. The one thing in treatment is to get the kidneys to working extra freely and keep this up.

59. **Influence of Hemorrhages on Glycemia.**—Lépine relates that a loss of blood corresponding to 1 per cent. of the weight of the animal is almost always followed by hyperglycemia in the healthy animal. Repeated losses of blood may exhaust beyond chance of this recuperating reaction.

Correspondenz-Blatt für Schweizer Aerzte, Basel

October 13, XLVII, No. 41, pp. 1361-1392

61 Reconstruction of the Jaws after War Wounds. (Chirurgisch-zahnärztliche Kieferbehandlung.) H. Matti.—p. 1361. Egger.—p. 1365.
62 *Tumors of the Knee Joint Capsule. J. Züllig.—p. 1368.

62. *Tumors of Knee Capsule.*—Züllig reports a case of giant-cell xanthosarcoma, growing from the synovial membrane of the knee, with a clinically mild course. The patient was a woman of 34 who for ten years had had occasional pains in the right knee with intermissions up to four years. For the last year there had been an effusion at times. It subsided under bed rest and moist heat. The movements of the joint were free, but a movable tumor could be felt close to the patellar ligament. Roentgenoscopy showed the bones normal in the joint but the operation revealed three small tumors in a group and a small fibrous growth, all starting in the synovialis and easily removed. About six months later a fat tissue tumor was removed from the fat tissue around the joint. Histologic examination showed that the first tumors were of the xanthosarcoma type. The patient has had no further disturbance from the knee during the year since. Aside from cases of lipomas, Züllig was able to find only seventeen cases of a tumor of a joint capsule on record. In the eleven sarcoma cases all but three were women. In eight cases the entire capsule was infiltrated with the chondromatous or sarcomatous tissue. In only five of the sarcoma cases was there an isolated tumor. The course was from one to two years except in his case, but in all it was emphasized that there had been no trauma of the knee. The age of the patients ranged from 18 to 39. In one case of small-cell, round-cell sarcoma repeated recurrences required operative measures, and finally the leg was amputated. A myeloid sarcoma in one case has shown no signs of recurrence during the eight years to date. Differential diagnosis is usually by exclusion, the absence of trauma and of pathologic roentgen findings excluding meniscus injury, loose bodies, etc. With round-cell sarcoma, circumscribed excision is not radical enough, but with myeloid and giant-cell sarcomas this seems to be enough under expectant supervision, with repeated roentgen control. Diffuse sarcomatosis and tuberculosis have much in common, but with tumor the use of the knee may be more restricted while, on the other hand, there is not the extreme atrophy of muscles as with tuberculosis. There is little or no pain with sarcomatosis, and no friction sounds as the joint surfaces are intact, and no abscess and fistula production as is liable with a tuberculous knee. Analogous tumors in tendon sheaths are benign; in Spiess' four cases the interval before operation was one, five, twelve and twenty-two years.

67 *Malignant Papilloma of Maxillary Sinus. G. Bilancioni.—p. 353.
68 Malignant Edema without Gas Production. I. Scalone.—p. 374. To be continued.
69 *Technic for Amputations. G. Lerda.—p. 378. Commenced in No. 7, p. 310.
70 *Tumors of the Mesentery. P. Gilberti.—p. 386.

64. **Capillary Drainage of Wounds.**—Canestro keeps up a constant irrigation of the wound by means of three or more strands of wicking brought down from the irrigator and, after passing through the wound, brought down into a jar below the plane of the wound. This ensures continuous capillary irrigation and drainage. If neutral solution of chlorinated soda is used as the irrigating fluid, the secretions in the wound become thoroughly evacuated by this capillary drainage after a certain time, while the simplicity and ease of this technic commend it. A pad of nonabsorbent cotton is laid over the wound, the skin around protected with gauze impregnated with petrolatum. The nurse can see at a glance by the aspect of the efferent wicks that each is working properly. If the wicking is too short to run the entire distance, the wicking entering the wound and that fitted in its depths and conveying away the secretions can be separate pieces.

66. **Pernicious Malaria Simulating Tetanus.**—The case described emphasizes anew that in a malarial district, whatever the symptoms, the possibility of their being the work of malarial infection alone should never be forgotten.

67. **Malignant Nasal Papilloma.**—The malignant growth involved the right maxillary sinus and half of the nose of a man of 42, and there was recurrence in the lacrimal sac after its apparently successful removal. In another case in a woman of 56 the cancer involved all the right nasal cavities including the lacrimal sac. The microscopic findings are compared with similar cases on record.

69. **Technic for Amputations.**—Lerda here concludes his long study of the indications for different technics with various traumatic lesions with an appeal to save every possible scrap of skin, muscles and tendons. The geometric or esthetic aspect of the stump should be absolutely disregarded, and every effort made to maintain intact and vital all parts of the limb that permit this, when operating close to the firing line. The reduced resisting powers of the tissues and the omnipresent infection impose the necessity for the simplest technic, without attempting to suture. Cinematic amputations, such as Vanghetti has been preaching for twenty years, seeking to utilize the power still left in the stumps of the muscles, forming loops out of them, should be reserved till later. Even with a favorable environment for this complicated surgical work, it is often hampered by the difficulty of finding muscles and tendons long enough to make the loops and cross loops necessary for the purpose, and enough skin to line the tunneled loops.

70. **Ileus from Mesenteric Fibroma.**—Gilberti traces the history of mesenteric cysts back to 1507, but Morgagni in 1760 was the first to report obstruction of the intestine by a mesenteric cyst. In a personal case described, the pure fibroma had not caused any appreciable symptoms until suddenly obstruction of the intestines produced a severe set of disturbances. Probably some unusual accumulation of feces or gas had combined with the movable tumor to occlude the passage. There was no suspicion of the exact cause of the ileus until the operation revealed the mesenteric site of the tumor. The latter had been discovered several months before, immediately after an abdominal contusion.

76 Present Status of Treatment of War Wounds of Peripheral Nerves. G. Moscati.—p. 959.

73. **Parakinesia after War Wounds.**—Ricca applies this term to deviation from normal of the volitional motor functioning of certain groups of muscles after healing of a war wound. He cites a number of examples of these unintentional by-movements, and emphasizes the importance of breaking up these bad habits as soon as they show themselves. Once well established, the parakinesia may prove quite rebellious. Treatment is by training, with the usual measures for overcoming a tendency to tics of any kind.

Tumori, Rome

June-September, V, No. 3, pp. 229-356

77 *Experiences with Rat Sarcomas. G. Serafini.—p. 229.
78 *Preceding Injury of Tissues as a Factor in Development of Experimental Tumors. G. Fichera.—p. 258.
79 *Bone Metastasis of Hypernephroma. G. D'Agata.—p. 272.
80 *The Anatomic Findings and Outcome after Resection of the Stomach. G. Fichera.—p. 305. Continuation.

77. **Rat Sarcomas.**—Serafini relates that in resecting part of the spleen in a patient with malignant disease of the spleen, he was obliged to resect the splenic artery. Two years have passed to date without a sign of recurrence. This suggested that possibly the shutting off of the splenic vessels was responsible for the unexpectedly favorable outcome. But a long series of experiments on rats refuted this assumption, these rats dying rather sooner than the controls. Other factors must have been responsible in the clinical case mentioned. Further experiences on rats immunized with repeated small injections of spleen tissue or sterilized sarcoma tissue, either promoted the growth of the malignant tumor or had no effect. Injection into the tumors of an emulsion of lecithin seemed to sensitize the growths to the action of the roentgen rays. The sarcomas also showed a moderate inhibition of growth after treatment with rat serum that had been exposed in vitro to the action of the radium rays. But fragments of sarcoma exposed to radium seemed to give prompter and larger growths when the rats were inoculated with them than when the scraps had been exposed to roentgen rays. Inoculation of sarcoma tissue directly into the knee never induced a sarcoma at this point.

78. **Preceding Injury of Tissues as Factor in Development of Experimental Tumors.**—Fichera protests against the conclusions drawn by Pentimalli from a series of negative experiences in this line.

79. **Metastasis of Hypernephroma.**—D'Agata's patient was a man of 56 who six months before had noticed a bunch in the parietal bone. Indolent at first, during the last month it had increased in size until it was as large as a hen's egg. The tumor excised was of the suprarenal type of tissue, and D'Agata reviews the literature on the subject of hypernephromas and their metastasis in bones. This latter usually occurs between the ages of 40 and 60; only one case is cited in a younger woman. It has usually been diagnosed as a tuberculous affection until the microscope revealed its true character. The discovery of multiple tumors in an adult should always suggest the possibility of metastasis from hypernephroma; Albrecht advises a lumbar exploratory operation on this basis alone. The bone metastasis may precede clinical manifestations of the primary tumor, as in the case reported. D'Agata not only advises extirpation of the metastasis but insists that the primary tumor should be sought and removed and its site given roentgen exposures. Removal of the bone metastasis alone does not seem to have improved the prognosis in any of the cases on record, the primary tumor continuing its malignant course unmodified.

80. **Resection of the Stomach.**—In this instalment of his monograph, Fichera gives the operative findings and the outcome years later in six cases of gastric ulcer and forty-nine of gastric cancer.

83 Myxosporidium of Brazilian Fishes. A. M. da Cunha and O. da Fonseca.—p. 321.
84 Ancient and Modern Views of Syphilis. D. Speroni.—p. 325.

September 29, No. 39, pp. 329-336

85 *Spirochete of Hemorrhagic Jaundice in Rats at Rio. H. de B. Aragão.—p. 329.
86 *Suppuration in the Urinary Apparatus of Infants. N. Gurgel.—p. 330. Commenced in No. 38, p. 321.

81. **Pulmonary Mycosis.**—Magalhães relates that a young man developed mycosis of the lungs, fatal in a little over thirty days, and he knows of three other cases with a similar acute course. In some of the chronic cases he has encountered, the affection flared up into an acute phase, promptly fatal in more than one case. Left untreated, this pulmonary oidiosis is always fatal. The temperature curve is characteristically irregular, and there are signs of softening and breaking down of the parenchyma in the lung. Treatment with potassium iodid is decisive. The septicemia is alike in man and animals. The rabbit is as susceptible to inoculation with the oidium as the guinea-pig to tuberculosis. In macacus monkeys the oidium penetrated the intact mucosa of the mouth and nose.

85. **Spirochete in Rio Rats.**—Aragão reports finding in rats at Rio de Janeiro the spirochete described by Inada and Ito as the *Spirochaeta icterohemorrhagiae*, by the Germans as the nodose spirochete, and by Noguchi as the *Leptospira icterohemorrhagiae*. Kidney tissue from the rats was injected into six guinea-pigs, and one died the tenth day with intense jaundice and hemorrhagic foci in lungs and stomach, epistaxis and edema. Emulsions of liver and blood from this guinea-pig reproduced the same disease when inoculated into six others. Clinical cases of infectious jaundice have been described recently in northern Brazil, but the source of the infection could not be discovered in suspected human beings. The discovery of the spirochete in rats at Rio throws more light on the subject.

86. **Suppuration in Infant's Urinary Apparatus.**—Gurgel remarks that the infant's yellowish pallor and restlessness are the first symptoms that call the parent's attention to the trouble. The mucous membranes are blanched, and the child has no desire to eat. With fever in an infant the ear and the urine should be examined at once, but in practice very few take the trouble to examine the urine. He declares it is as important for the infant as for the adult. If not obtainable otherwise, he draws some urine with a catheter. In about 40 per cent. of the cases of fever in infants for which no cause is manifest, pyelitis is responsible, and in about 95 or 98 per cent. of the nontuberculous cases the colon bacillus is found. In the majority of cases the infection of bladder or kidneys has spread from the bowels, possibly by way of the lymphatics. In his experience there was usually a preceding influenza, measles or tonsillitis, and, in one case, paratyphoid infection; in all there was a history of intestinal upset. The pyelitis or pyocystitis generally develops insidiously and runs a protracted course. Left untreated, serious damage may result while the course is benign when the pyuria is discovered early and treatment applied at once. He has obtained excellent results in treatment of pyelitis in infants with methylene blue alone, injecting it into the rectum in a 1, 2 or 3 per thousand solution, twice a day. It generally is eliminated in from thirty to ninety minutes. In three or four days the fever drops and the pus disappears from the urine. The child cannot be deemed cured until repeated examination at varying intervals confirms the absence of pus from the urine. He reports eight cases in detail. In some cases, salol also was given, but the results were equally good with the methylene blue alone. In another case the *Bacillus lactis-aerogenes* was cultivated from the urine, and it induced in guinea-pigs congestion of the intestines and hemorrhages in the omentum.

94 The Fight against Tuberculosis in Argentina. E. R. Coni.—p. 288.

91. **Plantar Tibialis Reflex.**—Obarrio gives an illustration showing the dorsal flexion, adduction and inward rotation of the foot when the plantar reflex was elicited in a woman with spastic paralysis, negative Babinski, Gordon, Schaffer and Oppenheim signs, while the Strümpell was positive. The muscle showing the reflex action was the tibialis anticus. He has encountered it also in other cases of organic lesions with negative Babinski.

104 Paroxysmal Tachycardia with Hydatidiform Mole. P. L. Marcos.—p. 773.

102. **Suction Extraction of Cataract.**—Barraquer's success in extracting cataract in the capsule by vacuum suction has been mentioned in The Journal (June 9, 1917, p. 1789). He here gives a historical review of cataract operations, with illustrations showing the Daviel and Smith technics and his own method. The latter does not require any pressure but merely draws the lens out in toto by vacuum suction through a shallow cup applied to the lens. He also gives illustrations of different apparatus for inducing the vacuum by electricity or a water jet pump. The cataract extractor itself projects from a syringe-like instrument held in the hand like a pen, the thumb controling a valve that shuts off the suction at will. He dilates the pupil with cocain and epinephrin an hour beforehand. This permits the use of eserin, and hernia of the iris is warded off.

Gann, Tokyo

105 *Gastric Tumors in Rabbits Fed with Wool-Fat. Y. Kon.—p. 27.
106 *Hen Sarcoma. T. Ogata and M. Ishibashi.—p. 32.
107 Sarcoma in Mouse Thymus. K. Ichikawa.—p. 34.
108 Fate of Tumor Cells in Blood Stream. M. Takeuchi.—p. 36.
109 *Tumor of Horse Testicle. T. Kimura.—p. 38.

105. **Abnormal Proliferation of Gastric Mucosa after Feeding with Wool-Fat.**—Kon fed rabbits and rats for six months or more with adeps lanae hydrosus, the rabbits taking a daily total of from 5 to 10 gm. with their vegetables. In 50 per cent. nodules developed and adenomatous-proliferation in the pylorus region where the lipoid had accumulated. The range of proliferation was wide, one rabbit presenting an enormous adenoma while another under the same conditions had only a minute lump, but in this rabbit there was a tubular adenoma in the liver with considerable lipoidosis. The tongue, gums and lips also displayed a similar tendency to papillomatous proliferation, and there was also in some a tendency to

deposits of lipoid in the skin and falling of the hair. Two plates accompany the article.

106. **Chicken Sarcoma.**—Ogata and Ishibashi report that they injected subcutaneously in sixty-eight young hens blood serum from hens with one of the three types of sarcoma (the Fujinami, Hayashi and Rous strains). One of the hens injected developed a tumor. It was of the Rous' chondrosarcoma strain. The possibility of thus inducing a secondary tumor seems to be established, thus confirming Busch's similar experience in this line, published in 1914. They warn, however, that as we know of the possibility of blood-borne metastasis, a similar mechanism might explain the secondary tumor growth in this exceptional case. They call attention further to the adsorbing power of kaolin and animal charcoal in respect to tumor virus. When added to a well diluted emulsion of tumor tissue and the whole vigorously shaken up, and then filtered or centrifuged, the filtrate or supernatant fluid never induced tumor growth when injected subcutaneously into hens. On the other hand, the sediment and filter residue proved extremely virulent when injected. By this simple means we have it within our power to materially enrich the tumor-producing substance contained in serum or other fluid mediums.

109. **Testicle Tumors in the Horse.**—Kimura states that veterinarians found 142 tumors of various kinds among 77,224 horses killed in Japan during the last eight years; fifteen in 241,187 cattle, and three in 477,772 hogs. In the horses there were nine cases of tumor in the lung, malignant in all but one; four in the stomach; one in the uterus; forty-nine in the testicles; eight in the kidney; fifty-three instances of melanoma, and fourteen of sarcoma, seat unknown. The various data are tabulated and compared with similar data from European literature. He gives plates showing the microscopic findings in twelve cases of orchidoma or orchidoblastoma in horses—all of the epithelioma type. There were signs of metastasis in six. The horses affected were mostly stallions, 15 years old or over.

Russkiy Vrach, Petrograd

XVI, No. 18-20, pp. 385-408

110 *Acute Edema of the Lungs. N. A. Kruglevsky.—p. 385.
111 *Treatment of Poisoning from Asphyxiating Gases. V. N. Boldireff. —p. 390.
112 *Behavior of the Vegetative Nervous System during Poisoning from Asphyxiating Gases. N. I. Leporsky.—p. 391.
113 *The Nervous Manifestations with Poisoning from Asphyxiating Gases. M. N. Neiding.—p. 397.
114 *The Nervous and Psychic Condition with Poisoning from Asphyxiating Gases. M. Y. Sereisky.—p. 401.
115 *Intravenous Injections of Oxygen in Treatment of Poisoning from Asphyxiating Gases. K. F. Gakh.—p. 403.

110. **Mechanism of Acute Edema of the Lungs from Poisoning with Asphyxiating Gases.**—Kruglevsky analyzes the literature on the subject of acute edema of the lungs, citing in particular the views of Yandell Henderson and Martin Fischer on the mechanism of its origin. The old assumption of capillary pressure, as explaining acute edema of the lungs, failed to take into account the conditions of the natural pulmonary circulation, and hence experimental research in this line was based on inadequate premises. Further light has been thrown on the subject by the sudden poisoning from war drift gases as he explains in detail. Edema of the lungs occurs so rapidly that it reaches its height before inflammation has had a chance to develop.

111. **Treatment of Poisoning from Asphyxiating Gases in War.**—Boldireff urges among other points in treatment that the clothing of the gassed men should all be removed and fresh put on at once, changing even the shoes, as they all hold gas. In moving and in transportation of the gassed men, extreme care is imperative to keep them from jolting and from impure air. Absolute bed rest is imperative, not even allowing them to sit up, for three or five days at least. Talking and smoking should be prohibited, and no smoking should be allowed in their vicinity. As so much of the lungs has been damaged by the gas, the air the men breathe must be uncontaminated. The gassed are peculiarly sensitive to cold, and they must be kept warm and well covered. Fluids must be supplied to the body freely by various means to dilute the over concentrated blood. Revulsion to the chest, dry or wet cupping or mustard pastes are indispensable, especially when there are signs of incipient edema of the lungs. General venesection is not recommended, and there must be no rubbing of the patient to warm him, as this is liable to induce embolism. Among the tonics found useful have been subcutaneous injections of ether, camphor or atropin, and a few drops of anisated solution of ammonia by the mouth. Strophanthin seems the best heart tonic when one is directly indicated, as this drug acts quickly and does not constrict the vessels. In sectors especially exposed to drift gas attacks, ample supplies of extra clothing, gas masks, and everything needed to combat the gases should be kept on hand, not only for the troops but for the civilian population in the gassed region. Last year, he adds, many children were killed by the asphyxiating drift gases. He warns in conclusion that it is often difficult to differentiate poisoning from this source when the circumstances are not known, and he urges close study of the cases for further differential points.

112. **Behavior of the Vegetative Nervous System in the Gassed.**—Leporsky records the reaction to atropin of forty gassed soldiers, and further the reaction to epinephrin and to pilocarpin. The findings with each are tabulated and compared. The responses in the majority indicated vagotony to a greater or less degree. In some cases, however, there seemed to be dissociation; some parts of the vegetative nervous system showed increased and other parts lowered tonus. The asphyxia from the gas poisoning evidently starts the centers in the oblongata to extra functioning, and this in turn deranges the functioning of the glands with internal secretions.

113. **Nervous Manifestations in the Gassed.**—Neiding states that in his 274 cases of poisoning from drift gases there were ninety-six men who showed no symptoms on the part of the nervous system and forty-six with only one, but in 132 there were indications of pronounced involvement of the nervous system, loss or modification of the reflexes and analgesia. Some of the others showed dermographism, irregular and rapid pulse or respiration, or other signs of nervous disorder, as with a traumatic neurosis. Over 50 per cent. of the 274 men thus presented objective nervous manifestations. Some are evidently traceable to direct anatomic injury of nerve tissue from chemicals in the gases.

114. **The Nervous-Psychic Condition in the Gassed.**—Sereisky reviews sixty cases of poisoning from gas attacks, and discusses in particular the nervous and mental condition of seven reaching his service six or eight weeks later. The symptoms indicate, he reiterates, that the gases contain some substance or substances which have a direct toxic action on nerve tissue. Inherited nervous taints render the nerve tissue peculiarly susceptible to the action of this toxic substance.

115. **Oxygen Intravenously in Treatment of Poisoning from Asphyxiating Gases.**—Gakh has only two cases to report in this preliminary communication, but he affirms that the success was striking in both, although as the patients were moribund at the time the benefit was only transient. The symptoms of the gassed show that the organism is perishing for lack of oxygen which the lungs are unable to take up from the air. The experiences with artificial pneumothorax show that a gas can be introduced into the body in large amounts without danger. Gakh's tests seem to demonstrate that oxygen introduced cautiously into a vein is absorbed so rapidly that embolism need not be feared. He injected it with the technic as for artificial pneumothorax, using a morphin needle to introduce the gas into the ulnar vein. All proceeded smoothly in the two cases described, as was anticipated from the theoretical and physiologic premises.

120 Intradural and Extradural Tumor; Two Cases. H. W. Stenvers. —p. 863.

116. **The Separable Minimum in Testing Vision.**—Roelofs describes with a number of plates his research on the smallest space between two dots or lines that can be perceived by the eye. He discusses further how to estimate and record this separable minimum or Auslösungsvermögen, as Hering calls this limit of separate perception.

117. **Peas in Treatment of Deficiency Diseases.**—Holst in Norway found a few years ago that the Norwegian gray pea seemed to be effectual in curing ship beriberi. A trial of these peas (*capucijners*) in the Netherlands West Indies showed that they were effectual also in curing Asiatic beriberi, but Pol states that the action of katjang hidjoe, better known as the *Phaseolus radiatus,* of the bean family, is more powerful. These experiences confirmed the deficiency in vitamins as responsible for the symptoms in both these diseases, although the ship beriberi never develops in the acute form sometimes observed with the Asiatic type. With the former, edema gradually extending upward from the ankles is more common than paralysis, and proper food arrests the trouble at once. The European land type of beriberi usually runs a subacute course, and there is always paresis with or without slight edema. Pol reports in detail a case of this kind in a previously healthy man with three healthy children. He developed ascending paresis which gradually became actual paralysis within five or six months. Even the organ of speech was involved, so that speaking fatigued him; the arms and legs were quite paralyzed. By the sixth month the paralysis was apparently grave until the possibility of the trouble being a deficiency disease was suggested, and the diet was changed to include peas and phaseolus. As the supply of the latter soon gave out, the peas were the main reliance. They were given cooked and also in the form of a decoction, of 2 kg. boiled down to 1 liter, added to his usual food. No benefit was apparent for seventeen days, but then the paralysis began to subside, and in two weeks the paralysis of the legs had disappeared, the improvement continuing to progress in arms, hands and around the mouth in turn, the tongue being the last to return to normal. Fortunately, the long interval before improvement began had not discouraged either physician or patient. When improvement began it was rapid for a while and then subsided into a slow and gradual phase of improvement, corresponding to recuperation of the actually degenerated nerve cells. Traces of paresis were still evident by the eighth month, but there is every reason to suppose that complete recovery will follow in time. The man was a sergeant instructor of the fortress artillery and had to work in water part of the time.

119. **Roentgenotherapy in Gynecology.**—Kouwer warns that roentgenotherapy for fibroma of the uterus is still in the tentative stage. Opinions are still divided as to whether the fibroma itself or the ovaries should be exposed. He warns further that our assumption as to the two separate functions of the ovary—the production of the ovum and of the internal secretion—is still purely hypothetical. But we have reason to assume that roentgen exposures carried far enough are equivalent to castration, and we do not know the damage that may be wrought by the exposures even stopping considerably short of this. Instances have come to his knowlege in which roentgenotherapy has been applied to young women to relieve dysmenorrhea, and even women of 35 and 40 are not excluded from roentgenotherapy by those who fail to appreciate the power of the roentgen rays acting in this region. The gynecologists have not failed to warn of the dangers from operations, and the majority refrain on principle from operating for uterine fibroma unless very serious indications call for it. But, he adds, the roentgenologists are not equally frank in regard to dangers from roentgenotherapy. The medical literature in the Netherlands has no reports of injury of patients from roentgen treatment. He knows that such cases exist, but where are the reports of them? In referring to the Freiburg method of abrupt and very powerful application of the rays, he says that it is not difficult to learn from the very reports of their 1,395 cases sent out by the Freiburg clinic the harm done in this or that case. "How does it happen," he exclaims, "that Freiburg is deaf and blind to them? How can it be explained that, nevertheless, the statements of König and Gauss are accepted by many as absolute authority?"

126 The Habitual Posture in Schoolchildren. P. Haglund.—p. 897.

122. **Carrel Treatment of the Suppurating Processes of Peace.**—Gramen applied the Carrel method first in a case in which the leg had been run over by a freight car. While waiting for the shock to subside to permit amputation, a trace of warmth was detected in the foot and conservative measures were applied, but in the course of six weeks the ulceration and necrosis had become so extensive that amputation seemed finally inevitable. The leg was then treated by the Carrel method, and in two days there was marked improvement and the lesions began to heal rapidly. The man is now walking with crutches, the leg 30 cm. shorter than its mate. In other cases of extensive suppurating processes, healing was more rapid and complete than under the ordinary measures. The method has been applied in several hundred cases at the Stockholm Hospital, and the general impression was equally favorable, but occasionally cases were encountered which did no better with this than with other methods. In thirteen cases of appendicitis, cholecystitis or salpingitis, a combination of the Carrel technic with the Mikulicz tampon gave excellent results, placing the Carrel drains inside the sack and tamponing around them. Warming the Dakin fluid to 37 C. seemed to reduce its strength about 0.007 per cent. per day. Patients with burns of the third degree complained of pain from the fluid. In one case of total streptococcus empyema, requiring rib resection, the collapsed lung showed no tendency to expand, but after secondary suture under Carrel treatment, healing proceeded by primary intention and the pneumothorax was gradually absorbed.

124. **Thrombosis and Embolism in Mesenteric Vessels.**—Hedlund has compiled about 373 cases of thrombosis and embolism of the mesenteric vessels, and reports two additional cases from his own experience, both fatal, in women of 40 and 59. The cases on record were nearly all in persons over 36; all but 38 per cent. were in men. In 6 per cent. both arteries and veins were involved; in 50 per cent. the arteries alone. Endocarditis and endarteritis are the usual causes, and some recent serious sickness, such as pneumonia, is common in the antecedents. The clinical picture may set in with bloody diarrhea or symptoms of ileus, with remittent attacks of pain, vomiting, sweats, violent localized peristalsis or paralytic ileus; collapse soon follows, with gangrene of the bowel and peritonitis. In one of his two personal cases there was gangrene from anemia, in the other hemorrhagic infarction, but the clinical picture in both was that of ileus. The course may be briefly fatal or it may drag along for months, the colic-like pain returning about thirty or sixty minutes after a meal, and lasting for from two to four hours, without localized peristalsis or stiffening of the bowel. In one of Hedlund's cases the trouble began with a chronic course, not flaring up into the acute phase until after about nine months.

THE CAUSATION AND CURABILITY OF CERTAIN LONG-STANDING ALBUMINURIAS *

DAVID RIESMAN, M.D.

PHILADELPHIA

During the past few years a number of cases of albuminuria have come to my notice in which investigation showed the existence of a local focus, the removal of which led to the disappearance of the albuminuria. Thanks to the work of Billings and his school, we know the importance of foci of infection in the production of systemic disease. It is of interest to note that as early as 1802 Benjamin Rush pointed out in a letter the relation between systemic disease and caries and abscess of the teeth.

That severe local infections, such as ulcerative endocarditis, tonsillitis, and, indeed, most other acute infections, are capable of producing nephritis of the parenchymatous type, is of course a long-established fact. With this form of nephritis, which is an immediate result of the acute toxemia, I am not dealing. The type to which I desire to call attention is entirely devoid of acute features, and has all the earmarks of chronic renal disease. We know how futile is the attempt in the majority of such cases to remove the albumin from the urine by means of drugs or by diet.

These insidious albuminurias are often found in apparently healthy men who, in full confidence, apply for life insurance, only to be refused temporarily or permanently, because of the trace of albumin in the urine. Among adolescent subjects some cases have been classed as cyclic, orthostatic or postural albuminuria, a condition that as yet has no very satisfactory explanation. These cases are rather easily recognized. They give, as Barker and Smith[1] have shown, normal phenolsulphonephthalein outputs, and in other ways behave as cases of a nonprogressive type of renal irritation. Apparently the worst that can be said of them is that they bar the patient from life insurance.

While many cases of albuminuria of slight degree and springing from no obvious cause are due to early interstitial nephritis, there are some in which a careful search reveals a disease focus that stands in etiologic relation to the albuminuria. Let me illustrate this by a few examples:

CASE 1.—J. J. H., a boy, aged 9 years, came under my care because of poor and capricious appetite and general lack of vitality. He had been a difficult "feeding case" as an infant, but had not had any special diseases. From birth he was sensitive to protein, particularly egg protein, which caused hives, as his mother said, "almost before he swallowed it." Once he passed a little gravel. The tonsils and the cervical glands were enlarged, but the boy was not a mouth breather. There was also some enlargement of the spleen. The urine was very scanty, and for a year or more had contained a small amount of albumin and occasionally hyaline and granular casts. There was no edema. All manner of treatment was tried without producing any marked changes in the urine either in quantity or in quality.

Although the boy had never had a genuine attack of tonsillitis, I thought it best to have the tonsils removed, since they looked unhealthy. They were extirpated under ether, April 1, 1913, nearly two years after the discovery of the albuminuria. Both tonsils were found to contain cheesy masses, and in one there was an abscess. There was also a large adenoid. The second specimen of urine examined after the operation was free from albumin. Then, for a little while traces reappeared; but at the end of about six months both albumin and casts had entirely vanished. The appetite at present leaves nothing to be desired, and the lad is one of the finest and most agile of his age.

CASE 2.—A man, aged 42, a veterinary surgeon, came under my observation in 1913, stating that for years he had had pain in the right lower abdomen, which had sometimes been looked on as appendicitis, sometimes as renal colic. He had never passed blood or gravel, and only once—for about a week in 1911—he had passed pus. He had become more or less reconciled to the diagnosis, made by many medical examiners, of Bright's disease. The urine showed, when I examined it, just as it had done for many years, a small amount of albumin. Jan. 20, 1913, after the confirmative evidence of a roentgen-ray examination, a successful operation for the removal of a stone was performed by Dr. B. A. Thomas. The albumin disappeared quite promptly. When I last saw the patient, he seemed to be entirely well.

CASE 3.—A man, aged 21, a college student, was sent to me by Dr. W. P. Walker of South Bethlehem, because of albuminuria, which had been discovered during an examination for life insurance. Since 1909 the boy had had four sharp attacks of tonsillitis, notwithstanding the fact that he had had an operation for adenoids and enlarged tonsils in 1907. He had passed through measles, chickenpox and whooping cough in early life. The urine had a specific gravity of from 1.016 to 1.024, and contained albumin and sparse hyaline casts and occasional red blood cells. His blood pressure was 120 systolic and 80 diastolic; the weight was 109 pounds. The phenolsulphonephthalein test showed 53 per cent. in the first two hours and 15 per cent. in the third hour. The onset of elimination was somewhat delayed, requiring twenty minutes. The quantity of urine was about normal. While at Yale he was seen by Dr. Tileston, and on one occasion by Dr. Pratt of Boston. Both found the condition that I have described.

In June, 1914, the young man, with a number of other students, fell ill with sore throat, after eating in a certain restaurant. Feeling better at the end of twenty-four hours, he went to his home in Bethlehem, where he immediately had a relapse. The throat was intensely inflamed, and on the swollen tonsils there were discovered follicular spots, as well as areas of whitish exudate. The patient was extremely weak and prostrated, and had great difficulty in swallowing.

---

* Read at the meeting of the Association of American Physicians, Atlantic City, May 3, 1917.

[1] Barker and Smith: Am. Jour. Med. Sc., 1916, 151, 44.

I saw him with Dr. Butler, and felt sure that he had streptococcic sore throat. After his recovery, which ensued without serious interruption, the tonsils, from which he had suffered so much during the preceding four or five years, were thoroughly extirpated. The albumin disappeared from the urine thereafter, and the last account I had from the young man was that he was perfectly well.

When, on one occasion, I discussed the subject of albuminuria due to focal conditions with Dr. B. A. Thomas, he told me that he could supply me with the histories of several striking cases. He has been kind enough to do so, and I copy one:

Case 4.—A man, aged 22, consulted Dr. J. C. Birdsall, Dr. Thomas' assistant, Feb. 15, 1915, because of albuminuria discovered, Jan. 1, 1914, during examination for life insurance. The urine showed a light cloud of albumin but no tube casts. Examination of the pharynx revealed diseased tonsils. A tonsillectomy was advised, which was done during the summer of 1915. October 9, the urine still showed a cloud of albumin. December 17, the patient suffered an attack of bronchitis. Sputum culture revealed the pneumococcus and the *Staphylococcus albus*. An autogenous bacterin was prepared, of which the patient received a number of injections. The urine was examined several times during the next two months, and on every occasion was found free of albumin.

Dr. Thomas also tells me that he has seen a number of instances of chronic albuminuria in syphilitic patients in whom the albuminuria entirely disappeared after antisyphilitic treatment.

The point that I desire to bring out is that cases of long-standing but otherwise mild albuminuria should not be looked on as incurable, unless evidence on the part of the cardiovascular system, or testimony given by functional tests, clearly demonstrates that the kidneys are diseased. This applies also to the so-called orthostatic or postural albuminurias of adolescents. The albuminuria may be kept up by disease of the tonsils (which is not always discoverable by simple inspection), by dental abscesses, by other infective foci, or by the presence of a stone. It may be made to disappear entirely, at least in some cases, by the removal of the offending focus. This gratifying result does not always set in immediately, but sometimes only after a number of months. The physician, therefore, should not be too soon discouraged. It is probable that kidneys which have been for a long time the seat of slight irritation will always be somewhat sensitive, whence it follows that patients cured of albuminuria should remain under medical observation for a number of years.

1715 Spruce Street.

Automobile Accidents in New York.—In a statement issued by State Commissioner of Health Herman M. Biggs an interesting and significant comparison is made between the number of deaths in the state caused by automobile accidents and typhoid fever, as well as other causes of death. While typhoid fever mortality was reduced 26 per cent. in 1917, the deaths from automobile accidents increased so much as to take the place of typhoid fever as one of the principal preventable causes of death. In September, 1917, there were 155 deaths from automobile accidents, more than the combined mortality from homicide and suicide, and undoubtedly a much greater number of injuries involving prolonged illness and more or less permanent disability. Of these deaths 55 were in New York City, 63 in upstate cities and 37 in rural districts. Typhoid fever caused 84 deaths among 796 patients during September. For the year 1917, up to September 30 there were 755 deaths from automobile accidents, while for typhoid fever there were 434 deaths among 2,840 patients.—*Bulletin* New York State Department of Health.

THE USE OF BISMUTH IODOFORM PASTE IN OUTPATIENT WORK *

VINCENT O'CONOR, M.D.
and
HENRY A. KREUTZMANN, M.D.
BOSTON

The treatment of postoperative hospital cases, as well as that of minor surgical conditions, comprises the general function of the routine work in the outpatient departments of our larger hospitals.

The chronically obstinate sinuses of osteomyelitis, tuberculosis, fecal fistula, empyema, lung abscess cavities and innumerable similar conditions present problems of no small importance to the outpatient surgeon who must receive the convalescent patient on his discharge from the hospital ward and take over the problem of promoting a rapid and complete recovery.

Another difficulty with which the outpatient surgeon has to deal is the indifference and the neglect of the patient to return regularly for treatment.

It was the hope of obtaining better results than with the means commonly employed that led us to use bismuth iodoform paste, first described and used by Rutherford Morison[1] in the treatment of war wounds at the Northumberland War Hospital, England.

In our work we have used two preparations of bismuth iodoform paste, the original paste and an emulsion.

The paste is prepared according to the formula of Morison. It is composed of bismuth subcarbonate or subnitrate, 1 part, iodoform, 2 parts, and liquid petrolatum, 1 part. We devised the emulsion because of the difficulty of introducing the paste into deeper cavities which necessitated drainage through a narrow sinus. This emulsion, which we have called "liquid bipp" (bismuth iodoform petrolatum paste), is composed of bismuth subcarbonate, 1 part, iodoform, 2 parts, and liquid petrolatum, 4 parts. Both preparations are easily and cheaply prepared.

Our treatment of highly infected wounds has been identical with that described in the British war hospital. The wound is first thoroughly irrigated with sterile saline, or 1:25 boric acid solution. It is then liberally swabbed out with 75 per cent. alcohol. The surrounding skin is shaved and cleansed in the same manner. The wound with all its cavities and pockets is tightly packed with bismuth iodoform paste and closed with the usual silkworm-gut or silk sutures.

The type of cases in which the foregoing has been employed has included only those in which we had previously allowed the wounds to heal by second intention or had drained them with rubber tissue. In the case of the majority of the patients treated with bismuth iodoform paste, the wound healed by first intention, with no resultant sinus, leaving a clear-cut insignificant scar. In highly infected cases, healing was effected by rapid granulation from the bottom.

In two patients with tuberculous cervical adenitis in which suppurating glands were removed from tissue that was thoroughly necrotic, curettage, swabbing with alcohol, and packing with bismuth iodoform paste were followed by complete closure. There was healing by first intention and recovery without sinus formation. We report this because in similar cases it had previously been our custom to employ drainage. The resultant sinus healed by second intention only after many days, and was complicated by excessive granulations.

---

* From the Surgical Outpatient Department, Peter Bent Brigham Hospital.

[1] Morison, Rutherford: Lancet, London, 1916, 2, 268-272.

As to the relative value of bismuth iodoform paste and Beck's paste in the treatment of osteomyelitic sinuses, it is as yet too early to make an accurate or fair comparison. We have convinced ourselves, however, that the injection of the liquid bismuth iodoform mixture, accompanied by the maintenance of proper drainage, has thus far been more satisfactory than any of the older methods of treatment.

The results obtained in the postoperative treatment of a large number of empyema and lung abscess cavities have been extremely encouraging.

In these cases the sinus is completely filled with the liquid bismuth iodoform mixture by instillation with a large glass syringe through the rubber drainage tube. In this way the cavity and sinus are both completely filled with the emulsion, and the drainage tube remains in situ. It is not necessary for the patient to present himself for another dressing for from three to five days.

We have succeeded in obtaining a complete healing in four chronic cases which had obstinately resisted all other methods of treatment during a long period of time. More than half of the recently operated on patients that were given this treatment have progressed at a more rapid and satisfactory rate than prevailed under older methods of treatment.

A decided advantage of this paste is its nontoxicity even when it is used in large quantities. The possible dangers arising from the use of large amounts of iodoform and bismuth are iodoform poisoning and poisoning from lead which may be present in impure bismuth carbonate or subnitrate. Morison[2] asserts that in his entire series he has had only two patients in whom symptoms of poisoning by either of these drugs were severe enough to demand removal of the paste from the wound.

To prevent the introduction of lead into the wound, each batch of the bismuth salt is first tested for the presence of lead before it is incorporated into the paste.

Hepworth[3] reports five cases of poisoning occurring in the Wharncliffe War Hospital, Sheffield, in which symptoms suggesting plumbism were present. He describes a simple and yet delicate test for the presence of lead which we have used in our work with the greatest satisfaction.

We have been constantly on the watch for any symptoms of poisoning. Thus far we have had only one patient, with a large empyema cavity, in whom there was a blue line localized on the gums about the two canine and the two incisor teeth of the lower jaw. A piece of the bluish red gum was excised and studied microscopically and chemically. Chemical tests for both bismuth and lead were negative. Microscopically, the pigment was found in the layers of the rete. A definite decision as to whether the substance was lead or bismuth sulphite was not made. Since the patient had absolutely no untoward symptoms, the treatment was continued, careful observation being made at each visit. The red blood cells have shown no change, and the urine has not contained bismuth. The empyema cavity is healing rapidly from the bottom.

CONCLUSIONS

The advantages of bismuth iodoform paste lie in its marked germicidal action and stimulation of rapid tissue growth.

It is cheaply and easily prepared, is nontoxic, and requires no great skill in application.

An added feature in outpatient work is that less frequent dressings are necessary and therefore require a decreased number of visits per patient. This is often an economic saving of no small importance to the laboring patient.

The object of this article is to draw the attention of other outpatient departments to this preparation as a valuable addition in the treatment of similar cases in civil practice.

OPERATIVE RISK IN CARDIAC DISEASE *

JOHN M. BLACKFORD, M.D.
SEATTLE
FRED A. WILLIUS, M.D.
AND
S. B. HAINES, A.B.
ROCHESTER, MINN.

General impressions of operative risk in cardiac disease are scattered throughout medical literature, but we have been unable to find any summary of results in a given series of cases. The failure to report such results must be due largely to two reasons: first, the difficulty of accurately classifying cardiopaths into similar groups, and second, the fact that in ordinary work few observers have an opportunity to study any series of such patients needing surgical treatment. These reasons are sufficient to make us feel some temerity in reporting a series of such cases, and yet we feel that such a report may throw some light on the subject.

Experience here has taught us that the best measure of operative risk in cardiac disease is a good clinical impression of the patient's ability to stand physical strain, in addition, of course, to a good history and a physical examination. Cases in which the heart permits the patient to go about, or in which it can be sufficiently restored by treatment to allow this, usually have been considered safe for operation. The "goiter heart," the "fibroid heart," the "prostate heart," etc., are often so remarkably improved following operation as fully to justify the risk. Cardiac disease due to focal infection, particularly tonsillitis and rheumatism, often shows the same happy result following the removal of the focus. A malignant condition complicating heart disease is considered operable if a fair hope of cure is offered, and palliative operations are often indicated in such cases. In very few instances in which there has been urgent need of operation has it been refused on account of the cardiac condition, though in many, the operation has been undertaken only after preliminary medical treatment. The decision in each case is based on several factors: (1) the immediate operative risk; (2) the probable improvement of the condition of the heart following the operation; (3) the patient's relative chance for length of life or general health with and without the operation, and (4) in less serious conditions whether the operative relief will justify the increased risk.

* From the Mayo Clinic.

Our experience in general has justified the taking of risks in cases demanding surgical intervention.

A rational classification of cardiac risks on a basis of valvular disease alone is impossible. Valvular disease, with myocardial compensation sufficient to allow marked exertion, does not increase operative risk. With reasonably good compensation, allowing moderate exertion with comfort, the risk is not greatly increased, that is, a mitral stenosis may be slight and not increase the risk. With moderately good compensation the risk is not great, whereas with a very badly damaged myocardium it may be greatly increased. Similarly an aortic lesion without cardiac symptoms is easily operable, whereas the heart would not be considered operable if there was marked angina associated with the lesion. Manifestly the presence of valvular disease alone gives a poor basis for grouping similar cases.

A classification based on attempts to measure the cardiac reserve is also impossible since we have no accurate means of measuring it, and clinical impressions are variable. Angina pectoris, aortic valvular disease with pain, and aortitis with dilated aorta are universally recognized as marked contraindications to operative interference; but the risk in such cases is variable, and so few patients have been operated on that a correct statement of the risk is impossible.

Recent advances in cardiac study, particularly of the electrocardiograph, have given opportunity for better classification. We have studied results in four groups of cases of disordered cardiac mechanism that are universally recognized as bad risks—the worst groups of risks, if we except angina pectoris and allied conditions. These groups are: (1) auricular fibrillation; (2) auricular flutter; (3) impaired auriculoventricular conduction, and (4) impaired intraventricular conduction. No clinician will take exception to the statement that these disorders include the worst of cardiac risks; they give definite objective findings and are accompanied usually by extensive myocardial damage. A history showing any such cardiac disorder should always be very carefully considered.

We did not have an opportunity to examine before operation all the patients having cardiac trouble, and therefore selected only those who had had electrocardiograms taken since August, 1914. These represent the larger number of surgical cases in which cardiac disease was a complication. Undoubtedly a few patients were so obviously in a bad condition that the clinician did not consider a complete examination necessary (that is, an electrocardiogram) and sent them home. If moribund patients and those bedridden by heart disease are excepted, our summary is a fair average of patients in whom cardiac operative risk is necessarily gravely considered. As we have mentioned, angina pectoris has not been included in the series because no evident grounds for grouping similar cases are apparent, and patients suffering severely from the condition are rarely considered operable.

AURICULAR FIBRILLATION

The mechanism of this disorder is now known to be rapid incoordinate contractions of individual muscle-bundles of the auricular wall, that is, fibrillary twitchings, descriptively called "fibrillation." The auricle loses its pumping function and becomes a dilated organ, acting only as a reservoir in the circulation. The condition is characterized in the larger number of cases by a totally arrhythmic pulse and often by a marked tachycardia. Usually fibrillation is a permanent cardiac disorder, though in a definite percentage of cases it is paroxysmal, with an established sinus rhythm between attacks.

Exophthalmic Goiter.—Extensive experience with hyperplastic toxic (exophthalmic) goiter makes it evident that fibrillation is an end-result of the disease toxin on the myocardium. The fibrillation is found in young patients when the toxemia is severe and has continued a long time. It is usually much less frequent under than above the age of 40.

We have recorded nine patients under 30 years of age, the youngest 21, and twelve between 30 and 40 years of age, a total of twenty-one patients under 40 years. This group comprises the worst risks. Usually the myocardiums of young patients stand the strain well; yet they have given out, and this is evidence of extreme toxemia and stress. A high mortality should be expected. One patient died following a Porter hot water injection; three died in from four to six weeks at home (reported as one cardiac death, two due to pneumonia); two died eight and fifteen months following thyroidectomy; that is, six of twenty-one patients died within fifteen months. We have recently heard from eleven of the fifteen remaining patients. Five report that they are almost or completely well, and six report definite to marked improvement. To recapitulate: Of twenty-one patients under 40 years of age with fibrillation due to exophthalmic goiter, one third are well, one third are improved definitely to markedly, and one third are dead.

In older patients (more than 40 years old) it is expected that the myocardium will break down more easily, and that it will show poorer recuperative power. We have recorded forty-nine patients more than 40 years of age with fibrillation, and have recently heard from twenty-one of them. Three are dead, one being an operative mortality, one dying six years after thyroidectomy and fifteen months after a radical operation on the breast for carcinoma (fibrillation clinically eleven years), and one dying in nine months from "heart failure." Eighteen of the series report as follows: Thirteen are much or completely relieved of cardiac symptoms, four are definitely improved though still cardiopaths, and one reports questionable improvement.

The gross operative mortality of seventy cases of fibrillation associated with exophthalmic goiter is two deaths, or 2.8 per cent., which compares very favorably with the present normal operative mortality of 2.6 per cent.

Thyrotoxic Adenomas.—This group represents the typical *Kropfherz* of Kocher, the "goiter heart." Clinical observation has long shown that certain patients with "simple goiter" after years of good health gradually develop thyrotoxic symptoms and cardiac disease. A considerable percentage of such patients later show auricular fibrillation; in seventeen cases of fibrillation there was one operative death, and two deaths in nine and twenty-three months, respectively. Seven other patients have been heard from; four are almost or completely well, two are definitely improved, and one is questionably improved.

Work on basal metabolism has shown that these patients have a constantly high metabolic rate, comparable to that of typical exophthalmic goiter. This, with the similar myocardial damage and the remarkable cardiac improvement in most cases after operation, makes the operative risk well worth while, and much smaller than is generally believed.

Other Diseases.—There were nine cases of fibrillation in patients less than 40 years of age and sixteen more than 40, making a total of twenty-five. The operations have been as follows: nine tonsillectomies, four excisions of epitheliomas (two lower lip, one gland of the neck, one larynx), one excision of a gland of the neck for diagnosis (sarcoma), three cholecystectomies and appendectomies, three gastro-enterostomies, two for ulcer, one for carcinomatous obstruction, one Talma-Morrison, one herniotomy, one cataract extraction, one suprapubic stab, and one cauterization of urethral caruncle. There were two early fatalities, one a postoperative death due to decompensation in the case of suprapubic stab, and one from cholangeitis following a gallbladder operation. One patient died a cardiac death nine months after tonsillectomy. Three others are dead, one death being reported as due to paralysis, one as due to peritonitis, and one as due to sarcoma. This makes six deaths in the twenty-five cases, only two of which were due to the cardiac condition. In recent reports from eleven patients, all but one say they are definitely to markedly improved as regards the cardiac complaint. The patients who had tonsillectomies seem to have done particularly well.

AURICULAR FLUTTER

This disordered cardiac mechanism is recognized as due to the rapid coordinate contractions of the auricles, stimulated by foci of irritation located in the auricular wall outside the normal pacemaker. The auricles contract at a rate of 200 to 380 and the ventricles usually at one half the auricular rate, though any rhythm from a 1:1 association to complete heart block may exist. The pulse is regular in one half of the reported cases and grossly irregular in the other half. The degree of block may vary from time to time, and most patients are subject to paroxysmal "weak spells," owing to a sudden decrease in the degree of block allowing the ventricles to assume the full auricular rate. The condition is usually chronic, and may exist for years. A "weak spell" during the operation is an evident danger, though we have not observed it. Four patients have been operated on, all included in the foregoing under fibrillation. These patients are of particular interest as apparently being the first proved cases of flutter in which an operation has been done.

We have reported elsewhere[1] that these four patients were subjected to vigorous digitalis and rest treatment until fibrillation was brought on and then the operation was done. Three of the patients had exophthalmic goiter, though one had a cholecystectomy and tonsillectomy in the clinic, and a thyroidectomy elsewhere later. One other patient had had a tonsillectomy. All the patients with exophthalmic goiter resumed a normal rhythm after the operation, and two had no cardiac symptoms. The last patient (tonsillectomy) reports himself greatly improved. Thus far, there has been no mortality.

PARTIAL OR COMPLETE HEART BLOCK

One patient with complete block has had three operations in eleven years—appendicectomy, amputation of breast for carcinoma, and excision of recurring skin nodules. The cardiogram was taken before the last operation, but the pulse was remarkably slow at the former examinations. The patient is alive and reasonably well. Six patients showing delayed conduction-time between auricles and ventricles, that is, auriculoventricular intervals of from 0.22 to 0.28 second, have been operated on as follows: three for diseased tonsils, one for exophthalmic goiter, one for thyrotoxic adenoma, and one for gallbladder disease. Thus far, we have no knowledge of a death in these cases. Four of the patients recently reported that they are markedly improved or cured.

INTRAVENTRICULAR BLOCK

This disorder is due to impaired conduction of the cardiac impulse after it has passed the bifurcation of the auriculoventricular bundle. It is evidence of disease in the main branches of the bundle or in the subendocardial plexus, causing a slow and ununiform diffusion of the contraction stimulus throughout the ventricular wall. Recently Oppenheimer and Rothschild[2] have excellently presented this subject and have called attention to the serious cardiac damage and the early fatality which it usually indicates. As a basis for clinical interpretation we have used for several years the same criteria which they present, and we are able to confirm their general findings in a larger series of cases (158).

The electrocardiographic curve in this condition shows a prolonged QRS complex (active ventricular phase), and variations of this up to the remarkable complexes which have been described as branch bundle defects. Undoubtedly such curves indicate extremely bad myocardial damage, as may be readily determined by ordinary clinical methods.

Relief of a probable infectious or toxic focus for the cardiac disease has seemed advisable, and operations have been done with this in view. Twelve patients have been operated on: seven tonsillectomies, four thyroidectomies (three exophthalmic goiter and one thyrotoxic adenoma), one ligation for exophthalmic goiter, and one salpingectomy. Six of the seven tonsillectomy cases had histories of rheumatic fever. One patient died of cardiac insufficiency one year after tonsillectomy; seven others (five with definite valvular disease) report definite to marked improvement in general health. It would seem, therefore, in such cases that if a surgical condition appears as a cause or aggravation of the cardiac disease, operation should be undertaken, particularly if goiter or tonsillitis is the disturbing condition. Five of our patients were 30 years of age and two were younger, and improvement is greatly desired for such young patients.

SUMMARY

We do not believe that valvular disease with good or reasonably good compensation should be considered as a contraindication to operation, because the surgical risk is not materially increased in such cases. Careful anesthesia is, of course, essential. In the Mayo Clinic, the record of 120,000 ether anesthesias with but one death under anesthesia is evidence of the remarkable safety of ether when properly administered.

The best idea of the cardiac risk in surgical cases is derived from a carefully balanced impression of the patient's general ability to stand stress. If the patient is ambulatory without marked decompensation, operation is usually safe. If marked cardiac insufficiency is evident, the patient should be medically treated until a fair degree of compensation is restored.

[2] Oppenheimer, B. S., and Rothschild, M. A.: Electrocardiographic Changes Associated with Myocardial Involvement, The Journal A. M. A., Aug. 11, 1917, pp. 429-431.

Surgical intervention should not be undertaken in a cardiopath unless there is definite reason to believe that the surgical relief is essential to reasonable health or will improve the cardiac condition. "Meddlesome surgery" has a fuller meaning in treating cardiopaths.

Extremely severe cardiac disease can often be definitely to completely relieved by the removal of an infectious, mechanical or toxic source of cardiac strain or degeneration. In cardiopaths suffering from goiter the relief is often beyond all expectations. Not infrequently in such cases patients are transformed from confirmed invalids to active, useful persons.

Of one hundred patients operated on with auricular fibrillation, there was a gross surgical mortality of 5 per cent.; but in only 3 per cent. death was due to cardiac disease. That is to say, 3 per cent. represents the increased risk in one hundred patients. Thirteen per cent. have died since leaving the clinic. Forty-seven others report as follows: Eight are subjectively well, twenty are markedly improved and able to lead fairly active lives, sixteen are definitely improved but still obliged to avoid exertion, and three report little or no improvement.

Four patients with auricular flutter were operated on after fibrillation was brought on by treatment. Two are subjectively well, and two are markedly improved.

Seven patients with partial or complete heart block (six partial, one complete) were operated on, with no deaths. Three of the patients are markedly relieved, and one is unaware of cardiac difficulty at present. The complete block is unchanged.

Twelve patients with intraventricular block were operated on, with the result that one died a year following tonsillectomy, and seven report definite to marked improvement, in spite of evident valvular disease.

We wish to emphasize the fact that these results are given with the belief that they represent what are usually considered the worst surgical cardiopathic risks (except angina and allied conditions). With few exceptions they include all cases of bad cardiac disease in the clinic that needed surgical treatment.

Myocardial insufficiency finally reaches a point at which there is no possibility of improvement with any method of treatment with which we are familiar. We know only of the therapeutic test to determine this point in doubtful cases, and the foregoing results show that until such a stage of decompensation is reached the patient should at least be given the chance of surgery. The improvement following surgical interference in suitable cases has been so remarkable as fully to justify accepting the somewhat increased risk. The general tendency unquestionably is to overestimate the danger of operative fatality. In cases in which surgery can relieve, cardiopaths should not be refused operation, at least until a therapeutic trial has been given for the reestablishment of some compensation.

Patients with arrhythmia, particularly fibrillation, stand operation remarkably well after medical treatment. It may be said that the fibrillating auricle has whipped the ventricle until continued ventricular action proves a reasonably good ventricular power, and life depends on ventricular, not auricular, action. Our ability to estimate operative risk depends on our ability to estimate the ventricular reserve, and remarkably little reserve seems necessary to carry the patient through good ether anesthesia. That we may err in judgment is evidenced by our three cardiac surgical deaths, and eight other deaths within a year from cardiac insufficiency. However, the general results of definite to marked improvement in about 80 per cent. of suitable cases is ample justification for accepting the increased mortality.

From the foregoing study we seem justified in making the following definite conclusions: first, that many properly selected cardiopaths, often considered hopeless, may be relieved by surgical measures, and second, that the general tendency at present is to require too great a margin of cardiac safety in surgical work.

THE BRUCK PRECIPITATION TEST FOR SYPHILIS

ARTHUR WILLIAM STILLIANS, M.D.
Attending Dermatologist, Cook County Hospital; Consulting Dermatologist, Chicago Lying-In Hospital
CHICAGO

Since the adoption of the complicated complement fixation test for syphilis, repeated attempts have been made to simplify it or to substitute for it a simple chemical test. Most of these substitute tests have been precipitation tests, and so far all have failed to attain any practical degree of diagnostic accuracy. Bruck,[1] the collaborator of Wassermann on the complement fixation test, has recently brought out another, for which he claims specificity. Since the war began he has continued his research under the restricted facilities of a field hospital, and found that the nitric acid precipitate in syphilitic serum dissolved more slowly on neutralization with alkalis, than the precipitate in normal serum. He then sought the quantity of distilled water necessary to dissolve the normal precipitate without dissolving that in syphilitic serum. The test thus evolved has given good results in his hands, and he suggests that it be tried out by other experienced laboratory workers in the hope that it may be of use in diagnosis or at least may shed further light on the character of syphilitic serum. He suggests that it may be of especial value to the military surgeon unable to obtain the help of the Wassermann reaction, in determining whether or not it is necessary to send certain patients back from the front for antisyphilitic treatment. In view of the needs of the approaching time of demobilization of the troops, he suggests that any additional aid to the diagnosis of syphilis will be welcome.

As a reagent he uses the acidum nitricum purum of the German pharmacopeia, which is about 25 per cent. nitric acid with a specific gravity of 1.149. Five-tenths c.c. of clear serum is put into a large test tube, 2 c.c. of distilled water added, and the tube shaken. Then, the exact time being noted, exactly 0.3 c.c. of the reagent is added, the tube again shaken, and allowed to stand ten minutes at room temperature. To the white precipitate thus formed, 16 c.c. of distilled water are then added, and the tube, capped by the finger, is carefully inverted three times, the formation of froth being avoided. Again the tube is allowed to stand ten minutes and then inverted three times in the same way, froth formation always being avoided.

---

[1] Bruck, C.: Eine sero-chemische Reaktion bei Syphilis, München. med. Wchnschr., 1917, 64, 25.

After the tube has stood for half an hour at room temperature, the reaction may be read. All tubes showing more than slight opalescence are read as positive, all tubes with clear contents as negative. The author suggests that the reading is easier if the tubes are allowed to stand twelve hours, when the precipitate will be seen at the bottom. The tubes then showing only a slight precipitate, *kleine kuppe*, are to be read as doubtful or negative. The necessity of accuracy in measurement of the reagent, and in timing the various parts of the reaction is emphasized.

In about 200 syphilitic serums there was practically complete agreement with the Wassermann reaction. Only three Wassermann positive serums, from one latent and two secondary cases, gave negative Bruck reactions. On the other hand, one case of congenital syphilis and one tertiary case gave positive Bruck reactions, although the Wassermann test was negative. Of about 200 nonsyphilitics, all were negative except four cases of old infected wounds of knee and thigh, long febrile, and one febrile case of tuberculosis. A positive test in a febrile case, therefore, is not trustworthy.

Bruck does not put forward his test as a substitute for the Wassermann reaction, but thinks that it may possibly be due to the same peculiarity of syphilitic serum responsible for the Wassermann reaction, and that it may be useful in connection with the latter. If it proves a practical aid to diagnosis, it has the great advantages of requiring only a simple laboratory outfit, a single stable reagent, and little time.

I have performed the new test under the conditions prescribed by the author in 209 cases. In fifty-three of these, more than 25 per cent., the results disagreed with those of the Wassermann reaction. In thirteen cases of active early syphilis, in all of which the Wassermann reaction was very strongly positive, the new test was negative. On the other hand, 24 per cent. of seventy-four nonsyphilitics gave positive Bruck reactions. These occurred in one febrile case of septicemia and in sixteen afebrile cases, one of gonorrheal urethritis, one of gonorrheal arthritis, one of xanthoma planum et tuberosum, one of systemic blastomycosis, one of dermatitis venenata, and in one healthy man, three nursing women and eight pregnant women, apparently healthy.

COMPARATIVE RESULTS OF TESTS

Diagnosis	No. of Cases	Positive Wassermann Reactions Per Cent.	Positive Bruck Reactions Per Cent.
Early active syphilis	31	100	58
Late active syphilis	12	92	58
Latent syphilis	54	67	20
Nonsyphilitic	74	0	24

Bruck states that either active or inactivated serum may be used for the test. In 115 cases in which I have performed the reaction with both active and inactivated serum, the result was the same in ninety-eight cases, but differed in seventeen. In fourteen cases the active serum gave a positive reaction, the inactivated a negative, while in three cases the reverse occurred. That these differences were not all accidental, from slight differences in technic such as Smith and Solomon[2] have shown to be important, was indicated by the fact that repetition of these tests in many instances gave exactly the same result. The only departure from the original technic as published by Bruck was that the tubes were allowed to stand over night, from eighteen to twenty hours, before being read. Attempts to read them within a few hours were discontinued as valueless, for it was impossible to say which tubes would give a precipitate and which would not. The author of the test himself advises that they be allowed to stand twelve hours before being read. In every other respect the technic as given by Bruck has been carefully followed.

Since this paper was begun, Smith and Solomon[2] have reported their results in a series of 400 cases. They insist on several refinements of technic omitted by the originator of the test; but in spite of their use of these, their results disagreed with those of the Wassermann reaction in 25 per cent. of the cases, and in 302 nonsyphilitics they had 28 per cent. of doubtful or positive reactions. In syphilis of the central nervous system their Bruck reaction differed from the Wassermann in only ten of sixty-nine cases, or 14 per cent. In twenty-two other syphilitics the two reactions differed five times, or 23 per cent. These are better results than I obtained in my series of ninety-seven syphilitics in all stages, for I had 35 per cent. disagreements with the Wassermann reaction, in nearly all of which the Wassermann was correct. On our whole series we agree in having had disagreement between the two reactions in 25 per cent. of cases.

The new reaction in my hands was remarkably weak in early, untreated syphilis, giving negative reactions so often as to make it useless for the diagnosis of this class of cases. To make certain that there was no mistake about the negative Bruck reaction in these cases, I repeated the tests in many of the cases, always with the same result. When this is considered along with 24 per cent. of positive reactions in nonsyphilitics, which were also carefully checked by repetition, the uselessness of the test for diagnostic purposes is apparent.

That syphilitic serum differs from most other serum in regard to the ease with which it can be precipitated has been shown in many ways since Fornet and Schereschewsky,[3] in 1907, proposed a ring test for syphilis, made by overlaying the serum in a case of tabes or paresis with the serum in a case of early syphilis. At the line of contact between the two serums, a ring of precipitate appears. Michaelis and Citron showed that mixture of syphilitic serum with extract of syphilitic liver produces a precipitate. Porges and Meier[4] devised a precipitation test by the use of an emulsion of lecithin as reagent. Klausner offered a test consisting of the dilution of active serum with distilled water, giving a precipitate in twenty-four hours in case the serum is syphilitic. Elias, Neubauer, Porges and Salomon[5] used sodium glycocholate as the precipitating reagent. To this Herman and Perutz later added cholesterin in a vain effort to perfect the reaction for diagnosis.

The Bruck nitric acid precipitation test seems destined to take its place beside these. In fact, the results obtained by Fritz and Kren[6] in their trial of the lecithin and sodium glycocholate tests were not very different from the results of the Bruck test. In a series of fifty-nine syphilitics, they obtained with the lecithin test 63 per cent. positive reactions, and in twenty-four nonsyphilitics, 50 per cent. positive reactions. With sodium glycocholate there were 65 per cent. positives in syphilitics and only 17 per cent. positives in nonsyphilitics. All the precipitation reactions show in a large proportion of syphilitics an increased amount of some substance which, however, is also present in like amount in a smaller proportion of nonsyphilitics. The fixation of complement by the combined action of syphilitic serum and extract of liver or heart remains the only property of syphilitic serum thus far discovered that is not shared by so large a percentage of nonsyphilitics as to preclude its use for diagnosis.

CONCLUSIONS

1. The Bruck precipitation test for syphilis fails in a considerable percentage of early secondary syphilis.
2. It gives positive reactions in from 24 to 28 per cent. of nonsyphilitics.

THE PHARMACOLOGY OF THE OIL OF CHENOPODIUM

WITH SUGGESTIONS FOR THE PREVENTION AND TREATMENT OF POISONING *

WILLIAM SALANT, M.D.
WASHINGTON, D. C.

The oil of chenopodium is an essential oil which is distilled from American wormseed or Jerusalem oak, a weed quite common in Maryland and in the states farther south. It first came into use in therapeutics in the treatment of ascariasis, but in recent years it has also become the chief remedy against ankylostomiasis, and is at present practically the only drug used for the eradication of this disease. As shown in the reports of the International Health Commission,[1] the number of patients treated with the oil of chenopodium is very large. It has been employed in several million cases of hookworm in the last few years.[2] Its behavior in the body is therefore a matter of considerable interest, not only to the pharmacologist, but also to those specially interested in the treatment of hookworm and other intestinal parasites. The obvious necessity of making the information concerning its action readily available suggested to me the advisability of presenting this summary of the results of pharmacologic investigations.

PHYSIOLOGIC ACTION

That the action of oil of chenopodium is not confined to the effect on the organisms against which it is directed has been established by experiments on animals. Brüning[3] was the first to call attention to its toxicity by tests on different animals, but the action of the drug has since been made the subject of more extensive investigation in this laboratory. Nelson and myself[4] have shown that oil of chenopodium is a strong local irritant, causing severe inflammation of the mucous membranes. Even very small quantities may prove very toxic and cause death when given to different animals. One-half c.c. of the oil given by mouth to a medium-sized rabbit produced symptoms of severe poisoning, such as vomiting, convulsions, coma, paralysis, and death. The active dose was smaller for cats, 0.2 c.c. per kilogram of oil of chenopodium being toxic, and 0.25 c.c. per kilogram proved fatal. Dogs were much more resistant than cats, but severe symptoms of poisoning were likewise observed in these animals. Of particular importance is the observation we made that a dose which is not effective at first may cause serious symptoms and death when repeated within one or several days. We noticed that sensitiveness to the oil of chenopodium persisted for from five to nine days. This is well worth remembering when the dose has to be repeated, as is sometimes the case, in the treatment of hookworm, for the first dose may not prove efficacious and a second or third dose is required to accomplish the desired result. Attention was also called to the effect of the nutritional condition and of diet on the toxicity of the oil. Fasting or poorly nourished animals succumbed to much smaller doses. The resistance was noticeably greater, on the other hand, in animals that had been receiving a rich carbohydrate diet for several days before the oil was given, or when the administration of the oil of chenopodium was preceded by a sufficient quantity of fatty oil, such as olive oil, coconut oil, or castor oil. Quantities which invariably caused death were survived without the production of symptoms of poisoning when any of these oils were given shortly before or after the administration of oil of chenopodium. Very satisfactory results were also obtained when several doses of about 15 c.c. of the fatty oils were given during two or three days preceding its administration. That disturbance of renal function may be caused was shown in experiments in which the permeability of the kidney was tested after the administration of the oil of chenopodium, for Bengis and myself[5] observed that fat-soluble dyes injected subcutaneously or when fed by mouth failed in some cases to be eliminated in the urine of rabbits under these conditions. Its effect on the kidney was further illustrated in another series of experiments in which evidence was obtained indicating that under certain conditions it may cause renal irritation, even when combined with some substances that were otherwise its physiologic antagonists. Albumin and casts were frequently found when it was given in an emulsion in acacia to rabbits. But when oil of chenopodium was dissolved in one of the fatty oils which, as previously mentioned, decreased the general toxicity of oil of chenopodium, renal irritation became more marked. This, as indicated in a recent report[6] from this laboratory, is probably due to the combined action of the two, that is, the oil of chenopodium and the fatty oil each producing renal irritation, the effect being enhanced when both were given together. It is important to point out in this connection that this does not apply with equal force to carnivorous animals, as the same amounts of oil of chenopodium and coconut oil fed to cats seldom produced these results.

Its poisonous nature was also shown by the tendency to cause depression of the circulation and respiration, as well as to lessen the intestinal movements. In experiments on different animals under anesthesia it was observed that blood pressure may fall considerably in some instances, as 0.02 c.c. of oil of chenopodium per kilogram when injected intravenously may

be followed by a fall of blood pressure amounting to 40 or 50 per cent.[7] Although this was not the rule, it is well to bear in mind that it occurred with sufficient frequency to serve as a warning to the clinician of the nature of the drug he is prescribing. Evidence was obtained that the action might be due to direct effect on the heart. This was also shown in an extensive series of experiments on the isolated frog heart.[8] Very small quantities proved to be quite active, as one minim of the oil of chenopodium to 100 c.c. of Ringer's fluid, when perfused through a normal frog heart, produced marked depression and sometimes arrest of the heart in diastole. In numerous observations on different animals under chloretone or morphin-ether anesthesia it was also noticed that respiration may be depressed or even completely inhibited[9] when the oil of chenopodium is injected intravenously in the form of an emulsion. That the oil of chenopodium is a general depressant is further shown by the effect produced on peristalsis.[10] The movements of the isolated intestines in intact animals may be inhibited by the oil of chenopodium. According to Muirhead and Gerald[11] uterine contraction may likewise be inhibited if the isolated organ is exposed to the oil, provided, however, the concentration is not too low.

Little is known of its fate in the body, but it might be inferred by analogy that, like other essential oils, it is conjugated with glycuronic acids. It is apparently not eliminated uncombined in the urine or in the bile for its odor in these fluids was never detected. On the other hand, its elimination by the lungs[12] was observed in experiments on animals after its intravenous administration, for the characteristic odor in the expired air was unmistakable. It is evident, therefore, from the experimental data cited above, that the drug is very active. That this also holds for human subjects is shown by the incidence of poisoning with this drug. Levy[13] reported twelve cases, nine of which were fatal. Coutant[14] reported recently one case of severe poisoning, but the patient recovered. I have been informed of several cases that have come under the observation of the medical officers of the International Health Commission.[15] The substance under consideration should therefore be handled with caution when used for internal medication as its has a tendency to affect the central nervous system, the heart, respiration, digestive organs, and the kidneys. In the presence of renal or cardiac disorders the oil of chenopodium should be given in small doses only, while in advanced cases of chronic nephritis or heart disease its use would seem to be altogether contraindicated.

As the liver undoubtedly plays an important part in detoxifying the oil of chenopodium while abnormal changes in the gastric and intestinal mucosa may accelerate its absorption into the circulation, it may be expected that in hepatic and gastro-intestinal diseases it may likewise prove more toxic. The importance of the nutritional condition in determining the toxicity of oil of chenopodium has been established by experiments on animals, as has been sufficiently indicated. This applies also to human beings. The case reported by Coutant furnishes evidence of the effects of the drug when administered to the poorly nourished and weak individual. Two doses of 10 minims each given in twenty-four hours were toxic, but the patient was 21 years of age and weighed only 95 pounds.

TREATMENT OF POISONING

Since cases of poisoning are sure to occur, the question of treatment deserves consideration. When large doses have been swallowed lavage may be resorted to with beneficial results. If carried out promptly after the oil is taken it may prove effective in preventing serious consequences, since absorption of the oil from the stomach is slow. In experiments that Livingston and I[16] carried out we often found that several hours may elapse before evidence of absorption into the circulation could be obtained, when the oil was introduced into the stomach of animals, the pylorus having been ligated previously.

The importance of not delaying lavage too long after the poison has been swallowed is further emphasized by the fact that absorption from the duodenum was found, on the contrary, to be very rapid. In some of the experiments in this laboratory the introduction of oil of chenopodium was followed by the immediate appearance of the characteristic effect on the circulation.

No chemical antidote has yet been found. The treatment in cases of poisoning would, therefore, be symptomatic. Stimulation of the respiratory and the circulatory systems would undoubtedly be of value. In experiments on the isolated heart, we found that digitalis and epinephrin are excellent antagonists. The stimulating action of digitalis has been found to be very persistent, and may comepletely overcome the depression caused by the oil. Caffein was also tried out. It, on the contrary, aided the action of the oil of chenopodium. Heart action ceased altogether when perfusion with caffein followed treatment with chenopodium. The action of caffein in poisoning with chenopodium may be different, however, in intact animals, and is being investigated in this laboratory.

While oil of chenopodium may be regarded as a safe remedy for patients in good physical condition, it should be used very cautiously in poorly nourished and weak or neurotic individuals. A diet containing a liberal amount of fats and carbohydrates, fed at least for several days before the treatment is instituted, may render the drug much safer. The routine administration of large doses of castor oil before and soon after oil of chenopodium, as recommended by Hall and Foster,[17] should be given serious consideration, as it may prove to be of prophylactic value.

Acute Intestinal Troubles in Germany.—The *Nederlandsch Tijdschrift* quotes from J. Schwalbe in the *Deutsche medizinische Wochenschrift*, No. 33, that diarrhea is prevalent, especially in northern Germany. He has been making a collective inquiry on the subject, and states that on account of the lack of bacteriologic examination it is impossible to say to what extent contagion is involved, but that in any event the bread and the poor quality of the food have certainly not a little to do with it.

THE SYNDROME OF MILD REVERSE PERISTALSIS *

WALTER C. ALVAREZ, M.D.
SAN FRANCISCO

Digestion seems to suffer very little from disturbances of secretion. Many physicians have commented on the fact that we often discover achylia gastrica accidentally in patients who have no complaint to make about their digestion. The great obstacle to making an early diagnosis of cancer of the stomach is the fact that although the mucous membrane may be almost or entirely gone, these patients ordinarily have no symptoms until the growth is large enough to block the pylorus. They will then have trouble until a channel sloughs through the tumor, after which they may be perfectly comfortable again. Similarly, there may be no complaint of indigestion after extensive resection of the bowel. Men have lived in comfort, except for an occasional diarrhea, after removal of one half of the small intestine. As Taylor[1] has aptly said, we seem to have "duplicate plants" for chemical digestion. If pepsin fails, the pancreatic ferment can come to the rescue, and when that is shut off, the gastric and intestinal ferments can, between them, do remarkably well. On the chemical side, the factors of safety are large; on the mechanical side, there is only the one muscular tube which cannot be replaced.

The conclusion, then, and it is one of the most important that the gastro-enterologist should keep in mind, is that gastro-intestinal symptoms are motor symptoms—they arise when the normal progress of the food is disturbed. We can conceive, now, of four types of motor disturbance: (*a*) speeding up of the current; (*b*) slowing; (*c*) complete stoppage, and (*d*) reversal. It is strange how little thought has been given in medical literature to the last-named possibility. We know that when a loop of bowel is distended or stimulated at any point, it can send off impulses in both directions, just as a stone thrown into a canal sends waves upward as well as downward.[2] That retrograde progress from anus to pharynx can rapidly take place has been well known since the time of Galen. All physicians have observed fecal vomiting in ileus; and many have seen the vomiting of suppositories and enemas by nervous women.[3] I have talked with a number of intelligent persons who objected to their nutrient enemas because of the bitter taste of the peptones given. Dr. Emge of this city tells me that after severe pelvic operations it has been his custom to give coffee enemas, which soon tinge the vomitus. The first time it happened he thought it was due to hemorrhage, but chemical analysis showed that it was coffee and not blood. This article could be filled with such observations culled from medical literature.[4]

It is now well known that barium enemas almost always flow back into the ileum and sometimes even into the duodenum.[5] I have seen liquid and gas pass rapidly from the colon to the duodenum in cats. The animals were anesthetized and their abdomens opened under salt solution. In order to produce this backflow, the rectum was tied off, and the colon filled with a thick soup. After this part of the bowel had become very irritable and highly tonic through its efforts at emptying, some of the material would be rushed well up into the small intestine. We know that reverse peristalsis is normal in the right half of the colon; and the return of feces from the rectum to the upper colon has been observed.[6] Boldireff and others have shown that the regurgitation of duodenal contents into the stomach is a physiologic and common occurrence.[7]

Granting, then, that reverse transport[8] of material is a common happening in the tract, and that its severe manifestations, such as fecal vomiting, are generally known, we must face the probability that milder forms are passing unrecognized. A few years ago we were diagnosing hyperthyroidism only in the cretin and in the equally deformed myxedematous; today we look for the "formes frustes" in which there is perhaps some drowsiness, a dry, hairless skin or a deficient menstrual flow. In the following paragraphs I wish to discuss briefly a few symptoms which are often found together, or alternating one with the other in the same patient, and which I believe indicate mild reverse peristalsis. The most important ones and those about which I feel surest are vomiting, regurgitation, heartburn, belching, nausea, "biliousness" and coated tongue.[9] Less important and more doubtful are globus, foul breath, and the feeling of fulness immediately after the beginning of a meal.

This article is, in many ways, a sequel to one previously published.[10] Those who have read that article will undoubtedly find it easier to understand the arguments advanced at this time. The principal point to be remembered is that the digestive tract is a muscular tube in which material moves from regions of high tone, high rhythmicity and high irritability to regions of lower tone, lower rhythmicity and lower irritability. The presence of food or of an irritating lesion in any part of the tract tends to raise the tone and irritability of that point, and in this way the normal gradient may be upset. The following experiments of Hess and Kelling may help to explain what is meant by the gradient of forces in the tract. Hess[11] put a small balloon into the bowel of a dog. A string fastened to the balloon ran out of a gastric fistula and over a pulley. At the end of the string was a little bag which could be filled with shot until its weight stopped the progress of the balloon. Eighteen cm. from the pylorus, 228 gm. were needed to balance the pull exerted by the muscle; 20 cm. farther down the pull was only 90 gm., and 12 cm. below, or 50 cm. from the pylorus, the pull was 75 gm. In a man with a jejunal fistula, I found a similar marked decrease in the pull exerted by the muscle as the balloon went down the intestine. The sluggishness of the ileum was in marked contrast to the great irritability of the jejunum. Kelling[12] has shown a reversal of these forces in dogs in which the ileum was tied just above the ileocecal sphincter. Next day, a manometer tied into the active ileum, 20 cm. above the obstruction, showed pressures varying between 10 and 20 cm. of water; while in the jejunum, the pressure was from 0 to 5 cm. It can easily be seen that under such conditions, fluids would flow backward toward the stomach.

[7] Boldireff states that in animals which have fasted for some time, intestinal juice will run out of a gastric fistula continuously in large amounts, from 100 to 300 c.c. in fifteen hours (Zentralbl. f. Physiol., 1904, **18**, 457).

[8] The term "retrograde transport" will be used in a unmber of places in which the present state of our knowledge does not permit me to say that actual reverse peristalsis occurs. More work will have to be done before we know in all cases just what type of contraction causes material to move orad.

[9] Leube has discussed just these symptoms under the title "Nervous Dyspepsia" in an excellent article in the Verhandlungen des Kongresses für innere Medizin, 1884, **3**, 204.

At times, the gradient may perhaps become leveled. In a number of cases of duodenal ulcer, I have watched contraction rings appearing in various parts of the stomach and dying out again, apparently unable to advance as waves in the direction of the ulcer. A still commoner finding with duodenal ulcer and chronic appendicitis is the stomach that fails to empty itself after six hours, in spite of active peristalsis and a patulous pylorus. Roentgenologists used to speak of pylorospasm in these cases, but more and more they are realizing that the pylorus is not always at fault. Those who have learned to milk a cow will understand more easily what I mean, when they remember that it is not powerful and rapid squeezing that brings the milk, but a coordinated contraction beginning at the base of the teat and spreading downward. Many think when the barium meal does not advance that there must be either a contracted area ahead or else that the muscle is atonic. The following experiment shows that neither of these conditions need be present:

> A rabbit was anesthetized (with urethan) and its abdomen opened under salt solution. The lower ileum was pinched with a hemostat so that the tissues were slightly bruised. After five or six hours, the bowel above the pinch was found distended with fluid, and contracting powerfully here and there. In spite of this activity and the fact that the lumen of the bowel was in no way occluded, nothing had been able to approach within 15 cm. of the injured, hypertonic region.

In my previous paper, I discussed upsets in gradient due to irritating lesions and to the introduction of food or other substances into the lower part of the tract. Since then, some work on smooth muscle has suggested another and possibly a very important way in which the gradients may be upset. I was able to show that the aboral progress of waves over the stomach is due, at least in part, to the fact that the latent period of the muscles around the cardia is less than that of the muscle in the pyloric antrum.[13] The muscle at the cardia is very sensitive to trauma or to adverse conditions, while that in the antrum is so hardy that it will often react better after it has been for forty-eight hours in the ice-box. This peculiar difference in the muscle from the two ends of the stomach is probably responsible for the fact that the gradient of latent period is actually reversed in distempered or sickly dogs. In these animals, the disease toxins apparently injure the sensitive cardiac muscle to such an extent that it reacts very sluggishly to strong currents. The antral muscle, on the other hand, generally contracts even more promptly than in normal animals. It seems very probable that this reversal of the gradient has something to do with the unwillingness of these dogs to take food.[14] Recent work, yet unpublished, shows that a similar reversal takes place in the gradient of latent period in the intestine in these diseased animals.

Very similar observations have been made on the heart. In the ascidian, the heart is a straight tube, one end of which acts for a while as pace-maker because it is the region of highest rhythmicity. It suffers most from fatigue, however, so that before long the other end of the heart is left with the higher rhythmicity; this now takes the lead, and the blood current is temporarily reversed. A similar upset takes place from time to time in the selachian heart.[15] Although the gradient is more stable in the hearts of higher forms of life, it has recently been discovered with the string galvanometer that a number of supposedly normal dogs have atrioventricular rhythm, that is, the gradient of rhythmicity in their auricles is reversed[16] In some human cases, a reversal has been observed which has righted itself as the patient improved in general health.[17] It seems to me very likely that the steepness of the gradient of forces in the gastro-intestinal tract varies a great deal, not only in different people, but at different times in the same person. The dyspeptic who goes on a vacation probably develops a steeper gradient; rough food will then be carried along without "hanging up" anywhere; his indigestion will go and his bowels will move normally.

Perhaps we can explain in this way the nausea and vomiting of nervous, worn-out women. Some of the most striking manifestations of reverse peristalsis are observed in the hysterical. Roentgenographic examinations and exploratory operations often reveal nothing to account for the trouble, and it can be cured only by rest and overfeeding.

VOMITING

The progress of gastro-enterology has been greatly hampered by the idea that the stomach is the organ of digestion. Even physiologists have been so blinded by this idea that very few of them have paid any attention to the behavior of the intestine during vomiting. My own experience soon convinced me that vomiting may begin with increased tone and activity in the jejunum.[18] I was able to confirm Ewald's statement that in ileus the stomach is filled with intestinal contents long before fecal vomiting appears.[19] Vomiting has been produced in dogs by reversing stretches of jejunum, so that the current would set backward toward the stomach. These dogs could be kept alive and comfortable if fed soft foods slowly. Large meals or rough food would be rejected.[20] It has been shown repeatedly that the vomiting is not due to the irritation of bile and pancreatic juice in the stomach,[21] so I believe it must often be due to, and part of, the reverse peristalsis beginning in the bowel. It should be noted that vomiting is often severe with low intestinal lesions and that it may be entirely lacking in serious gastric disease, such as ulcer and carcinoma (without pronounced pyloric obstruction).[22]

[18] Openchowski (Zentralbl. f. Physiol., 1889, **3**, 4), in describing vomiting says, "In the beginning, great activity of the intestine" (anfangs starke Unruhe der Gedarme). Poensgen says waves have been observed to travel from the duodenum on to the stomach in vomiting (Motor Verricht. d. menschl. Magens, 1882, p. 8). Similar statements have been made by Wepfer, quoted by Brinton (Cyclopedia of Anatomy and Physiology, London, 1859, **5**, 317) and by Muller (Handbuch der Physiologie, 1835, **1**, 485). Boldireff noted, during some experiments, that periods of intestinal activity were often accompanied by vomiting (Zentralbl. f. Physiol., 1904, **18**, 489). I once attended a child with severe recurrent vomiting in whom the attacks were preceded by violent intestinal peristalsis and borborygmus loud enough to be heard across the room. I have also seen vomiting of the food given through a jejunal fistula. Such feeding must be done very slowly with the food exactly at body temperature. Vomiting has been observed also in feeding by duodenal tube (Stockton: Diseases of the Stomach, New York, D. Appleton & Co., 1914, p. 81).

Vomiting is often severe in pregnancy and with some lesions of the pelvic organs. I refer here not to the so-called "toxemic" but to the "reflex" or "nervous" type of vomiting. I believe the uterus in some way influences and raises the tone, irritability and activity of the lower part of the bowel, so that there is a tendency to reverse peristalsis. The greater activity of the colon may be due to its sharing in the hyperemia of the pelvic organs.[23] It is conceivable also that there may be a spread of tone along the pelvic nerves. Elliott and Barclay Smith found that they could raise the tone of the midregion of the colon, and produce anastaltic waves by stimulating these nerves in animals.[24] This tendency to reverse peristalsis in pregnancy was well recognized by Campbell[25] who suggested that we utilize it in giving nutrient enemas in the vomiting of pregnancy. He felt sure that these enemas would be carried well up into the small intestine where they could be digested and absorbed. It is interesting that the ancients also recognized this tendency to anastalsis. The Brugsch papyrus advises, as a test for pregnancy, the giving of pounded watermelon in milk; if the woman has flatulence only and no vomiting, she is not pregnant.[26] Hippocrates used "hydromel" in much the same way.[27] It is not a bad idea that an irritant not sufficient to upset a normal tract might be able to reverse one that already was tending that way.

It seems to me that those who ascribe the vomiting of pregnancy to toxins derived from the fetus do not pay enough attention to the fact that exactly similar phenomena are seen in many women on the first day of menstruation, at the menopause and with some pelvic diseases, such as dragging displacements, fibroids and pus-tubes. There is a large literature on this subject, and the symptoms enumerated are those discussed in this article. They often disappear immediately after hysterectomy, ventrofixation, etc. I have seen similar disturbances in a few men with large prostates and distended bladders.[28] It does not do any good to call these troubles "reflex" when the path cannot be pointed out. Gaskell's research has absolutely demolished Robinson's idea that the solar plexus is an "abdominal brain" with reflex centers.[29] The stormy vomiting and dynamic ileus often seen after pelvic operations may be due to a great and sudden increase in the irritability of the colon. One may also explain in this way the severe gastro-intestinal upset seen sometimes after injury to the testis.[30]

REGURGITATION

Vomiting shades off into regurgitation in many cases.[31] People will taste certain foods all day; particularly fats, which tend to return from the bowel into the stomach.[32] Often in duodenal ulcer, gallbladder disease and chronic appendicitis there will be regurgitation of bile-stained fluid before breakfast. Some women regurgitate only at the beginning of the menstrual period. Troublesome regurgitation may cease a few minutes after the patient has a bowel movement. The distention of the pelvic colon may have been keeping that region overactive and causing it to give off reverse waves.[33] These waves need not be so powerful that they sweep material along before them. Some time ago, while recording the activities of seven different regions of the rabbit's intestine on the same drum, I found that short peristaltic rushes here and there were originating in ripples that were coming, unnoticed by the naked eye, all the way from the pylorus.[34] In the same way, I believe it probable that ripples coming from a full and overactive colon, or from the irritable ileocecal region in appendicitis, will run up the bowel and show themselves in the stomach and esophagus as waves of acid regurgitation. The objection may be raised that the connective tissue block at the pylorus which prevents the spread of gastric waves on to the duodenum will likewise prevent the upward spread of reversed waves. I think, however, that since my records from the cat's intestine show that ripples beginning in the duodenum generally coincided with, and probably were part of, waves arriving at the pylorus, it is quite possible that ripples going in the opposite direction can also pass the barrier.

The following case is very suggestive: A constipated infant regurgitated so much that her pillow was always soaked. After weeks of this her bowels suddenly became a little loose, and the day this occurred, the mother was surprised to find the pillow perfectly dry. It remained that way for over a week, until the bowels became constipated again. Apparently the establishment of a good current downward instantly

---

21. The duodenum has been closed off in man so that all secretions had to go through the stomach on their way to the jejunum, and yet there was no trouble (Moynihan: Brit. Med. Jour., 1901, **1**, 1136). Chlumski performed similar operations on dogs without causing them to vomit (Beitr. z. klin. Chir., 1898, **20**, 519-523). Cholecystogastrostomy in man and dogs does not produce vomiting (Oddi: Confer. Clin. ital., Milan, 1897, **1**, 77). See also Kolbing: Beitr. f. klin. Chir., 1902, **33**, 518. 22. Faulhaber and von Redwitz: Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1914, **28**, 157. Cohnheim and Dreyfus produced vomiting in dogs by distending a balloon in the intestine. They found that a slowing of gastric motility could easily be effected by irritating the bowel, whereas it was not observed after the production of a severe gastritis. They point out that we must look more to the intestine for the cause of gastric disturbances (Ztschr. f. physiol. Chem., 1908, **58**, 56, 82).

23. Carnot and Glenard noticed while perfusing the excised intestine that its activity was greatly increased when the blood flow was more rapid (Compt. rend. Soc. de biol., 1912, **72**, 496, 661). An increased activity of the colon might account for the looseness of the bowels in many women during menstruation.

24. Elliott and Barclay Smith: Jour. Physiol., 1904, **31**, 282.

25. Campbell (Tr. Am. Gynec. Soc., 1878, p. 268) says that the woman with pregnancy or pelvic disease has an irritable tract in which "response is usually by inverted rather than by direct action: eructation, regurgitation, nausea, vomiting, constipation, far more frequently than diarrhea and other manifestations of downward action. The tract gets into the habit of retrostalsis."

33. Smith and Lewald say, "The frequency with which colic accompanies regurgitation is suggestive of their commoin origin." The waves causing regurgitation may arise in the overactive part of the intestine where there is colic (Am. Jour. Dis. Child, April, 1915, p. 271).

34. Alvarez, W. C.: Am. Jour. Physiol., 1915, **37**, 273.

stopped all regurgitation upward. The ancients not only gave purges to stop vomiting, but they stopped excessive purgation by giving emetics.[35]

HEARTBURN

Before giving my views as to what heartburn is, I must emphasize what it is not. A good many years ago I was surprised to find that only a small proportion of the patients complaining of sour stomach and heartburn have an actual increase in their total acidity and free hydrochloric acid. Titration of the burning fluid that was being regurgitated often showed subacidity, and gastric analyses made during periods of discomfort did not show values any higher than those made during periods of relief. A review of the literature showed that similar observations have been made by every writer who has done any work on the subject.[36] As far back as 1884, Reichmann[37] stated clearly that although it might be customary for laymen and physicians to ascribe heartburn to an increase in gastric acidity, such an increase could only occasionally be demonstrated.

This fact is not so surprising when we remember that almost all of those who have put from 0.5 to 2 per cent. hydrochloric acid into the human stomach by tube agree that the mucous membrane cannot sense it as pain or heartburn.[38] At most, there is a slight feeling of warmth. A number of writers assert that the diseased stomach is so hyperesthetic that it can feel the acid. Talma and his pupils found in a few cases with possible ulcer that the acid would cause pain, rarely burning.[39] This idea of a hyperesthetic mucous membrane has been discredited, however, by the work of Hurst,[40] Löwenthal[41] and Schür,[42] who showed that persons with ulcer, demonstrated later at operation, could not feel the acid any more than normal persons can. It might also be remarked that heartburn is not a common complaint with gastric ulcer. Recently the work of Ginsburg, Tumpowsky and Hamburger[43] indicates that pain felt by ulcer patients on the introduction of acid is due not to a direct irritation of the nerve-endings, but to powerful contractions set up by the acid. Some writers adopted the idea of "hyperaciditas larvata"—a hyperacidity which is present long enough to produce symptoms, but which disappears about the time the stomach tube is passed. Schmidt thought the persons with pain and heartburn must have lost a protecting layer of mucus over the gastric lining.

It seems to me that the true explanation is the one given by Reichmann[37] thirty-three years ago. He had people swallow a little gelatin-coated sponge on the end of a string. This was left for ten minutes in the esophagus just above the junction of the middle and lower thirds. It was found that the fluid expressed from the sponge was acid in the persons who had heartburn and alkaline in normal controls. He concluded, therefore, that heartburn is due to the regurgitation of more or less acid gastric juice through a relaxed cardia into the esophagus. This view has been held independently by a number of observers. Some doubt has been cast on it by the work of Hurst,[40] who states that the esophagus is not sensitive to acid. This seems strange in view of the fact that those who have experimented with acid have had to give it by stomach tube so as to avoid burning sensations in the pharynx and esophagus. The lower pharynx seems to be much more sensitive than the esophagus, and most persons feel the heartburn in the back of the throat.[44] Further work is needed before we know just where and how the acid causes burning. Some of my patients who take dilute hydrochloric acid complain of burning, others do not. I have experienced severe and typical heartburn after drinking "acidol"[45] in water. Some nervous women complain at times of a burning feeling in the epigastrium, as if the stomach were "on fire." This is probably an entirely different thing—a paresthesia which at times moves down over the right hip, showing that it has nothing to do with the stomach.

To my mind the most suggestive thing about true heartburn is its well known association with belching and regurgitation. Patients often say they feel the burning when the fluid comes up. Occasionally it is worse when the sufferer is lying down, perhaps because the gastric juice can then more easily run back up the esophagus. It is often brought on by eating fats which, as I have already pointed out, favor regurgitation. This may be due to the fact that they depress gastric activity while at the same time they stimulate the bowel. Many men suffer from heartburn after using tobacco. In habitués, some regurgitation of gastric juice probably represents the nausea and vomiting of the neophyte.

Many persons with heartburn are relieved by taking alkalis. These drugs may do good in two ways: first, by neutralizing the acid in the stomach, and secondly, by enabling the patient to belch so noisily and satisfactorily that he does not feel the need of doing it again for the rest of the day or night. When there is no regurgitation and belching, there is rarely any heartburn. The fact that many people with subacidity are relieved by soda shows that its virtues are not due entirely to its antiacid effect. I have seen a few persons who were made worse by alkalis and were immediately relieved by the administration of hydrochloric acid. I was led to try this by Cannon's[46] observation that an increase in gastric acidity closes the cardia

---

[35] Paulus Aegineta: London, 1847, **3**, 489, 499. Hippocrates also recognized the possibilities of reversing the current. He says, "In confirmed diarrhea, vomiting, when it comes on spontaneously, removes the diarrhea" (Adams' Translation, New York, **2**, 252).

[36] Schütz made a careful study of 830 cases, and concluded that only a small percentage of people with hyperacidity have symptoms (Wien. med. Wchnschr., 1906, **56**, 2241-2410). [44] On numberless occasions I have seen barium-containing *milk* thrown quickly and forcibly back into the upper part of the esophagus. This seemed to be due to powerful contractions of the muscle near the cardia. It must be remembered that sensations derived from the esophagus between the clavicles and nipples may be referred either upward into the throat or downward to the epigastrium (Boring: Am. Jour. Psychol., 1915, **26**, 34).

[45] Hydrochloride of betain, which liberates hydrochloric acid in solution.

[46] Cannon: Am. Jour. Physiol., 1908, **23**, 105.

bowel.[52] A review of the literature on the vagus shows that this is not improbable. May[53] found the inhibitory effects more pronounced on the cardiac than on the pyloric end of the stomach. Stimulation of the vagus has produced regurgitation of intestinal contents into the stomach and even vomiting.[54] Very similarly, in the heart of the frog or turtle, vagal stimulation tends to reverse the impulse because it depresses the sinus and leaves the auriculoventricular region active. This is more likely to occur in hearts which have been experimented with awhile and in which the sinus region has become disproportionately fatigued.[55]

Some people experience nausea when constipated, and are relieved immediately after emptying the rectum. Nausea may be associated with diarrhea also, if the bowel is trying to clear itself both ways from some irritated region. It is very common to see nausea produced by cleansing enemas. In one of my patients this occurs only if the enema is made irritating by the addition of much salt or soap. Incidentally, Nothnagel and others[56] have shown that the addition of salt to liquids injected into the bowel will cause them to travel much farther up the tract. It is interesting that the ancients gave hellebore by mouth to purge and by rectum to produce vomiting.

COATED TONGUE AND FOUL BREATH

It is commonly supposed that the tongue, in some sympathetic way, reflects the condition of the gastric mucous membrane. I can find no proof of any kind for these views. They seem to be based on the idea, unfortunately still too prevalent, that most gastro-intestinal upsets are due to a gastritis. Recent, more exact necropsy studies, and the examination of tissues secured at operations have failed to reveal the expected changes.[57] Inflammatory changes were strikingly absent even in the stomachs of a series of alcoholics dying in delirium tremens.[58]

It seems to me that by far the best explanation of the coated tongue has been given by Kast.[59] He gave lycopodium powder in sealed capsules to a number of persons, and was able to recover the typical spores in the mouths of most of them the next morning. I have repeated these experiments, and have found no difficulty in confirming them. In one case, of a woman who regurgitates a good deal, particularly during the menstrual period, the tongue's coat became yellow from the lycopodium.

It is possible that the particles on the tongue may come from even below the stomach. Grützner and others[60] have shown in animals and in man that lycopodium spores or other finely divided and easily recognizable material, given in enemas, will travel in a few hours from the rectum to the stomach. Closely corresponding to these experiments are those of Uffenheimer, Dieterlen and others,[61] who found that tubercle and prodigiosus bacilli injected by rectum could be recovered from the pharynx a few hours afterward, when every precaution had been taken to prevent the animals from licking themselves anywhere or touching their feces. Transmission through the blood stream was also fairly well ruled out.

Laymen and physicians often hold the view that the bad breath associated with "biliousness," a coated tongue, a "dark brown taste" and constipation is due to the exhalation of absorbed toxins. The experiments previously quoted show that the foul breath may just as easily be due to the presence of actual colonic material on the back of the tongue. If these reverse currents are so strong in apparently normal persons, it would not be surprising if they were stronger in the diseased. It goes without saying that these reverse currents must not be blamed for the coated tongue or foul breath in any particular case, until other possible causes in nose, mouth and pharynx have been ruled out.

GLOBUS

Some of us have been unfortunate enough to swallow while a wave or regurgitation was coming up, and we have felt a painful, tearing feeling as the two waves met. It seems to me that this may be the mechanism of globus.[62] Some persons describe it as a wave ascending or descending along the esophagus. It is suggestive that the hysterical, who are supposd to suffer most from globus, often exhibit the most pronounced symptoms of intestinal antiperistalsis.

A FEELING OF FULNESS AFTER TAKING A FEW MOUTHFULS OF FOOD

In rare cases this will be due to shrinkage of the stomach, brought about by extensive carcinoma or ulcer. Ordinarily, persons with this symptom will be found to have large or even baggy stomachs. Carlson's experiments agree with those previously reported in showing that the sensation of fulness does not originate in the gastric mucosa.[63] Leven and Barrett[64] have commented on the fact that persons who wake in the morning with the feeling that their dinner has not passed on really have empty stomachs, as shown by the roentgen ray. Similarly, Hurst[65] has found empty stomachs when the patients were sure that they were filled with gas. He found some patients with gastro-enterostomy who complained of a feeling of fulness if their stomachs emptied too rapidly into the bowel. Similar distress is caused by feeding too rapidly through a jejunal fistula.

This complaint of fulness is common with chronic appendicitis, in which it is often associated with other signs of back-pressure. Just as the taking of a little food causes the terminal ileum to empty into the cecum, a failure of this emptying to take place may delay the emptying of the stomach and duodenum, and may, I believe, cause this feeling of fulness.[66]

---

[52] It is not generally known that large branches of the vagus go directly to the upper part of the jejunum (Alvarez, W. C.: Am. Jour. Physiol., 1915, **37**, 276. Mackenzie: Proc. Roy. Soc., 1915, **9**, Electrother. Sect., p. 7; Jour. Anat. and Physiol., 1917, **51**, 287. Gaskell [Note 29]).

BILIOUSNESS

It is well known by thinking physicians today that we have no reason for ascribing this syndrome to hepatic insufficiency. It has probably derived its name from the fact that these persons often find bile in regurgitated or vomited material. It has already been pointed out that the presence of a certain amount of bile in the stomach is normal, and any excess would not indicate disease of the liver so much as an increase in reverse peristalsis. Persons who get severe "bilious" attacks with vomiting, nausea, regurgitation of bile, coated tongue, headache, etc., will, I think, be found ordinarily to have a chronic appendicitis. Their symptoms are really those of reversed intestinal activity.

The relief that these persons may derive from a dose of calomel is not due to any action on the liver,[67] but, I believe, to a restoration of the normal currents down the tract. In milder cases, the back-pressure may be due to constipation—the current cannot go forward, so it tends to be reversed. It seems to me that a laxative brings instant relief, not by clearing out toxins, but by removing the material which was obstructing and irritating the colon.

CONCLUSION

An attempt has been made to explain a number of gastro-intestinal symptoms in the light of recently acquired physiologic knowledge. I believe that the underlying cause of all of them is a reversal of the currents in the tract. Thus, vomiting is often due to reverse peristalsis in the intestine; regurgitation is a mild form of vomiting; heartburn is due to the regurgitation of gastric juice into the upper esophagus; belching is closely akin to regurgitation; nausea is probably one of the ways in which we perceive reverse peristalsis; "biliousness" is the common name for the reverse peristalsis syndrome; a coated tongue and foul breath are often the results of regurgitation; globus is due to reverse waves in the esophagus, and the feeling of fulness after taking a few mouthfuls is often due to back-pressure in the intestine.

Those who may feel that I have appropriated nearly all of the gastro-intestinal symptoms for this syndrome are asked to remember that if, as seems likely, symptoms are produced almost entirely by disturbances in the motor functions, we should be most conscious of, and most annoyed by, the severest possible form of such disturbance, namely, a reversal of the current.

The question may also be asked, If reverse peristalsis is so common, why do we not see more of it with the roentgen ray? Moreover, how can signs of reverse peristalsis appear from time to time during the progress of digestion, when food is actually going down the tract? First, it must be remembered that most of the disturbances are due probably to ripples coming up the tract. Any oarsman knows that a wave will not carry his boat more than a few feet unless he is very near a shelving beach. My records have shown that ripples can come down the intestine long distances without forwarding the contents, and can then break into strong waves which rush material along before them. I see no reason why similar ripples cannot travel upward in the wall of the bowel until they show themselves as waves in the stomach and esophagus. When the gradient of forces in the tract is poor, waves can probably travel in either direction. When the stomach is full and active, it will be easier for waves to proceed aborally; when the stomach and small intestine are empty and the colon is full, the waves will more easily ascend. Moreover, animal experiments indicate that the gradient may not be upset to the same extent in all parts of the tract, so that, for instance, reverse waves might be present in the stomach, and normal ones in the bowel. Similarly, the heart that is beating with nodal rhythm sends the blood in the proper direction, although the ventricles are contracting before the auricles. It is conceivable that ripples can ascend the digestive tract even when the gradient is not reversed. To explain what I mean, I will point to the case of a large river like the Missouri, which undermines its banks in places until tons of earth tumble in. In the lower stretches of the river, where the current is not rapid, such a commotion might cause ripples to run a quarter of a mile uphill, and over water flowing in the opposite direction.

Another reason why we cannot expect to see much reverse peristalsis with the roentgen ray is that even normally we cannot follow the food in the small intestine after it leaves the duodenum, and before it reaches the terminal ileum. Actual reverse transport of material has been observed in those parts of the tract which are accessible to roentgenographic study. Twice I have seen definite reverse peristalsis in stomachs free from organic disease. Subsequent operation revealed the cause to be, in one, appendicitis, in the other, duodenal ulcer. More important than visible reverse waves are the reversed impulses that hold back the barium here and there in the tract, in spite of the fact that the muscle is active, and the tube ahead is unobstructed. These are the conditions we see every day.

Many physicians today are satisfied when they have appropriately labeled each case as a "gastritis," a "hyperacidity" or a "biliousness." Their work then ends, as each label carries with it a certain string of prescriptions and, perhaps, a diet. I believe that this paper will have been well worth writing if it helps at all in making men dissatisfied with some accepted ideas, and more inclined to think in terms of disturbed physiology. Such thinking must make for better therapeutics. The physician will more often seek for and find the lesion that is irritating the bowel and giving off the reverse waves. More often, also, will he see the hopelessness of medical "tinkering," and will call in the surgeon at once. If such radical treatment is inadvisable or impossible, he will use a smooth, cellulose-poor diet, which will flow more easily along the impaired gradient. He may, perhaps, be able to improve the gradient by resting and overfeeding the patient. Later, when the pharmacologist gets to thinking along these lines, he may find for us drugs which will restore the downward currents, either by increasing the activity of the upper part of the tract or by decreasing the activity of the lower parts. I hope soon to publish the report of work indicating that some laxatives do alter the gradient in these ways.

THE TREATMENT OF LEUKORRHEA WITH LACTIC ACID BACILLI *

FRANK BENTON BLOCK, M.D.
AND
THOMAS H. LLEWELLYN, M.D.
PHILADELPHIA

It is our purpose to give a brief summary of the experiences that we have had in the treatment of leukorrhea by means of the local application of lactic acid bacilli. Our work has extended over a period of two years, which we regard as a sufficient length of time thoroughly to digest our results, and separate the wheat from the chaff of overenthusiasm. Much has previously been done by other investigators in the search for a cure in obstinate cases of leukorrhea, and although we shall not quote the work of others, we gladly give credit and priority wherever it may be due.

Normally, in the healthy adult virgin, the reaction of the viginal secretion is acid, as a result of the activity of the bacillus of Doederlein. In the patient who is suffering from chronic leukorrhea, however, with the exception of one type, of which we shall speak later, the reaction of the vaginal secretion is distinctly alkaline. After observing these facts in a large series of cases, we formulated the theory that if we could change the reaction of the vagina from alkaline to acid, and maintain an acid reaction, we might be able to control or, perhaps, cure the leukorrhea.

The use of chemicals, drugs and douches was immediately discarded from our work, for the reason that previous experience had shown them to be but ephemeral in effect, and utterly inadequate, so far as anything like a lasting result is concerned. Believing that the alkaline reaction of the vagina in cases of leukorrhea was due to the activity of saprophytic bacteria, which in their proliferation completely killed the normally present Doederlein bacilli, we felt that if we implanted into the vagina a nonpathogenic, acid-forming organism, we could overgrow these saprophytic organisms, and our problem would be solved. At this point let us state that, although our results have been encouraging in many ways, the problem proved to be entirely different when put to a practical test.

Although many organisms might have been used in this work, we selected the Bulgarian lactic acid bacillus because of its accessibility, and also on account of the enthusiastic reports of its use in intestinal saprophytic conditions. Through the kindness of two pharmaceutical laboratories, we were supplied with tablets of lactic acid bacilli and bouillon cultures of the same organism. These, together with a stock culture obtained from the William Pepper Clinical Laboratory of the University Hospital, constituted the source of our supply.

In the beginning of our work we gave all the organisms an equal trial, and found that the best results were to be obtained from the use of bouillon cultures, provided the culture was reasonably fresh. As a practical measure, however, we soon learned that the use of cultures was out of the question, on account of the difficulty of always having a fresh culture on hand. In contradistinction to this drawback in the use of cultures, we found that the organisms compressed in tablet form with lactose were reasonably active and potent over periods of many weeks, provided the simple precaution of keeping the tablets on ice was observed. To satisfy ourselves that this was the case, we had several of the tablets from one laboratory cultivated and obtained living organisms. Without going into unnecessary detail regarding the various methods of application that we have employed in the development of our work, we shall, at present, merely describe the technic we employ, and then summarize the results obtained in the various types of cases treated.

TECHNIC

The patient is placed in the usual dorsal gynecologic position, and a thorough pelvic examination made, including smears, when indicated. A bivalve speculum is then inserted into the vagina, and the cervix and the upper vaginal canal exposed. The reaction of the vagina is then taken by moistening a piece of litmus paper in the vaginal secretion, after which the vagina is thoroughly cleansed of mucus and leukorrheal discharges by means of a simple alkaline spray, and the vagina is then dried with cotton pledgets. A lactic acid tablet, perferably one that is readily soluble and made with a lactose base, is placed in a medicine glass and moistened with *one or two drops* of sterile water dropped on the tablet by means of a small pipet or eye-dropper. It is important not to supply more than a very few drops of water to the tablet; otherwise the tablet will completely disintegrate and cannot be readily handled.

If the proper kind of tablet is used, and only enough water is applied to moisten it, it will attain the consistency of thick cottage cheese, and may be readily lifted in toto by a pair of forceps. It is then placed in the upper vaginal canal, and spread over the walls and on the cervix by means of the forceps. If the tablet is of the proper consistency, it will adhere to the vaginal mucosa wherever placed, and will show no tendency to run out of the vagina, as is the case with ordinary solutions. The speculum is next withdrawn half way, with its blades open, to allow the upper vaginal canal to close over the tablet that has been applied. Finally the blades are closed and the instrument is withdrawn. No tampons are applied. The patient is instructed to return in a week, and all douching is absolutely interdicted. On her return, the same technic is repeated, and she returns once a week for a reimplantation of the bacilli, until the vagina is acid—a result which in a favorable case is attained in about three or four weeks. After the reaction has become acid, no treatment is given so long as it remains so, although the patient returns at gradually increasing intervals to have the reaction taken. In favorable cases it is usually found necessary to reimplant organisms at intervals of from three to four weeks, since, after that time, the organisms seem to die, or at any rate to lose their potency. We might, therefore, state here that the treatment is seldom a permanent cure but rather a good palliative measure, requiring attention about once a month and superseding douches.

TYPES OF CASES TREATED, AND RESULTS

The cases that we have subjected to this treatment might be conveniently classified in the following groups, which we shall consider separately: vulvovaginitis of children, specific and nonspecific; endocervicitis, both simple and gonorrheal, and senile vaginitis, natural and artificial.

In the treatment of vulvovaginitis in children this method is of little avail as long as gonococci are apparently present. When, however, the gonococci have largely disappeared, the use of the lactic acid bacilli seems to be of some value in reducing the discharge and in lessening the vaginal irritation. In many cases, however, the symptoms will return on the cessation of the treatment. In the nonspecific types of vaginitis in children, the results are more encouraging and in a good percentage of the cases treated, we believe that a cure has been established. As some difficulty is often encountered in the introduction of the bacilli into the vagina of children, we have of late introduced the dry tablet into the vagina, and then injected a few drops of water, thus allowing the tablet to dissolve inside the patient. An interesting point we have noted in connection with our work with children is the fact that, before the onset of menstruation, the reaction of the child's vagina is almost constantly alkaline, whether or not disease is present; and it was with considerable difficulty that we obtained an acid reaction in some of these cases.

---

* From the Department of Gynecology, University of Pennsylvania School of Medicine.

In the consideration of leukorrheal discharges during the childbearing period, we wish to call attention to the fact that our results were practically nil in cases in which there was a gross pelvic pathologic condition. Similarly, we have nothing encouraging to offer in the treatment of gonorrheal endocervicitis, or when cervical erosion, laceration, or another evident pathologic condition is the cause of the leukorrhea. Such conditions must be treated along the usual lines before any attempt is made to apply the lactic acid treatment. After the exclusion of such cases as we have mentioned, there will be a large number of cases in which the leukorrheal discharge is the chief symptom, and in which no definite disease can be determined. Cases of this type we have classified under the heading of nonspecific catarrhal endocervitis. They will almost uniformly present an alkaline reaction in the vagina, and, in approximately 50 per cent. of the cases, will respond to the treatment we have suggested.

Finally, we come to the consideration of senile or atrophic vaginitis, that most distressing condition which occurs in women past the menopause, characterized by a thin, yellow, malodorous, irritating discharge, and accompanied by intense itching of the genitalia, and sometimes by urinary frequency and burning. The cause of this syndrome is the lack of ovarian internal secretion, due either to natural atrophy of the glands at the time of the normal menopause, or else to their surgical removal. It is in this type of case especially that we have had our best results, and the strange fact is that these cases always show an acid reaction of the vaginal secretions. But, notwithstanding this fact, the application of lactic acid bacilli gives prompt relief, which we have interpreted as being due to the overgrowth of acid-forming saprophytes by the less irritating lactic acid bacilli.

These patients, as a rule, have no relief from douches, or local applications of the usual remedies, and wander from one dispensary to another in search of a cure. Their plight is distressing, and as most of them have been treated by many other physicians before coming into our hands, we feel particularly gratified with the results we have obtained. It must be distinctly understood, however, that we do not claim to have obtained a permanent cure in any of these cases, although we do know that many of them have gone several months without treatment and without symptoms. In the average case, it is necessary to implant the bacilli at monthly intervals, with perhaps a few months' intermission occasionally. While we shall not give actual figures, we believe that 80 per cent. of our cases of senile vaginitis, whether following the natural or the artificial menopause, have responded to this treatment.

CONCLUSION

We wish to state that this work is offered merely for what it may be worth, and we feel that in selected cases it will constitute a most effectual palliative treatment, being particularly acceptable to the patient on account of the cleanliness and convenience that are consistent with its proper execution.

1503 Girard Avenue—715 North Fortieth Street.

THE ALKALI RESERVE IN THE BLOOD OF PELLAGRINS *

JAMES W. JOBLING, M.D.
AND
ELMER S. MAXWELL, M.D.
NASHVILLE, TENN.

The incidence of pellagra in the Southern States has increased rapidly during the past ten years, but in spite of the advances which have been made in prophylaxis and in treatment, its etiology is still in doubt.

Various views have been advanced by investigators to explain the etiology of pellagra. These views may be divided into two classes: those which deal with it as a communicable disease, and those which consider it to be due to an unbalanced diet. Numerous organisms have been described as the etiologic agent, but sufficient proof has not yet been offered to justify us in accepting any of them. Two conceptions have been advanced by those who believe pellagra is caused by an unbalanced diet. One group of observers believes it is due to the lack of some essential substance in the diet, while the other considers it an intoxication due to the excessive use of some particular kind of food.

It has also been suggested that the disease may be caused by a change in the alkali reserve of the body. Thus, Fairbanks[1] says pellagra is caused by an acidosis resulting principally from phosphoric acid and purins in the blood, though he does not mention the particular kind of food which is responsible. Carmichel,[2] on the other hand, advocates the theory that pellagra is due to an increase in the alkalinity of the blood caused by the excessive ingestion of fruits and vegetables. It is, of course, well known that certain foods used in large amounts may cause a change in the alkali reserve of the body.

In view of these statements, we decided to report at this time the results obtained in a study of the alkali reserve in the blood of pellagrins.

The study was made with a series of thirty-six patients, including fatal cases, acute cases in which there was subsequent recovery, and chronic cases in which the patients were suffering from recurrences. Van Slyke's[3] method of estimating the carbon dioxid combining power of the blood plasma was used. The results are given in the accompanying tables.

---

* From the Departments of Experimental Medicine and Pathology, Vanderbilt University Medical Department.

[1] Fairbanks: Texas State Med. Jour., 1916, **21**, 170.

[2] Carmichel: Paper read before Tennessee Medical Association, April, 1917.

[3] Van Slyke: Jour. Biol. Chem., 1917, **30**, 347.

By reference to Table 1, it will be seen that all acute cases except Case 31 came within the normal limit, the average of the acute cases being 61.63 volume per cent. carbon dioxid. The five fatal cases (Cases 14, 16, 20, 31 and 32) averaged 58.6 volume per cent. The chronic cases (Table 2) give an average lower than the acute, though it is well within the normal. The average value of all cases is 59.45 volume per cent. The values for the males and females did not differ.

TABLE 1.—RESULTS IN ACUTE CASES

Case No. and Age	Color and Sex*	Carbon Dioxid Volume, Per Cent.
2—55	W—♀	66.0
3—27	W—♀	67.0
4—47	W—♀	67.0
5—16	W—♀	56.0
6—14	W—♀	59.5
7—10	W—♂	64.3
11—23	W—♀	68.0
12—56	W—♂	66.2
13—77	W—♀	64.3
14—70	W—♀	69.1
15—32	W—♀	67.1
16—30	W—♀	63.4
17—56	W—♂	65.5
18—25	W—♀	54.0
20—44	C—♀	57.9
27—36	W—♀	55.0
29—22	W—♀	57.0
31—41	C—♀	52.0
32—29	C—♀	60.0
34—40	W—♀	53.4

Average of 20 acute cases 61.63

* In the tables, ♂ indicates male and ♀ female.

The averages for the children are somewhat less than those for the adults. Most of the patients were seen at the Davidson County Pellagra Hospital, where the diet was well balanced, though high in proteins. The blood was taken from a number of the patients immediately after admission to the hospital and again at a later date. Thus we found that the change in diet and environment did not perceptibly alter the alkali reserve of the blood.

Viscosity determinations were made on the blood of seventeen patients. Traube's stalagmometer was used.

TABLE 2.—RESULTS IN CHRONIC CASES

Case No. and Age	Color and Sex	Carbon Dioxid Volume, Per Cent.
1—50	W—♂	57.0
8—65	W—♂	59.5
9—60	C—♂	67.2
10—45	W—♂	72.0
19—62	W—♂	53.0
21—12	W—♂	52.6
22—39	W—♀	58.8
23—67	W—♂	54.3
24—68	W—♂	55.4
25—55	W—♀	54.8
26—12	W—♀	56.9
28—39	W—♀	54.0
30—69	W—♂	54.0
33—68	W—♂	54.9
35—28	C—♀	56.0
36—49	W—♀	58.0

Average of 16 chronic cases 57.27

The tube was graduated so that at 20 C. (68 F.) 20 drops of alcohol would pass through in one minute. The blood was obtained by venipuncture and drawn into a sterile, dry tube. It was immediately transferred to a centrifuge tube containing dry potassium oxalate crystals in sufficient quantity to make a 1 per cent. solution. The blood was then centrifuged for fifteen minutes in a high power centrifuge, which effectively threw down all cells and platelets, leaving a clear, colorless plasma. The number of drops passing through Traube's stalagmometer in six minutes was determined, and the average for one minute taken. We found the blood from the seventeen pellagrins to be less viscid than that from twelve normal individuals. As the difference was not great, however, we do not care to make any deductions from it.

CONCLUSIONS

The alkali reserve of the blood in pellagra does not vary from normal in either the acute or the chronic cases; therefore there is no acidosis or alkalosis in pellagra.

The viscosity of the blood shows a slight variation from normal.

THE MECHANISM AND SIGNIFICANCE OF THE GUM MASTIC TEST *

S. L. IMMERMAN, M.D.
Assistant Physician, Philadelphia Hospital for the Insane
PHILADELPHIA

In 1915, Emanuel[1] announced a new colloidal reaction in the spinal fluid. He used gum mastic, a reagent which was very easily prepared. Of thirty tests made in psychiatric patients, there occurred complete precipitation in all the tubes in fourteen syphilitic cases (paresis, tabes and cerebrospinal syphilis). Cutting,[2] using a slightly modified technic, examined the spinal fluid of 200 psychiatric patients. Only the syphilitic patients gave positive results, but the number of tubes in which complete precipitation occurred varied. Lowrey[3] obtained varying degrees of precipitation in twenty different paretic fluids, as well as a few positive results in nonsyphilitic patients.

The present study was undertaken to determine whether different "curves" occurred in cerebrospinal syphilis, tabes dorsalis and paresis, but owing to the apparently irregular results, was extended to determine, if possible, the mechanism of the gum mastic reaction, as well as the examination of syphilitic and nonsyphilitic spinal fluids. Cutting's technic[2] was used. Briefly it is as follows: A solution of gum mastic is suspended in alcohol and distilled water. This is the reagent. It is precipitated by 1.25 per cent. sodium chlorid, but if a small amount of potassium carbonate is added, there is no precipitate unless protein, certain salts in certain concentration, or a pathologic spinal fluid is also added. In the test, therefore, the reagent, the spinal fluid in various dilutions, and the sodium chlorid and potassium carbonate are mixed. The gum mastic reagent is a pearly translucent fluid. With pathologic spinal fluids, or other substances which alter the mastic reagent, the following changes may occur: (1) loss of translucency without any distinct precipitate; (2) varying degrees of precipitation, without any clear supernatant fluid; (3) large amount of precipitation, with partly or entirely clear supernatant fluid. In the tables, therefore, "clear" refers to a maximum amount of precipitation.

---

The following experiments were performed:

1. Various dilutions of normal blood serum in physiologic sodium chlorid solution (from 0.3 to 16 per cent. blood serum) yields at once the important fact that a given percentage of blood serum always caused the same degree of precipitation of mastic. This is shown in Table 1. For example, the fourth tube of a 10 per cent. solution of blood serum, containing 0.31 per cent. serum, gives a "clear" reaction. The third tube of a 5 per cent. solution of blood serum, containing a similar percentage of serum, gives a similar result. Moreover, an examination of this table shows that a certain optimum percentage of serum is necessary to cause a maximum precipitation ("clear"). Above this optimum amount of serum, the amount of precipitation is in inverse proportion to the amount of serum present, and below the optimum, the amount of precipitation is in direct proportion to the amount of serum present. From this it follows that, according to the amount of serum present, three types of reactions will be obtained: With large amounts of protein, the end tubes of the series will contain the most precipitate or be clear; with intermediate amounts of proteins (in which the optimum reaction usually occurs) the middle tubes will contain the most precipitate or be clear; with low amounts of proteins, the beginning tubes will contain the most precipitate or be clear. (The amount of protein must not be too large or too small to cause no precipitation.) An example follows: With 10 per cent. blood serum, Tubes 4 and 5 were clear, and Tubes 1, 2 and 3 contained precipitate but no clear supernatant fluid; with 2.5 per cent. blood serum, Tubes 2, 3 and 4 were clear, and Tubes 1 and 5 were not entirely clear; with 0.6 per cent. blood serum, Tubes 1 and 2 were clear, 3 was almost clear, and Tubes 4 and 5 contained precipitate, but no clear supernatant fluid. Sodium chlorid in solution, in amounts equal to that used in the dilutions of blood serum, caused no change in the mastic reagent.

* It will be noted that with certain optimum percentages of protein a maximum precipitate is obtained. The types of reactions therefore fall into three groups: Type 1, large quantity of protein, in which the end tubes contain the most precipitate or are clear; Type 2, intermediate quantity of protein, in which all the tubes are clear, or in which the middle tubes are clear or contain the most precipitate; Type 3, small quantity of protein, in which the beginning tubes contain the most precipitate or are clear. Ppt, precipitate; clear, maximum precipitate, with therefore clear supernatant fluid.

TABLE 2.—TYPE 1, LOWEST AMOUNT OF PROTEIN, MOST PRECIPITATE IN BEGINNING TUBES

Colloidal Gold Reaction	Diagnosis	Mastic Reaction	Globulin Percentage	Wassermann Reaction
	Blood serum, 0.3%	Tube 1, clear; 2, almost clear; decreasing precipitate in other tubes	From 0.2 to 0.6 Blood serum, 0.3%	
5555552100	Tabes dorsalis 1	None clear; decreasing precipitate toward end tubes.	Tabes dorsalis 1	Weakly positive
5555531000	Paresis 3	None clear; decreasing precipitate toward end tubes.	Paresis 3	Positive
4-4-4-2+200000	Poliomyelitis 2	None clear; decreasing precipitate toward end tubes.	Poliomyelitis 2	Negative
5-5-5-2+2-00000	Poliomyelitis 1	Tube 1, almost clear; decreasing precipitate in other tubes	Poliomyelitis 1	Weakly positive
	Blood serum, 0.6%	Tubes 1, 2, clear; 3, almost clear; decreasing precipitate in other tubes	Blood serum, 0.6%	
5555521000	Paresis 4	Tubes 1, 2, clear; decreasing precipitate in other tubes	Paresis 4	Positive
	Blood serum, 1.25%	Tubes 1, 2, 3, clear; 4, almost clear	From 0.6 to 1.6 Blood serum, 1.25%	
5555520000	Paresis 1	Tubes 1, 2, 3, clear; 4, 5, somewhat clear	Paresis 1	Positive
5555542000	Paresis 5	Tubes 1, 2, 3, 4, clear; 5, almost clear	Paresis 5	Positive

2. Spinal fluids from various pathologic sources were tested with the mastic reagent. At the same time the globulin percentage of these spinal fluids was estimated in the following manner: The protein in 0.2 c.c. of various known dilutions of blood serum was precipitated by Noguchi's butyric acid method and allowed to settle a sufficient length of time (or centrifuged). These tubes were used as standards. The amount of protein precipitated by Noguchi's method in 0.2 c.c.

of spinal fluid and allowed to settle an equal length of time as in the standard tubes was compared with the amount in the latter. This was a crude method, but the readings were satisfactory for the purposes of this study. In addition to the mastic and globulin tests, a Wassermann reaction, a colloidal gold reaction[4] and a cell count were performed on each fluid. The following fluids were tested:

(*a*) Cerebrospinal meningitis, six fluids. In these the meningococci were demonstrated; the Wassermann reaction was anticomplementary in five, and negative in the remaining fluid.

(*b*) Poliomyelitis, two fluids. These were doubtful cases; the Wassermann reaction in one case was negative, in the other weakly positive; the colloidal gold readings were atypical of poliomyelitis.

TABLE 3.—TYPE 2, INTERMEDIATE AMOUNT OF PROTEIN, MOST PRECIPITATE IN MIDDLE TUBES

Colloidal Gold Reaction	Diagnosis	Mastic Reaction	Globulin Percentage	Wassermann Reaction
	Blood serum, 2%	Tubes 2, 3, 4, clear; 1, 5, not entirely clear	From 1.6 to 2.5 Blood serum, 2%	
5555542100	Cerebrospinal syphilis 4	Tubes 2, 3, clear; 1, 4, not entirely clear	Cerebrospinal syphilis 4	Positive
5555411000	Cerebrospinal syphilis 1	Tubes 2, 3, clear; 4, not entirely clear	Cerebrospinal syphilis 1	Positive
00014-4-1000	Cerebrospinal meningitis 2	Tubes 3, 4, clear; 2, 5, not entirely clear	Cerebrospinal meningitis 2	Negative
0001244200	Cerebrospinal meningitis 7	Tubes 2, 3, 4, clear; 1, 5, not entirely clear	Cerebrospinal meningitis 7	Anticomplementary
5555541100	Paresis 2	Tube 3, clear; 2, 4, not entirely clear	Paresis 2	Positive
00013-3-1000	Cerebrospinal meningitis 5	Tubes 2, 3, clear; 1, 5, not entirely clear	Cerebrospinal meningitis 5	Anticomplementary
5555542100	Tabes dorsalis 2	Tubes 2, 3, clear; 1, 4, not entirely clear	Tabes dorsalis 2	Positive
5555542100	Paresis 7	Tubes 2, 3, clear; 1, 4, not entirely clear	Paresis 7	Positive
5555542100	Cerebrospinal syphilis 2	Tube 2, clear; 3, 4, not entirely clear	Cerebrospinal syphilis 2	Positive

TABLE 4.—TYPE 3, HIGHEST AMOUNT OF PROTEIN, MOST PRECIPITATE IN END TUBES

Colloidal Gold Reaction	Diagnosis	Mastic Reaction	Globulin Percentage	Wassermann Reaction
	Blood serum, 8%	Tubes 4, 5, clear; 3, somewhat clear	From 8 to 5 Blood serum, 8%	
	Blood serum, 5%	Tubes 3, 4, 5, clear; 2, somewhat clear	Blood serum, 5%	
0001331000	Cerebrospinal meningitis 1	Tubes 3, 4, 5, clear	Cerebrospinal meningitis 1	Anticomplementary
	Blood serum, 3.5%	Tubes 3, 4, 5, clear; 2, almost clear	From 5 to 3 Blood serum, 3.5%	
00013+3+1000	Cerebrospinal meningitis 6	Tubes 4, 5, clear; 3, almost clear	Cerebrospinal meningitis 6	Anticomplementary
0013310000	Cerebrospinal meningitis 3	Tubes 3, 4, 5, clear; 1, 2, almost clear	Cerebrospinal meningitis 3	Anticomplementary
5555541100	Paresis 6	Tubes 2, 3, 4, 5, clear; 1, almost clear	Paresis 6	Positive

(*c*) Paresis, seven fluids. The Wassermann reactions in all were positive, the colloidal gold reactions all typical.

(*d*) Tabes dorsalis, two fluids.

(*e*) Cerebrospinal syphilis, three fluids.

The Wassermann reactions in *d* and *e* were positive. In view of the colloidal gold readings in these five cases, a brief description of them is merited:

Case 1 (Tabes dorsalis 1).—The patient has been in the Philadelphia Hospital for the Insane since 1894. He is a fairly advanced though apparently nonprogressing case of tabes dorsalis.

Case 2 (Tabes dorsalis 2).—In this, a case of five years' duration, there are no symptoms of paresis.

Case 3 (Cerebrospinal syphilis 1).—Symptoms of bulbar palsy began prior to 1914, how long before 1914 cannot be said.

Case 4 (Cerebrospinal syphilis 2).—The patient is 62 years old and shows no mental loss. He has had hemiplegia of nineteen years' duration, with epileptiform convulsions of two years' duration.

Case 5 (Cerebrospinal syphilis 4).—The patient has partial optic atrophy. He had an attack of mania in 1914 followed by a lucid interval, another attack of mania in 1916 followed by a lucid interval, an attack of melancholia early in 1917, and is now somewhat maniacal.

The Achilles tendon and patellar tendon reflexes in the three cases of cerebrospinal syphilis are exaggerated. It will be noted that the spinal fluids in these five cases (tabes and cerebrospinal syphilis) yielded a typical paretic curve. It has been previously pointed out that nonparetic patients and even patients who are not likely ever to become paretic may give a paretic curve with the colloidal gold test.[5]

The results of the mastic tests are shown in Tables 2, 3 and 4. These tables show that no matter what the pathologic source of the spinal fluids, the mastic reactions depend on the amount of globulin present. As with blood serum, the type of reaction falls into three groups, according to the amount of protein present. In Table 3 it is seen that three cases of cerebrospinal syphilis, three cases of cerebrospinal meningitis, one case of tabes dorsalis, and two cases of paresis yielded similar reactions. Normal spinal fluid caused no change in the mastic reagent, or occasionally a loss of translucence in one or two tubes.

CONCLUSIONS

1. The amount of precipitation in the gum mastic reaction depends on the quantity of globulin present in the spinal fluid tested. The maximum precipitation is obtained with an optimum amount of globulin.

2. The reaction obtained does not determine whether the fluid is syphilitic or nonsyphilitic.

---

[4] I am indebted to Dr. S. F. Hogue of the Pepper Laboratory for the colloidal gold tests.

[5] Immerman, S. L.: Herpes Zoster in Tabes Dorsalis and General Paralysis of the Insane, The Journal A. M. A., June 2, 1917, pp. 1607-1609, Footnotes 16 and 17.

3. The gum mastic test is not equivalent to or supplementary to the colloidal gold reaction.
4. As a clinical test, the information obtained from the gum mastic reaction can be obtained by much simpler means.

Thirty-Fourth and Pine Streets.

BUTTER AS A VEHICLE OF INFECTION IN TYPHOID*

MARK. F. BOYD, M.D.
Epidemiologist, Iowa State Board of Health; Associate Professor of Preventive Medicine, State University of Iowa, College of Medicine
IOWA CITY, IOWA

Very little reference is made in medical literature to the possibility of the transmission of infective agents through butter. Fewer still are reports of actual dissemination of disease by this agency. Rosenau, Frost and Bryant[1] found *Bacillus coli* in six, streptococci in fourteen and the tubercle bacillus in two of twenty-five samples of market butter collected in Boston. Swithenbank and Newman[2] cite several investigations in which the tubercle bacillus was found in the butter examined. H. W. Hill[3] reports a rural outbreak of diphtheria in which the epidemiologic evidence indicated that distribution of the diphtheria bacillus had been effected through the consumption of butter from a local creamery which had been receiving cream from premises on which existed a case of diphtheria. Hill also reports[4] an outbreak of from thirty-five to forty cases of typhoid localized to one ward in Anoka. The only discoverable medium of infection was country butter, retailed at a local grocery and made at a farm during the course of an unrecognized case of typhoid.

No other reports have come to my attention in which butter has been considered the medium by which pathogenic organisms were disseminated.

Zae Northrup[5] has studied the influence of the products of lactic organisms on *Bacillus typhosus*. She finds that the minimum acidity produced by *Bacterium lactis-acidi* which will destroy the typhoid bacillus corresponds to 80° acid in milk and 28° acid in whey. *Bacterium bulgaricum* has less effect, requiring the production of 208° acid in milk or 60° acid in whey to exert the same effect. She finds that the time required for inhibition to take place is in inverse proportion to the minimum acidity producing inhibition. The influence which the other species of bacteria that may be present in milk exert on lactic fermentation prevents any very definite conclusions from being drawn from her experiments. Northrup quotes Boethel, who states that "in butter, typhoid bacteria are found after ten days, especially in butter which is strongly acid, as this enclosed sour brine is a good nourishing medium." She also states that Bassenge, as well as Behla, says that when milk, butter, etc., contain 0.4 per cent. lactic acid, typhoid bacilli are killed within twenty-four hours, although Frankel and Kister found them living even after forty-eight hours.

The meager data available prompt the reporting of the following two outbreaks, in the first of which the epidemiologic evidence implicating butter is quite conclusive, though in the second, the evidence, while suggestive, is not sufficient to be conclusive.

FIRST EPIDEMIC

Township X is located in the northeastern portion of Iowa, and is altogether rural. In 1915, it had a population of 894, including the 353 persons of the village of Y, in which is situated a creamery. In the dairy farming districts, the practice of churning in the farm home is at present quite obsolete, not being carried on even to secure the butter needed for home consumption. Table butter is secured from the creamery to which the fresh cream or whole milk is sold.

Township X has heretofore been reasonably free from typhoid fever. During August, 1917, seven cases developed between the 12th and 21st and, September 2, one additional case, in which the prodromal period was prolonged, was recognized. Two of these patients lived in the village of Y, and the remainder were scattered widely in the country. The eight cases occurred in six homes, two country homes having two cases each. The last four cases occurred so close together as to indicate simultaneous infection from the same source. Five were females, and three males. Three were between 15 and 20 years of age, two between 20 and 50, and three were over 50 years of age. The occurrence of several cases in one locality, with closely approximated dates of onset, indicates that infection had probably been contracted from a common source at approximately the same time.

None of the patients had been away from home except on trading trips to nearby towns which were free from infection. Careful and detailed inquiries failed to elicit any information concerning opportunities for the contraction of infection through contact, from food or drink consumed away from home, or from foods purchased at retail and brought into the home. The only food brought into these homes at the probable time of infection was butter produced in the local creamery at Y, and consumed by all the patients. Five of the victims were heavy consumers of fresh buttermilk from the same creamery. They were all considered the heavy butter users of their respective housholds. Twenty-nine persons, including the patients, lived in the six invaded households. In no discoverable particular had these households any common association that would account for the introduction of typhoid bacilli, excepting the butter.

Meanwhile, in a home in an adjoining township, there existed a case of typhoid in which the patient had taken to bed, July 31. From these premises cream was sold to the creamery in Y until August 23. In the early stages of the illness of this patient, proper care in the collection and disposal of the discharges from the patient was not exercised. I was informed, for instance, that undisinfected feces was permitted to stand outdoors for long periods, accessible to flies. During this time, four contact cases developed on the premises, and three other cases in the immediate neighborhood which could be ascribed only to carelessness in the disposal of infective material. After this patient had been sick about a week, a competent nurse was installed.

In the creamery at Y, the cream is not pasteurized before ripening or churning, being usually churned the day following its receipt. Although most of the butter is packed for shipment to a commission house in New York City, a small amount of fresh butter is returned to the patrons furnishing cream, and is also sold in the stores in Y.

[5] Northrup, Zae: Tech. Bull. 9, Michigan Agric. Exper. Station.

The epidemiologic evidence clearly indicates that at some time in early August, an infected lot of cream was sent from the foregoing premises to the creamery at Y. Here it was churned, and a small amount of the butter and buttermilk from that churning was distributed in X township.

SECOND EPIDEMIC

P is a thriving town in south central Iowa, having a population of 1,324 in 1915. The town and adjacent countryside is largely populated by Hollanders. In September and October, 1915, eight cases developed in P, and two in the adjacent countryside. One case had occurred during July.

Of the epidemic cases, eight patients had been out of town during the month preceding their illness, but while out of town their exposure to contact infection could not be learned. Patients 2, 6 and 9 had been to the state fair at Des Moines. Patients 3 and 10 had been in the country adjacent to P. Patient 8 had been to Oskaloosa twice, September 15 and October 14, and Patient 11 had returned from San Francisco, August 21.

The other cases, classified according to the dates on which the patients took to bed, are as follows: September 12, two cases; September 14, three cases; September 26, one case; October 3, one case; October 10, two cases; October 24, one case. It is therefore seen that the outbreak was not explosive in character, but covered an extended period of time. From these data it might appear that the cases were not due to the use for a brief period of a common active route of infection.

Of the ten patients, nine were females and one was a male. It will be further noticed that the cases were all among adults or young adults, the youngest, in Case 5, being 14 years old. This is a rather unusual distribution of cases, and the preponderance of cases in adult females is noteworthy.

Classified according to occupation, the patients are thus grouped: housewife, 10, 11 and 1; clerk, 1; telephone operator, 2; college student, 6 and 8; school girl, 5; farmer, 9; at home, 3. There is no preponderance of cases among members of any single occupation. The home sanitation of all cases developing in P was good.

Patients 1, 7 and 9 said their health previous to the attack had been poor. This might possibly indicate that infection took place somewhat earlier than would be judged from the date of taking to bed. The other patients considered their previous health good.

Contact infection seems possible only with Patient 5, who lives next door to Patient 6. No history of contact was obtainable in any of the other cases.

Three patients were sole users of the city water and four used it occasionally. These were Patients 2, 11, 6, 9, 1, 5 and 8. Three (10, 7 and 3) used water from private wells exclusively. A consideration of the distribution of the residence of these patients, the time of onset and their ages and sexes does not indicate that drinking water is responsible for the outbreak.

One patient used condensed milk, two used milk from their own cows, three denied the use of milk, and four used milk from three separate sources. It is evident that milk can be excluded as a source of infection.

Nine people had eaten ice cream at several different places: four (1, 2, 6 and 8) at W; six (2, 3, 5, 6, 7 and 8) at X; three (3, 6 and 8) at Y, and three (4, 8 and 10) at other places. Patient 9 denied the use of ice cream, and Patient 11 was uncertain. The ice cream sold at W, X and Y is manufactured at different places.

All patients had ordinarily secured their meals at home previous to their illness, but eight patients (1, 2, 6, 7, 8, 9, 10 and 11) had eaten at a church social given by the R church, August 26. Patients 1, 2 and 11 had secured meals at three different restaurants in P, and Patients 3 and 4 had eaten in the country. This church social seems to be the only possible common place of infection, but it seems remarkable, even if infection was contracted there, that Patients 1, 7 and 8 would be five and six weeks in the incubation stage of the disease. It should further be noted that Patients 1 and 7 state that their previous health had been poor, which might indicate nevertheless, that recognition of typhoid was delayed. Among other foods served at the church social were potato salad, chicken sandwiches and ice cream. Patients 1, 2, 7, 9 and 11 ate both potato salad and chicken sandwiches. Patient 8 denied eating anything besides ice cream, and Patient 10 died before the investigation. We have endeavored to find the sources from which were donated the potato salad and the chicken, but so far have been unsuccessful. The ice cream served came from Z, as did also a portion of the butter. Water was not served.

This social had a very large attendance, which was estimated as high as 500. It will thus be seen that probably a little over 1 per cent. of its patrons subsequently developed typhoid. It should be further noted that Patients 5 (contact) and 3 did not attend.

Five patients (2, 3, 4, 6 and 8) used butter from Z, at their homes, and three (1, 7 and 9) used butter from various sources, including Z, in the month preceding their illness. Patient 5 did not use Z butter.

Butter from Z is thus the only common ascertainable medium of infection for those patients who attended the church social and those who did not. The Z butter used at the church social was only one fifth of the total amount of butter used. If some article of food at the social had been the medium of infection, in view of the large attendance, we could ordinarily expect a much larger percentage of cases occurring among those who had eaten there. Furthermore, the incubation period in certain of the cases is long, if the church social is considered the place where infection was acquired. We have been unable to ascertain if the church social patients used Z butter, although it is known that this butter was served.

It was learned that on August 21, the manufacturer of Z butter had purchased thirty-nine pounds of cream from J. V., whose wife had typhoid fever in March and April, 1915. This was the second attack of typhoid which Mrs. J. V. had sustained, having experienced the first while a girl of 3 in Holland. This cream had been churned, with other cream, August 23, without pasteurization before ripening. The butter made from it could therefore have been in the local market by the date of the church social. Efforts were made to secure specimens of the feces of Mrs. J. V. for laboratory examination, but these were refused.

The possibility of transmission by means of butter is therefore the most definite evidence we were able to secure from the *second outbreak*. Those in charge of the church social were not particularly willing to furnish the desired information.

COMMENT

Milk and cream are very suitable mediums for the *multiplication* of the typhoid bacillus, particularly in the warmer months, but with the gradual increase of lactic acid in the souring or ripening, the typhoid bacilli undergo a gradual diminution in numbers. If we assume that a certain lot of sweet cream did become infected, what might we be justified in considering the subsequent chain of events? With souring, the typhoid bacilli undergo a gradual reduction in numbers. Furthermore, the infected sour cream is diluted with several times its volume of uninfected cream at the creamery. Dilution and attenuation or destruction of the infective organisms thus occurs. Furthermore, the butter made from such cream is not always immediately disposed of, but different lots may remain in storage or on the retail market for several weeks, during which time the strong salt solution in the butter may effect a further reduction of the number of typhoid bacilli present. Therefore, commercial butter would not necessarily cause an explosive outbreak of disease similar to that caused by infected milk; and, furthermore, the number of cases in proportion to the size of the infected lot of butter would be much smaller when compared with the number resulting from infected milk.

It should be noted that in neither of these instances was the cream pasteurized before ripening with a pure starter. These examples serve to indicate that pasteurization of cream for butter-making is as highly necessary from the standpoint of disease prevention as it is desirable from the standpoint of the prevention of undesirable fermentations.

TREATMENT OF SCIATICA

WITH AN ANALYSIS OF NINETY-ONE CASES *

ISRAEL STRAUSS, M.D.
NEW YORK

Sciatica, until very recently, was considered a distinct morbid entity. It was defined as a neuralgia of the sciatic nerve due to conditions within the nerve itself, or caused secondarily by organic lesions adjacent to the nerve, its roots or their origin in the cord. In the past few years, however, there has been a tendency in practically all the cases to regard the condition as secondary to some organic lesion.

Déjerine and his school have called attention to the segmentary distribution of the sensory disturbances in some cases of sciatica, and this they consider evidence that the site of the inflammation is in the roots and not in the trunk of the nerve. They have given the name of "radiculitis" to this condition. Wertheim-Salomonson asserts that one half of the cases of sciatica which he observed were due to radiculitis; he is of the opinion that most investigators overlook these cases because they fail to recognize the root type of the sensory disturbances. Many authors speak of neuralgia of the nerve, and it is probable that the indiscriminate use of this term has caused skepticism regarding the existence of sciatica as a clinical entity. A few believe with Gowers that all cases of sciatica are due to a neuritis.

It is held by others that most of the cases of idiopathic sciatica are due to lumbosacral and sacro-iliac disease and sacro-iliac subluxation. In fact, in the discussion of Rogers' paper[1] before the Section on Orthopedic Surgery at the 1916 session of the American Medical Association, some of the members went so far as to deride the idea that there could be an essential nerve inflammation. Now, while there is no question that inflammation of the sacro-iliac synchondrosis, if it is intense enough and of long duration, can cause symptoms which are indicative of irritation of the sciatic nerve or the roots entering into its formation, and although treatment of the primary condition will often remove the manifestations of sciatica, the symptoms which are caused by sacro-iliac disease are so definite that there should be no difficulty in their detection and differentiation from symptoms referable to the sciatic nerve or its roots. The same statement holds true regarding hip disease, which has been regarded by some as causative of sciatica.

As our knowledge has been obtained mainly from the appearance of the nerve when exposed at the operation for stretching, or from pieces occasionally removed at such times, little is known of the pathology of the condition. The nerve is described as being red and swollen, and marked exudation into the nerve sheath and especially into the connective tissue between the funiculi has been observed. Hemorrhages have often been found; occasionally the endoneurium is involved, and degeneration of the nerve fibers has been reported. The microscopic appearance of the nerve and even the edema may, of course, be due to the handling and exposure of the nerve during the operation. The same is true of the hemorrhages that have been found. It may very well be that the true pathologic condition responsible for this disease lies nearer the roots of the nerve, either within the vertebral canal or in parts just outside. There has been no opportunity to examine the nerve in these regions.

ANALYSIS OF CASES

My own experience has led me to believe that there exists a large group of cases in which the lesion, functional or organic, exists in the nerve itself; and in order to verify this fact, I have carefully examined ninety-one cases which have come under my care in the past years. In all these cases, definite organic lesions elsewhere could be excluded. The greater number of these patients were seen in the neurologic service of the Mount Sinai Hospital, and I am indebted to Dr. Bernard Sachs for the privilege of using this material.

The majority were between the thirtieth and sixtieth years of age; and contrary to the statistics of most authors, who give a ratio of five males to one female, the proportion of men and women was nearly equal, namely, fifty-one males and thirty-nine females.

The onset of pain was almost always gradual. The pain began in the sciatic notch or in the lower lumbar region as well, and gradually extended down the course of the sciatic nerve. In most of the cases, the pain at the beginning was not severe but rather of a dull, aching character, so that the patient paid very little attention to it. The pain was sticking, burning or lancinating in character, and radiated downward from the sciatic notch along the posterior aspect of the thigh into the calf muscles and foot. In many of the chronic cases it was confined to the calf muscles, principally on their outer aspect, and to the outer side of the foot, where it became persistent and caused as much discomfort as the pain in the thigh and buttock during the early stages.

---

* From the neurologic service of Mount Sinai Hospital.

[1] Rogers, M. H.: An Analysis of Fifty Cases of Sciatica, The Journal A. M. A., Feb. 10, 1917, p. 425.

The influence of posture on the severity of the pain varied. In the early stages the prone position was found to be more comfortable, but in the later stages walking appeared to give relief in some cases. There were no definite points of local tenderness.

In nineteen cases there was distinct paresthesia; in six there were areas of hypalgesia; and in seven, areas of hyperesthesia were found. Each patient was examined with the view of diagnosing radiculitis, but we were unable to detect definite sensory disturbances corresponding to involvement of the roots or segments of the spinal cord. It has been stated that the pain in radiculitis is intensified by coughing and sneezing, and in many of the cases this symptom was present. However, in the absence of definite segmentary disturbances it did not seem to us that the diagnosis of radiculitis was warranted. We found Lasègue's sign present in varying degrees of intensity in nearly all of the cases, and its intensity corresponded with the severity of the affection. In long standing cases the reflexes were always affected. The knee jerks were absent twice (which is very rare), diminished in intensity in twenty-two, and active in twenty cases. The Achilles tendon reflex was absent in ten and diminished in seven cases. Muscular atrophy was present in only eight cases, though very frequently the muscles of the affected leg were flabby. There were no other trophic changes.

The Wassermann reaction in the blood was negative in all of the cases. In sixteen cases, lumbar puncture revealed normal spinal fluids. Syphilis, therefore, can in all probability be excluded as a cause of sciatica. One case which improved under epidural injections yielded a spinal fluid which contained twenty-seven cells. This exceptional finding, together with the presence of bladder symptoms, changes in the abdominal reflexes and weakness in the affected leg, led me to conclude that the condition was not sciatica despite the good result obtained by treatment.

In twenty-eight cases, roentgen examination of the vertebral column and sacro-iliac joints was made. One showed a destruction of the fifth lumbar vertebra of unknown character, four showed mild spondylitic changes in the lumbar vertebrae, and two arthritic changes in the sacro-iliac joint.

The average duration of the illness was six months. The briefest period was three weeks, and the longest, twenty-seven months. In all the cases of this series, organic abnormalities outside the sciatic nerve itself were excluded, and the patient recovered without any treatment except that directed to the relief of the nerve symptoms.

TREATMENT OF SCIATICA

In a consideration of the treatment of sciatica, some attention to the question of prophylaxis is in order. The condition is undoubtedly more frequent during the summer months. This is probably due to the exposure of the body to drafts in order to sleep during hot nights. It is unquestionably true that individual susceptibility to climatic variations exists. Those in whom a draft seems to bring on an attack of coryza, or vague pains in the muscles which are commonly designated as rheumatic, ought to be especially careful not to subject the legs to such exposure. This holds true regarding the use of the cold plunge or of shower baths by such persons. Probably many cases of sciatica could be aborted in their early stages if patients and physicians would recognize the significance of the early pains and use remedial measures promptly.

In the early stages, rest in bed, the application of warmth along the course of the nerve, especially in the gluteal region, and the administration of large doses of the salicylates are indicated. Complete rest in bed is the one remedy on which stress should be laid. The rest, and moist heat in some form, are the two most efficacious measures in the beginning. All forms of massage are absolutely contraindicated. At this stage they always do harm. Counterirritants likewise are of little benefit. If salicylates are given, they should be administered in large doses.

The salicylates undoubtedly lessen the pain, and in my opinion also exert a beneficial effect on the inflammatory process itself. If the pain is severe, codein should be freely administered. If the attack does not yield to these measures, and especially in those cases which have lasted for weeks or months, recourse must be had to other methods.

There are two methods which have yielded good results: One is the injection of physiologic sodium chlorid solution into the neighborhood of the nerve according to the technic of Lange, and the other is the epidural injection along the lines described by Cathelin. In making perineural injections, the patient lies on the abdomen with a pillow underneath its lower part, and the feet projecting beyond the edge of the table or couch. A line is then drawn from the sacrococcygeal articulation to the lowest point of the postero-external border of the great trochanter. The point of puncture is 1 inch to the outer side of the junction of the inner one third and outer two thirds of the foregoing lines. A trocar and cannula about 20 cm. in length and 2 mm. in caliber is used in the injection. The point of the trocar ought not to project very far beyond the cannula. The needle is inserted directly downward through the gluteal muscles until the nerve is reached. When the nerve is touched, the patient feels a sharp, shooting pain down the leg, and there is very often involuntary contraction of the gastrocnemius muscles. When the nerve is struck, the trocar is immediately withdrawn, and a syringe attached to the cannula. Physiologic soduim chlorid solution is then injected in amounts varying from 100 to 150 c.c. Considerable pressure is sometimes necessary in order to force the fluid into the tissues, and in such cases, care must be taken that the needle is not forced into the nerve. Considerable pain may follow the injection, which, as a rule, subsides after an hour.

It may be necessary to repeat the injection every other day until at least five are given, but as a rule three injections suffice. Alcohol should never be used for these injections.

The epidural space in an adult begins at the lower edge of the first sacral vertebra, where the dura ends. It extends down to the sacrococcygeal articulation. At this level the injections are made. There are certain landmarks by which this opening, the foramen sacrale superius, may be identified. It lies at the end of the crest made by the spines of the sacrum. It has the shape of an inverted V or U, and is about 1 cm. wide and from 1.5 to 2 cm. in length. It is bordered laterally by two prominences, the cristae sacrales laterales, which are usually easily felt by the finger. The opening is covered by a dense fibrous ligament, the ligamentum sacrococcygeum. The opening lies generally 2 cm. above the end of the gluteal fold.

The needle used for the injection should be about 8 cm. in length, and 1 mm. in caliber. I have used an ordinary steel needle previously tested as to its flexibility. If greater flexibility is desired, a needle made of platinum iridium may be used; but a broken needle need cause no alarm: it will do no harm if allowed to remain in the epidural space. The needle is to be inserted to a depth of 6 cm. to reach the second sacral vertebra. There is no danger of entering the subarachnoid space, because the dura ends at about the level of the first sacral vertebra; however, to be certain that this space has not been entered, it is well to wait for a few minutes before injecting to see whether there is an escape of cerebrospinal fluid. If possible, when inserting the needle, one should place the patient in the knee-chest position in order more easily to locate the landmarks. If the injection is made with the patient lying on the side with the knees and thighs flexed, the landmarks are not so easily discerned, and the gluteal fold usually lies above the foramen. It may be difficult, if not impossible, to enter the epidural space of very stout persons, especially of stout women. In such cases, recourse must be had to the nerve injection.

It has been my custom to anesthetize the skin and tissue overlying the foramen and the ligament with novocain. In doing this, one must be careful not to cause much swelling, which might obliterate the landmarks. After the needle has been pushed through the skin, considerable resistance is met at the ligament. Once this resistance is overcome, the needle glides into the epidural space. If the patient is in the knee-chest posture, the needle is inserted into the body at an angle of 45 degrees. After it has passed through the ligament the needle is held so that it is horizontal to the body. During the injection, the patient lies on the affected side.

The injection consists of warm sterile physiologic sodium chlorid solution. To the first 10 or 20 c.c. of solution is added 0.125 gm. of novocain with epinephrin, and a few minutes are allowed to elapse after their injection to obtain the full benefit of their anesthetic effect. In all, from 60 to 80 c.c. of solution are injected at a time.

The injections are given at forty-eight hour intervals. They may be given in the office, and the patient will have no difficulty in going home. It is preferable, however, for the patient to remain in bed during the intervals. The average number of injections required is three. Occasionally it may be necessary to give five, but sometimes two or even one suffice to relieve the condition. The most difficult cases to cure are the chronic ones in which the pain is along the outer aspect of the thigh. In some instances this pain persists even after several injections, and then treating the limb with superheated air in the Tyrnauer apparatus is efficacious. The heat treatment alone in the subacute and chronic cases is of no avail. Massage ought never to be used—it appears to do more harm than good. A patient may improve after several epidural injections but not be entirely cured. The injections of sodium chlorid solution along the course of the nerve in the gluteal region may cause the disappearance of the pain. There have been no untoward results from the epidural injections. The knee jerk on the affected side has disappeared for a short time, and sometimes the patient complains of delayed micturition; but these symptoms soon disappear.

The treatment of sciatica by injection of sodium chlorid solution, whether epidurally or in the neighborhood of the nerve, offers a means of shortening the duration of this painful malady from weeks and months to days.

Clinical Notes, Suggestions, and New Instruments

THE STERILIZATION OF SURGEONS' SANITARY PAPER CAPS*

Wallace A. Manheimer, Ph.D., New York

Paper caps in place of linen caps for surgeons are becoming very popular for a number of reasons. They are cheap, costing less than the laundering and depreciation of linen caps, are cool and light, are automatically adjustable and are free from lint. While there are probably several types of paper hats on the market, the one which has an elastic crape paper insertion in the back is the one to be recommended because it adheres firmly to the head, preventing the dropping of dust on the wound. This hat is made over a block the shape of the head by pasting a paper band of glacine paper to a crown piece composed of any type of paper. In the back of the paper band is an elastic insert composed of crape paper which permits the hat to be stretched sufficiently to conform to heads of any size. A piece of thick corrugated absorbent paper is pasted on the inside of the paper band just where the hat touches the forehead, in order to absorb sweat. These hats make a neat appearance and have proved satisfactory.

The practice of sterilizing surgeons' caps varies considerably throughout the country, most of the leading hospitals dispensing with the practice altogether. Nevertheless, a great many surgeons require sterilized hats, and for this reason the methods which can be used for the sterilization of the paper cap are set forth below. The hat is made of a glacine paper which has high tensile strength, but must be handled carefully during sterilization.

METHODS OF STERILIZATION

1. *Hot Air Sterilization.*—At temperatures ranging from 120 to 160 C., hot air is not satisfactory for the sterilization of glacine paper, of which the hat is made. The paper becomes hard and brittle, and cannot be handled without tearing.

2. *Autoclave Sterilization.*—(*a*) At 15 to 16 pounds steam pressure for thirty minutes, the *Bacillus subtilis* spores on the threads packed in the hats are destroyed, the paper is browned, and the tensile strength and friability of the paper is only slightly impaired. No dry heat is used.

(*b*) With 15 to 16 pounds steam pressure for fifteen minutes, 10 inches of mercury vacuum with preliminary heating for fifteen minutes, the hats are sterile, slightly browned. *B. subtilis* spores are destroyed and the strength of the hat is unimpaired.

(*c*) With 10 pounds steam pressure for fifteen minutes, and a rapid release of steam, three minutes, the hats dry on removal, the color being only slightly changed. The hats are sterile, *B. subtilis* spores are destroyed, and the tensile strength of the paper is unimpaired.

3. *Flowing Steam Forty-Five Minutes in the Arnold Sterilizer.*—The hats are dried for two minutes in a hot air oven. The tensile strength is unimpaired, the hats are slightly browned, they are sterile and *B. subtilis* spores are destroyed.

CONCLUSIONS

1. Paper caps in place of linen caps used by surgeons can be sterilized, if desired, in a number of ways, but not by dry heat, which destroys the tensile strength of glacine paper.

---

* From the Research Laboratory, New York Department of Health.

2. The hats can stand the autoclave up to 15 pounds pressure for fifteen minutes without appreciable impairment of strength. The best method to use is low pressure (10 pounds) for fifteen minutes with rapid release of steam from the sterilizer, for the purpose of drying the hats.

3. Flowing steam for forty-five minutes, with two or three minutes in the hot air oven, sterilizes the hat (destroys *B. subtilis* spores) without impairment of the paper.

FRACTURE REDUCTION WITH THE AID OF A SIMPLE TRACTION APPARATUS

Robert Soutter, M.D., Boston
Assistant Surgeon, Children's Hospital, Boston; Instructor, Harvard University Medical School

This apparatus occupies a space of 24 by 4 inches. It is convenient, therefore, for emergency fracture work at the front, or in hospitals in which a fracture table is not available. It is also applicable for the open reduction of fractures, for bone graft operations, and for plating, wiring or banding. It can be used for fractures of the shoulder, the shaft of the humerus, the elbow, the forearm, the wrist, the hip, the shaft of the femur, the knee, the tibia or fibula or both.

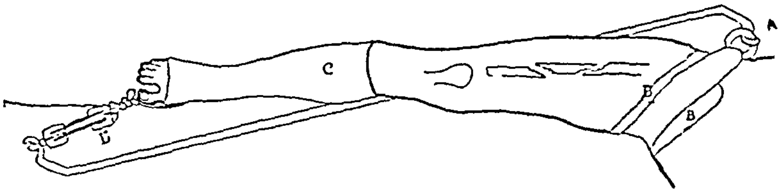

Fig. 1.—Fracture of the femur: Portable traction rod with two double block pulleys, and leather legging, *C*, applied. The rod is hooked into an iron ring at *A*. A heavy double canvas belt 4 inches broad is passed around the thigh over a folded sheet, *B*. The belt passes through the iron ring at *A*. Instead of the legging, *C*, a three strand army webbing may be passed around the ankle as shown in Figures 2 and 3. The ankle is well padded before the webbing is applied.

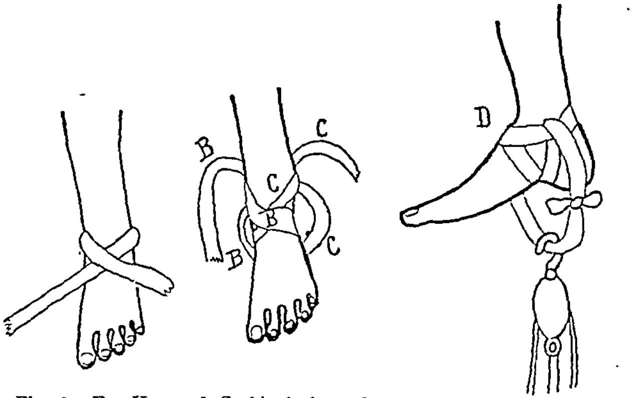

Fig. 2.—Dr. Hayward Cushing's knot for temporary traction during operations on the leg. The ankle is well padded with heavy felt passed around under the webbing. *The webbing is crossed in front of the foot.* The end *B* and the end *C* may be traced in the illustration. On the outside of the ankle, the end *C* crosses in front to the inside under the foot, then upward on the outside, and is looped around the original outside piece.

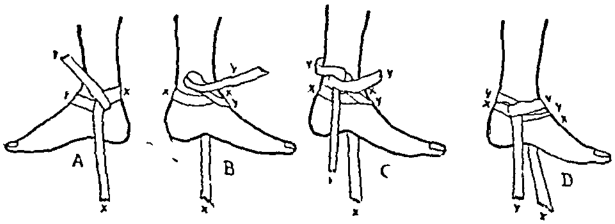

Fig. 3.—Knot used by Dr. Hawley for temporary traction on the leg. The webbing should be triple or double. It may be traced by the accompanying drawings. *A heavy felt pad should be put around under the webbing.*

The control of the traction is simple; it need not be removed for open operation or for the application of the dressing, splints or plaster.

Traction is applied by means of two double or triple block pulleys; one pulley is hooked to the rod, and the other to the ankle for traction on the leg. Countertraction is applied at the hip by a broad canvas belt over a folded sheet (for padding). The belt goes through a large iron ring which hooks over the traction rod.

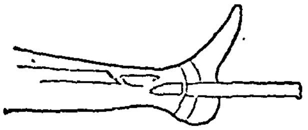

Fig. 4.—Fracture of the lower leg: Method of applying tape to the ankle, using Cushing knot (see Fig. 2).

For traction above the elbow, an army webbing strap doubled is passed over a folded pillow case (for padding) around the forearm, flexed at right angles, or a heavy pad is placed around the wrist and the webbing attached over it by one of the knots shown in the accompanying illustrations. The webbing is hooked to one pulley, and the other pulley is hooked to the rod. Countertraction is applied to the other end of the rod by means of a canvas belt passed around the chest high under the arms. The canvas belt passes through a heavy ring. The rod is hooked to this ring (Figs. 1, 2, 3, 4, 5, 6, 7 and 8). It is important to pad the webbing. The countertraction at the hip should be well padded to avoid injury to the sciatic nerve. A slip noose should not be used on the arm or leg. Several knots are suggested in connection with this method of reducing fractures; one devised by Hayward W. Cushing, and another used by Dr. Hawley.

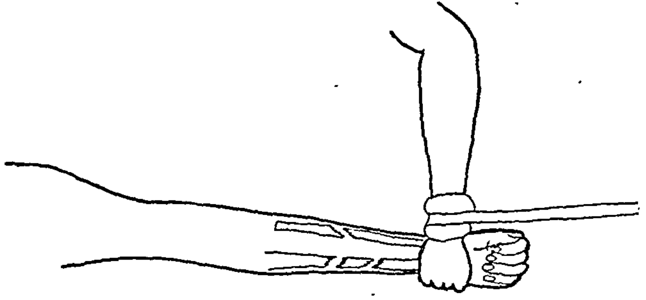

Fig. 5.—Fracture of the forearm: Traction applied to the assistant's wrist.

For open operation on the arm or forearm, the rod is placed on the operating table, a pillow over it, and the patient lies on the pillow. The exposed rod is covered with a sterile sheet allowed to hang over it. Sterile webbing is used, and a sterile pillow case folded for a wrist or a forearm pad. The pulleys and the tape are covered with sterile sheets. When the leg is prepared for operation, the rod may be covered by sterile sheets. The traction is controlled by a nonsterile assistant.

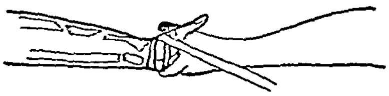

Fig. 6.—Fracture of the forearm: A pad is placed about the wrist, and the knot described in Figure 3 is applied to the wrist. This knot distributes the pressure and prevents constriction. The operator or an assistant controls the hand while traction is being made.

This apparatus is part of a larger portable traction apparatus used by me for over twelve years.[1] The apparatus consists of a rod, 8 feet long, with an offset and hook at each end. The rod is strong and jointed to make it portable.

---

[1] Soutter, Robert: Boston Med. and Surg. Jour., 1907, 157, 724-726; Operations on Bones, Joints, Muscles and Tendons, Ed. 1, New York, the Macmillan Company, 1917, pp. 35, 227, 229.

In a large hospital, a fracture table, such as Dr. Hawley's, leaves little to be desired.

For the satisfactory treatment of fractures, a portable traction apparatus is often necessary. The apparatus described in this article has proved of great value for use in reducing fractures, and for open operations on fractures. Its size makes it especially serviceable for emergency use.

133 Newbury Street.

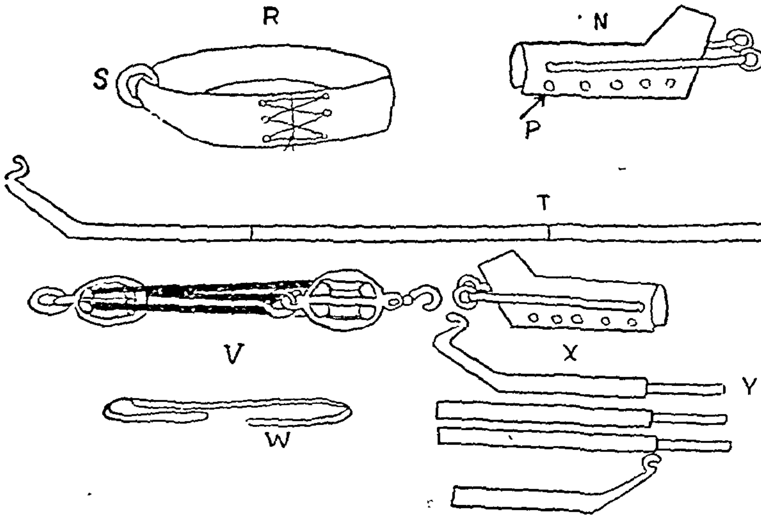

Fig. 7.—Details of apparatus: *N*, leather legging; *P*, loose rings for lacing; *R*, heavy canvas belt 4 inches broad, cross stitched with loose rings for lacing. The belt passes through an iron ring; *S*, iron ring; *T*, traction rod made from tubing; each section is 22 inches long, and there are four sections. Three iron rods 22 inches long are passed inside this tubing, and unites them into one long firm rod. *X* represents the tubing disjointed and the rods protruding; the rods may be removed for packing. *V*, double block pulley 4 inches each; *W*, webbing for ankle knot, as illustrated in Figures 2 and 3; *X*, traction rod *T* disjointed, showing how the rod *Y* may be removed from the tubing.

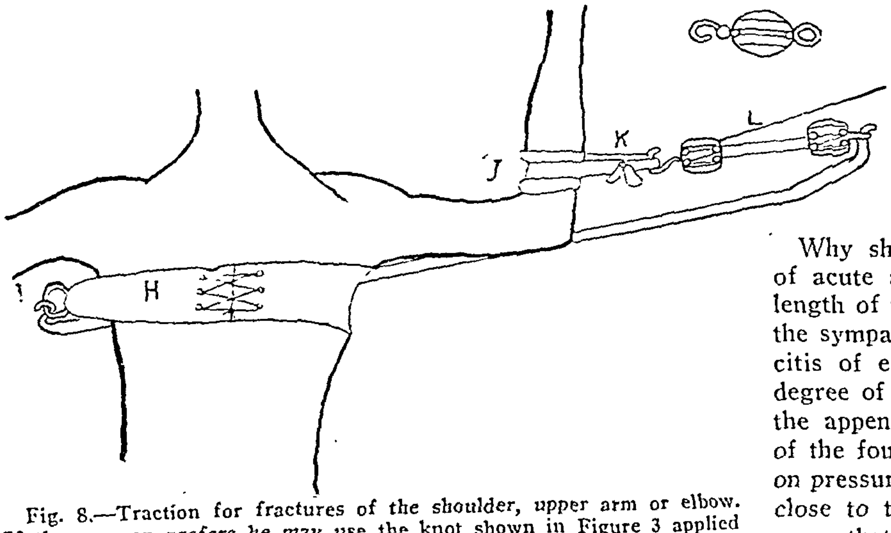

Fig. 8.—Traction for fractures of the shoulder, upper arm or elbow. If the surgeon prefers he may use the knot shown in Figure 3 applied to the wrist. The rod hooks into an iron ring at *I*; *H*, canvas belt passed through an iron ring at *I*; *J*, folded pillow case over which is passed a double army webbing *K*; *K*, army webbing hooked to pully; *L*, two double block pulleys.

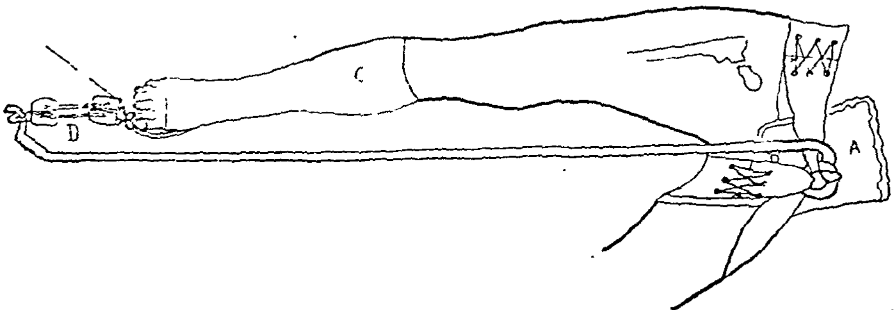

Fig. 9.—Apparatus adjusted for treatment of fractures of the femur high up. The canvas belt is applied to the other leg, and a second belt looped around the thigh portion of the first belt behind and brought around the flank double and passed through the iron ring, and then laced to itself. A piece of leather or heavy canvas is placed under the ring at *A*.

APPENDICITIS AND THE GYNECOLOGIST

Robert T. Morris, M.D., New York

About an inch and a half to the right of the navel and a trifle caudad, one will find on deep pressure a hypersensitive point in cases of chronic appendicitis of one of the four chief kinds. This tender point does not belong to cases of acute appendicitis. It does not belong to cases of pelvic irritation or infection, except in company with a similar tender point to the left of the navel. This tender point to the right of the navel will serve to give differential diagnosis between cases of chronic appendicitis and various pelvic irritations or infections.

Why does not this tender point to the right of the navel belong to acute appendicitis? Why does it not belong to right-side pelvic disturbances? In order to answer these questions, we must inquire into the nature of the tender point. *At that site we shall find* the right lumbar sympathetic ganglion. On the left side of the navel we find the left sympathetic lumbar ganglion. Apparently these ganglions represent the sensitive points. There is no direct nerve connection between the appendix and the right sympathetic lumbar ganglion. How, then, are we to acount for the tenderness on pressure? This problem introduces the question of sensorimotor synapse. Head has marked out areas of skin irritation belonging to certain organs, following the studies of Ross and of Sherrington, who showed that irritated internal organs frequently send impulses to superficial areas of the body. I postulate that the irritated appendix sends an efferent impulse to a segment of the spinal cord, and from that segment of the spinal cord an efferent impulse goes out to the skin over the area described by Head as belonging to the appendix. At the same time, a similar impulse goes out to the right sympathetic lumbar ganglion and stops there. This, at least, is my assumption. It is offered in explanation for the fact that when we have chronic irritation of the appendix there is also a disturbance of the skin in the Head zone for the appendix, and also a disturbance of the right sympathetic lumbar ganglion, which remains hypersensitive and tender on pressure.

Why should not this ganglion be hypersensitive in cases of acute appendicitis, as a rule? I assume that a certain length of time is required for the nagging appendix to excite the sympathetic lumbar ganglion. In cases of acute appendicitis of either one of the two common forms, the greater degree of sensitiveness is at McBurney's point, directly over the appendix. In cases of chronic appendicitis of any one of the four common kinds, the greatest degree of tenderness on pressure is at the point 1½ inches to the right of the navel, close to the spinal column, and corresponding to the right sympathetic lumbar ganglion. The reason this ganglion is not hypersensitive alone, but only in company with its left neighbor in cases of pelvic disturbance, is that the crossed action of the sympathetic and autonomic nerve branches between the pelvic ganglions and the lumbar ganglions causes irritative impulses to be shot simultaneously into the lumbar ganglions of the two sides.

In cases of chronic appendicitis, the second feature of diagnosis which does not belong to cases of acute appendicitis, and which does not belong to cases of pelvic disturbance, is persistent distention of the ascending colon with gas. Why should the ascending colon be distended with gas in cases of chronic appendicitis? We may assume that irritation from the nerve elements of a chronically inflamed appendix at first overstimulates the innervation of the muscularis of the ascending colon. This overstimulation, carried on for weeks or for months, eventually tires out the innervation of the ascending colon. When the innervation becomes wearied, the muscular coat of the ascending colon becomes relaxed and distended with gas, which it fails to press onward because of comparative lack of energy. This distention of the ascending colon with gas, which belongs particularly to chronic appendicitis, I call the "cider barrel sign." If we percuss the left side of the abdomen in a case of chronic appendicitis, we shall obtain a normal resonance note suggesting percussion of the cider barrel in October. If we percuss the right side of the abdomen, we obtain a percussion note suggesting that of the cider barrel in January.

These two points, then, the "cider barrel sign" and the point of tenderness on pressure to the right of the navel, appear to be important in distinguishing between chronic appendicitis and pelvic disorders of the sort that interest the gynecologist.

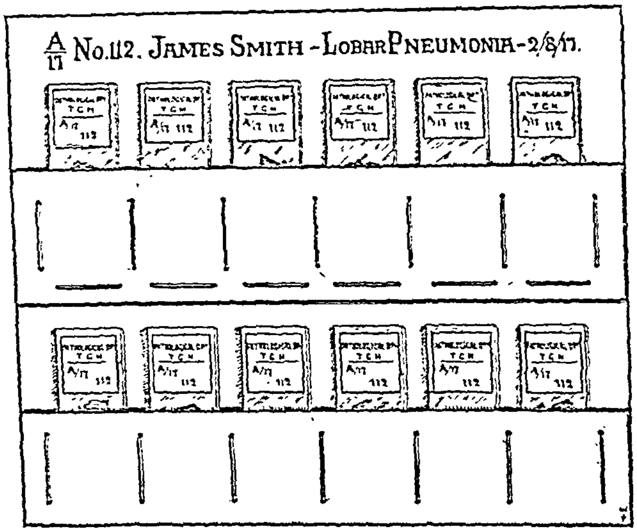
A METHOD FOR FILING NECROPSY SECTIONS

W. L. Robinson, B.A., M.B., Toronto
Department of Pathology, Toronto General Hospital

The ordinary methods of storing microscopic slides of necropsy sections in drawers or in boxes has always seemed to me not only an awkward method, but one which renders the sections very inaccessible. I wish, therefore, to submit the following means of adapting the ordinary filing cabinet to the filing of microscopic specimens of necropsy *sections* in a convenient and readily accessible form.



Adaptation of the ordinary filing cabinet to the filing of microscopic specimens of necropsy sections.

Our filing cabinet takes a card 9¼ by 7½ inches. One of the local publishing houses furnished *us with* folders of this size. The paper used is 140 pound tag manilla, cut *to a* size 9¼ inches square. One margin is then turned over *for* a distance of 1¾ inches, and wire staples eleven-sixteenths of an inch long put in so as to divide the folded strip into six equal compartments. In this way a folder which is 9¼ inches wide by 7½ inches high is made. A strip of the same material 1¾ inches wide, and of the same length as the width of the folder, is stapled in position so that the lower border is 3¾ inches above the folded lower border of the folder. This strip not only has the seven staples which divide it off into equal compartments, but also a staple at the lower part of each *compartment, thus* making space for the filing of twelve sections, and leaving room at the top for the number, name, date, and also a description of the principal pathologic lesion that has been revealed by the necropsy. There is sufficient room on the back of the folder for writing the complete anatomic diagnosis.

These folders are filed away in rotation, and can be cross indexed according to name and pathologic lesion. A cabinet 22 inches deep will hold *about* 250 of these folders when filled with microscopic slides.

Military Medicine and Surgery

INDUSTRIAL POISONING IN AIRCRAFT MANUFACTURE

ALICE HAMILTON, M.D.
CHICAGO

In the latter part of 1914, Jungfer[1] reported a new industrial disease that had appeared during the preceding year in an aeroplane factory in Johannisthal and had affected four out of a force of eight men. These men were employed in painting and spraying a solution of cellulose acetate over the linen that covers the aeroplane. All of them developed a severe acute hepatitis, and one died. Later in another factory in the same place ten men were poisoned and one died. Grimm,[2] writing shortly after, was able to give details of fifteen cases of poisoning among aircraft employees engaged in such work. The solutions used were sent to the pharmacologic institute of the University of Berlin for analysis by Heffter and Joachimoglu,[3] who reported that the toxic constituent was tetrachlorethane, of which some specimens contained as much as eighty-four in a hundred parts. They experimented on dogs, rubbing the solutions into the skin and also exposing the animals to the fumes. From the commercial mixtures and from pure tetrachlorethane they obtained the same results, namely, loss of weight, vomiting, presence of bile and blood in the urine, death with fatty degeneration of the liver, and hemorrhages into serous and mucous surfaces and in the heart muscle. In inhalation experiments narcosis came on, but was slower in appearance and less deep and lasting as the days went on, showing a gradually increasing tolerance on the part of the animals. The symptoms described above, however, put in their appearance and the course of the poisoning was the same, no matter how the compound was administered.

Tetrachlorethane had already been tested by Lehmann[4] of Wurzburg, the authority on industrial gases and vapors. As always, his experiments were for the purpose of determining the *minimum* dangerous amount of the vapor in air, and he found that air containing no more than 1 or 2 mg. of tetrachlorethane to a liter could be breathed for a relatively long period—six or seven hours a day for eighteen days spaced over four weeks—with no more serious *result than* loss of weight and drowsiness. If the fumes were stronger, narcosis came on, and after repeated exposures, serious disturbances of metabolism. In fatal poisoning he found solution of red corpuscles, basophilia, fatty liver, the heart muscle yellowish and the kidneys congested. He *found it* the most poisonous of the chlorin derivatives of the hydrocarbons, four *times* as poisonous as chloroform and nine *times* as *much* so as tetrachlormethane (carbon tetrachlorid).

The fatty degeneration of the liver as found by these German experimenters is more marked than that produced by any known substance except phosphorus, and as in phosphorus poisoning, it is associated with a yellow, flabby heart muscle, and with acute degenerative

APPENDICITIS AND THE GYNECOLOGIST

Robert T. Morris, M.D., New York

About an inch and a half to the right of the navel and a trifle caudad, one will find on deep pressure a hypersensitive point in cases of chronic appendicitis of one of the four chief kinds. This tender point does not belong to cases of acute appendicitis. It does not belong to cases of pelvic irritation or infection, except in company with a similar tender point to the left of the navel. This tender point to the right of the navel will serve to give differential diagnosis between cases of chronic appendicitis and various pelvic irritations or infections.

Why does not this tender point to the right of the navel belong to acute appendicitis? Why does it not belong to right-side pelvic disturbances? In order to answer these questions, we must inquire into the nature of the tender point. At that site we shall find the right lumbar sympathetic ganglion. On the left side of the navel we find the left sympathetic lumbar ganglion. Apparently these ganglions represent the sensitive points. There is no direct nerve connection between the appendix and the right sympathetic lumbar ganglion. How, then, are we to acount for the tenderness on pressure? This problem introduces the question of sensorimotor synapse. Head has marked out areas of skin irritation belonging to certain organs, following the studies of Ross and of Sherrington, who showed that irritated internal organs frequently send impulses to superficial areas of the body. I postulate that the irritated appendix sends an efferent impulse to a segment of the spinal cord, and from that segment of the spinal cord an efferent impulse goes out to the skin over the area described by Head as belonging to the appendix. At the same time, a similar impulse goes out to the right sympathetic lumbar ganglion and stops there. This, at least, is my assumption. It is offered in explanation for the fact that when we have chronic irritation of the appendix there is also a disturbance of the skin in the Head zone for the appendix, and also a disturbance of the right sympathetic lumbar ganglion, which remains hypersensitive and tender on pressure.

Why should not this ganglion be hypersensitive in cases of acute appendicitis, as a rule? I assume that a certain length of time is required for the nagging appendix to excite the sympathetic lumbar ganglion. In cases of acute appendicitis of either one of the two common forms, the greater degree of sensitiveness is at McBurney's point, directly over the appendix. In cases of chronic appendicitis of any one of the four common kinds, the greatest degree of tenderness on pressure is at the point 1½ inches to the right of the navel, close to the spinal column, and corresponding to the right sympathetic lumbar ganglion. The reason this ganglion is not hypersensitive alone, but only in company with its left neighbor in cases of pelvic disturbance, is that the crossed action of the sympathetic and autonomic nerve branches between the pelvic ganglions and the lumbar ganglions causes irritative impulses to be shot simultaneously into the lumbar ganglions of the two sides.

In cases of chronic appendicitis, the second feature of diagnosis which does not belong to cases of acute appendicitis, and which does not belong to cases of pelvic disturbance, is persistent distention of the ascending colon with gas. Why should the ascending colon be distended with gas in cases of chronic appendicitis? We may assume that irritation from the nerve elements of a chronically inflamed appendix at first overstimulates the innervation of the muscularis of the ascending colon. This overstimulation, carried on for weeks or for months, eventually tires out the innervation of the ascending colon. When the innervation becomes wearied, the muscular coat of the ascending colon becomes relaxed and distended with gas, which it fails to press onward because of comparative lack of energy. This distention of the ascending colon with gas, changes in the kidney epithelium. It also resembles delayed chloroform poisoning with its hematogenous jaundice. Tetrachlorethane is seven times as hemolytic for mammalian blood as is chloroform.

POISONING ABROAD

The first case of tetrachlorethane poisoning reported from England was in October, 1914, when a man died of acute jaundice after working in an aeroplane factory in Hendon. He had worked eleven weeks when jaundice developed, and he died after three weeks' illness. The liver was shrunken and green. Legge, chief medical inspector of factories, went there to investigate, and found that the man had been applying to aeroplanes what is called in English and American factories "dope." On examining the other dopers, Legge found ten with evidence of inflammation of the liver. They had worked from three to sixteen weeks before they were taken sick. All had gastric symptoms and jaundice. The next three deaths from what was now called "dope poisoning" were in women, two girls under 20 and a woman over 30. By February, 1916, the Home Office had had reports of forty-three cases, with seven deaths, five in women. The amount of tetrachlorethane in the dopes varied, but British factory inspectors considered even 10 per cent. dangerous.

The dopes were subjected to analysis and animal tests by Wilcox,[5] who also examined the organs of some of the victims of dope poisoning. His results were exactly the same as those of the Germans. Though the English dopes contained benzene, methyl alcohol and acetone as well as tetrachlorethane, Wilcox proved that the last was the cause of dope poisoning. He described, as the distinctive features of this form of hematogenous jaundice in man, a slow, insidious onset; long duration of the disease after the onset of jaundice, longer than in acute yellow atrophy of the liver; absence of marked fever, which distinguishes it from infectious jaundice, Weil's disease; and absence of the degree of anemia that would be found in arsenical jaundice. The jaundice is deeper than that of delayed chloroform poisoning.

The last paper on the subject of dope poisoning in Germany appeared early in 1915. Koelsch,[6] a Landesgewerbearzt of Bavaria, made a study of industrial poisoning from tetrachlorethane, and divided the cases into two classes: (*a*) those with pronounced gastro-intestinal symptoms, nausea, vomiting, cramplike pain, enlarged liver and jaundice; and (*b*) those with slight or no abdominal disturbance, but with various nervous symptoms, headache, paresthesias, tremors of the hands, disordered reflexes and slight paralyses. Two cases belonging to the first group had been diagnosed as lead colic, though there had been no exposure to lead. Other symptoms noted by Koelsch were increased craving for food coincident with loss of weight, and great drowsiness, persisting all of the working hours.

After this, reports from Germany ceased to come, and we have no way of knowing whether or not the advice of the factory inspectors was followed and tetrachlorethane dope forbidden. In England this has been virtually effected. Toxic jaundice from aeroplane dope was made a reportable disease in February, 1916, and brought under the workmen's compensation act. By August, 1916, the Home Office was able to state that dopes free from tetrachlorethane were now obtainable and approved by the War Office and Admiralty. Letters from Sir Thomas Oliver and Dr. T. M. Legge, written in January of this year, assured me that tetrachlorethane dopes were no longer used in British aeroplane manufacture.

THE SITUATION IN THIS COUNTRY

That is the history of dope poisoning in the older countries. In our country, despite the fact that since the war our aeroplane manufacture has increased rapidly, no case of dope poisoning has come to public knowledge. The Bureau of Labor Statistics, knowing the serious trouble that England had experienced, and wishing if possible to forestall it here, asked me to make an investigation of our aeroplane works during the spring and summer of this year. At that time the output of these factories was largely training planes, not war planes. I visited eighteen factories, in the Middle West, Florida, New York State, New England and northern New Jersey. Everything was in a state of experiment and of rapid expansion. Many of the plants were small, temporary structures, and all the doping was done outdoors. Others had doping sheds, open to all the winds. Few were large enough to employ more than one man in doping, and even he would not spend all his time at the work. It was easy to see why, even with the dangerous tetrachlorethane dope, which was still in use in some plants and had been used in several more, no case of toxic jaundice had developed. The exposure had not been long enough or severe enough. Dopers are a shifting body of men. Of fifty-three men interviewed, more than half had worked less than three months.

All these features, however, were already changing. The new factories had doping rooms and were preparing for work on a large scale. It was evident that in the future many more dopers would be employed, and that they would work continuously and in an atmosphere full of dope fumes from the drying wings. The men in charge told me that they knew doping was attended with danger, but for the most part they did not know which were the dangerous compounds in the dope or which variety was the more dangerous. I felt convinced that with conditions as they were in some of the new factories, this winter would see several cases of dope poisoning if tetrachlorethane dopes were to be used; for instead of installing down-draft suction to remove the heavy fumes, several managers were trusting to window ventilation only.[7]

Though I did not find evidence of toxic jaundice among dopers, men who worked with tetrachlorethane dopes had felt the effects of the fumes somewhat. Drowsiness was oftenest complained of, most troublesome early in the morning, and passing off as the day wore on; worse after a holiday, as if the immunity acquired had been lost, and much worse in hot, heavy weather. Some men said they were even sleepier after leaving work than while in the fumes.

There were instances of men being actually overcome by the dope fumes, but these were under exceptional circumstances, such as very hot weather and an unusual rush of work; or the doping was carried on in a greenhouse with the sun beating on the glass roof; or the hemorrhages are due to this secondary infection, and are to be regarded not as scorbutic, but rather as focal complications. Other hemorrhages are truly scorbutic. Scurvy, however, is essentially a disorder characterized by malnutrition and not by hemorrhage, taking months to develop and, from a clinical point of view, frequently latent or subacute.

---

[5] Wilcox: Lancet, London, 1915, **1**, 544.

[6] Koelsch: München. med. Wchnschr., 1915, **62**, 1567.

[7] An investigation of aeroplane factories in New York State was undertaken by the State Industrial Commission and entrusted to Drs. Lester Roos and Rosalie Bell. They found one man using tetrachlorethane who showed a slight jaundice, but whose symptoms were chiefly nervous: dizziness, sleepiness, and attacks like alcoholic intoxication.

Where is the much abused pasteurized milk left in this analysis? According to Hess, faulty diet is only one of several factors in the pathogenesis of infantile scurvy. Pasteurized milk, he states, was found to be a contributing cause if it was not fresh — if given from twenty-four to forty-eight hours after pasteurization. From this point of view, he argues, milk pasteurized in the city is preferable to milk pasteurized at the creamery, which reaches the consumer much longer after the heating process. Aging seems to play a greater part in the production of scurvy than heating, whether the milk was pasteurized or raised to the boiling point. It was found that even raw milk on aging loses its antiscorbutic properties.

One may well ask, in the light of what is now being written, whether scurvy is, after all, a distinct entity. Where vague dietary factors and equally indefinable bacterial perturbations in the alimentary tract vie with each other in the genesis of a syndrome, the open mind represents a safe attitude until more definite conclusions can be agreed on.

TRINITROTOLUENE (T. N. T.) POISONING AMONG MUNITION WORKERS

War is a grim teacher; and he must be unobservant indeed, who fails to note the numerous facts of profound scientific importance which its concomitants and consequences have instilled into the mind. This is true in the domain of disease quite as well as in other fields in which science holds sway. For the physician, gaseous chlorin had only the remotest interest at the period when the war broke out. Today poisoning with the gases used like chlorin in warfare offers a serious problem to those entrusted with the management of "gassed" victims.

Not only the actual performances on the field of battle but also the diverse preparatory processes that make possible warfare of the ultramodern sort harbor hitherto unsuspected or underestimated menaces to human health. To take proper cognizance of them means not only to prolong life and alleviate suffering in hundreds of instances, but also to promote efficiency in preparation for the strife by suitable prophylactic or other sanitary measures. Munition workers have come to be a most important element in the struggle to win. Their health has been a source of solicitude in all of the countries concerned; and in the United States, where the difficulties to be encountered are somewhat more recent, we must try earnestly to profit by the experience of those who entered the conflict earlier. Today the possible necessity of protective measures against exposure to lead, tetrachlorethane, nitrous fumes, trinitrotoluene, tetryl (tetranitromethylanilin), fulminate of mercury and certain lubricating and cooling fluids (petroleum products) used with metal products has emerged into distinct prominence.

Early in the war we called attention[1] to the serious and novel danger attending the use of tetrachlorethane as an ingredient of the varnish used to cover the wings of aeroplanes. At least seventy cases of jaundice with several deaths were reported in Great Britain before a substitute for this solvent was introduced into use. The history of the experience with the solvents or "dopes" used in aircraft manufacture has been related by Dr. Alice Hamilton[2] in this issue of The Journal. A new device calling for new modes of production under great stress has suddenly brought to light novel industrial dangers. Far more conspicuous is the problem of poisoning with trinitrotoluene — the T. N. T. of the army and navy vocabulary — which has likewise attained an enormous importance in munitions manufacture.

One commentator has remarked that trinitrotoluene shows itself a splendid antagonist in the resourcefulness of its attack and the variety of symptoms produced. A cardinal symptom is toxic jaundice, which may appear quite suddenly in munition workers or may show such premonitory symptoms as drowsiness, dizziness, depression and dark urine. Dermatitis due to the local action of the explosive sometimes occurs. A toxic gastritis is a far more important symptom. This gastric catarrh makes up part of the so-called minor illness attributable to trinitrotoluene. A discussion of this important subject before the Sections of Medicine, Pathology and Epidemiology of the Royal Society of Medicine in London[3] brought out the fact that the other minor illnesses due to trinitrotoluene are probably thirty times more frequent than jaundice; and as many thousands of workers are employed in the handling of trinitrotoluene, the problems of its toxic effects are of the greatest importance in preventive medicine and the production of munitions for the successful prosecution of the war.

Since trinitrotoluene liberates fumes at a temperature as low as 32 C. (89.6 F.), it has been argued that the poison enters the body by inhalation of nitrous fumes, on the circumstantial evidence that the incidence of its toxic effects varies with the ventilation of the factories. When the circulation of air is defective, and fumes are given off by molten trinitrotoluene, the toxic effects become more frequent, whereas good ventilation is accompanied by freedom from illness. Moore's recent analytic and experimental investigations appear to prove that the skin is the main channel of absorption of trinitrotoluene, and he insists that inhalation of its fumes or of its dust does not play any part. There is some evidence that an oily condition of the hands, such as may result from handling silk bags saturated with petrolatum, favors absorption. Personal susceptibility has some influence in determining the incidence of symptoms, and whether they appear after a short or after a considerable period of work. This is well shown in the case of dermatitis. But the amount of the exposure, or in other words the dose of the poison, is the more important factor in producing the toxic effects.

[3] The Origin, Symptoms, Pathology, Treatment and Prophylaxis of Toxic Jaundice Observed in Munition Workers, Being a Discussion by the Sections of Medicine, Pathology and Epidemiology of the Royal Society of Medicine (January, 1917), London, Longmans, Green & Co.

Surgeon-General Rolleston[3] has pointed out that the pathologic lesion of the liver found associated with the toxic jaundice of munitions workers is the same as that long familiar as acute yellow atrophy. The process is one of degeneration and necrosis of the liver cells, associated with infiltration and subsequent fibrosis resembling ordinary portal cirrhosis. The incidence of the disease can be overcome not by one precaution alone, but by the combination of several, of which alternation of employment, frequent periodic medical examination, ventilation, and clean working are the chief. Rolleston has thus summarized the prophylaxis of trinitrotoluene poisoning, of which cases are already being reported in this country:[4] In the first place, the absorption of the poison should be prevented by minimizing the opportunities of contact between the skin and trinitrotoluene. Every care must be taken to avoid spilling of the powder on the tables, floors, and the outsides of the shells and bombs. The hands should be kept clean, and freed from adherent trinitrotoluene by a solvent, such as acetone. Similarly, the hair and the underclothing must be kept free from the powder. Periodic alternation of shifts, so as to reduce the exposure to the poison, and prompt removal when toxic symptoms threaten, are essential. Good ventilation, substantial meals, and exercise are important to maintain a good standard of health and to keep the bodily resistance high. The application of prophylactic measures of this order has already resulted most satisfactorily in the munition works of the British Admiralty, where thousands of employees are involved.

The manufacture of trinitrotoluene in this country is mainly confined to a few firms, so that effective supervision can be planned. The loading of shells, on the other hand, is likely to be carried on by any manufacturer possessing the requisite facilities, which are comparatively simple. In a paper on the safe handling of trinitrotoluene, read before the Section on Industrial Hygiene of the American Public Health Service, Surgeon Schereschewsky of the U. S. Public Health Service pointed out that the number of workers involved in loading operations is likely to be much greater than that concerned in the manufacture of this substance. Besides this, he added, long contact with the production of other poisonous nitrated benzene products should have given manufacturers of trinitrotoluene the requisite experience to enable them to handle the manufacture of this substance with safety to the workers concerned. In addition to this, in the manufacture of trinitrotoluene, except at the final sieving and packing operations, the substance is handled either in closed containers or in a moist condition, under which circumstances the risk of poisoning is greatly reduced. In loading operations, on the other hand, there is constant opportunity for nearly every one connected with such work to become the subject of chronic poisoning through either the fumes or the dust of this substance. Valuable practical points have been outlined by Schereschewsky[5] in a recent number of *Public Health Reports* which should be in the hands of every one interested.

CONDITIONS AFFECTING THE FORMATION OF RED BLOOD CORPUSCLES

The normal response of the organism to a loss of red blood corpuscles, such as occurs through hemorrhage, consists in an increased activity of the blood-forming cells of the red bone marrow. New erythrocytes are formed to replace those of which the circulation has been deprived. This corrective mechanism, if it may so be termed, is the wholesome device whereby a harmful diminution in oxygen-carrying capacity of blood is prevented and the necessary factors for proper tissue respiration are restored. Heretofore it has not always been easy to follow the course of a regeneration of red corpuscles or to investigate the process at the seat of their formation, for, as Starling[6] has expressed it, in the confused medley of colorless cells which exist in the bone marrow and are precursors of all the varied corpuscles found in the blood, it is difficult to be certain of the identity of the colorless erythroblasts and to distinguish them from the smaller colorless cells engaged in the bone formation or in the production of leukocytes.

More recently a helpful new method of following the hematopoietic activities of the bone marrow has been devised by the study of the so-called reticulated corpuscles in the blood. When fresh, unfixed blood is treated with solutions of various dyes, such as brilliant cresyl blue, polychrome methylene blue or neutral red, a remarkable otherwise invisible structure is detectable. In suitable prepared specimens a granulofilamentous or reticulofilamentous substance appears in the form of coarse granular particles which are sometimes discrete, but more often occur in threads which are woven into skeins or wreaths of great complexity and fill a considerable portion of the cells. According to Vogel and McCurdy,[7] in the blood of infants these reticulations are found in from 5 to 10 per cent. of the erythrocytes, and in normal adult blood in from 0.5 to 2 per cent. In severe anemias, however, their number is much increased, running as high as 18 or 20 per cent.; while in hemolytic jaundice, which is the condition par excellence for their prevalence, they may occur in still greater proportions. Vogel and McCurdy believe that the filamentous substance is not a preformed structure, but is a precipitation product of the stain. They regard it as an evidence of youth in the cells and not of degeneration. Vogel and McCurdy thus present the significance of the reticulated cells: In conditions in which a severe drain on the erythrocytes is being sustained by a well functionating bone marrow, large numbers of reticulated cells are found; whereas in aplastic cases they may be diminished almost to the point of absence; that is, in a manner somewhat comparable to the behavior of the erythroblasts, the reticulated cells afford a direct insight into the hematopoietic activities of the bone marrow. For clinical purposes they form a more convenient measure of this function than do the nucleated cells, as their percentage relations to the erythrocytes can be more easily and accurately determined, and their enumeration is to be urged as a part of the study of the blood in all cases of severe anemia.

[6] Starling, E. H.: Human Physiology, 1915, p. 834.

By enumeration of the reticulated cells as well as by various older modes of investigation, the stimulating effect of loss of blood on the regeneration of blood cells has been put beyond question. Indeed, it appears that the bone marrow functions constantly in supplying new red corpuscles to replace those lost daily in the process of normal blood destruction. How shall we picture the functioning of the active marrow under conditions in which a need of erythrocytes is not imperative, that is, when there is a plethora of them? This is precisely the situation after the transfusion of blood.

Experiments have recently been conducted in the laboratories of the Rockefeller Institute for Medical Research by Robertson[8] to determine whether a diminished activity of the bone marrow can be brought about in animals by plethora produced by repeated small transfusions of blood. Counts of the number of reticulated red cells in the circulating blood were made during the course of the experiments as an index to changes in the activity of the bone marrow. With the development of plethora, the number of reticulated cells in the blood decreased. In the majority of the plethoric animals, this diminution was extreme, and in some instances, reticulated cells practically disappeared from the blood. A comparison of the red bone marrow of these animals with that of normal controls revealed a marked reduction in the content of reticulated cells. After a number of transfusions, there occurred in some of the plethoric rabbits a sudden and marked drop in hemoglobin. The hemoglobin continued to fall until a severe grade of anemia was reached. This was followed by a striking rise in color index. During regeneration the reticulated cells were enormously increased in number.

As Robertson notes, these facts taken together show that the bone marrow is markedly influenced by plethora. There is a very practical application of the findings to the management of certain cases in which transfusion is currently employed. It has been stated that greater judgment is needed in determining the amount of blood to be transfused. Thus Vogel and McCurdy believe it quite possible that too large an amount of transferred blood may be injurious in pernicious anemia, in which transfusion is a valuable form of palliative treatment. The experience of Robertson may account for the diminished bone marrow activity which sometimes occurs after transfusion. In such cases, he explains, there is a marked drop in the number of reticulated cells and other evidence of bone marrow depression; the patient shows no benefit from transfusion, or may grow rapidly worse. The cause of this depression is best explained on the basis that in severe instances of the disease, when exhaustion of the bone marrow is imminent, the stimulus of the anemia is only just sufficient to keep the marrow functioning. A sudden lowering of this stimulus is brought about by the introduction of a large quantity of blood into the circulation, and the result is a fall in the activity of the bone marrow. It follows from this that in pernicious anemia with a feebly reacting bone marrow as indicated by the number of reticulated red cells, small transfusions are preferable to large ones.

Sanitary Waste Disposal Systems for Unsewered Towns and Villages.—Public Health Bulletin 89 of the Public Health Service concerns a sanitary privy system for unsewered towns and villages, and gives details for the construction of sanitary privies which may be applied to existing buildings. A number of towns in various states, particularly in the South, not having sewerage systems, have adopted the sanitary privy system as described in the bulletin. Among them is Tuscaloosa, Ala., which passed an ordinance providing for the installation of this system and regulations for effectively carrying out this method of waste disposal. The ordinance in Tuscaloosa was backed by strong public sentiment and was rigidly enforced. Prior to the installation, there were 1,158 open, insanitary privies. As an indication of the effect of this sanitary measure, it is shown that typhoid fever was reduced from 190 cases and 17 deaths in 1915, the year before the sanitary work was done, to 14 cases with 1 death for 1916. Of the cases occurring in 1916, six gave histories showing that the infection was contracted *outside* of the city.

Current Comment

THE SOURCE OF ENERGY IN THE BEATING HEART

It is now generally accepted that although muscular work can probably be performed at the expense of any of the foodstuffs or the three proximate classes of constituents of the body, carbohydrate is the immediate or most readily available source of muscular energy. The respiratory quotient, or ratio CO_2/O_2, would be equal to unity if the entire requirement for energy were satisfied by the oxidation of carbohydrate; that is, the output of carbon dioxid formed would be exactly equal in volume to the oxygen required. As a matter of fact, Benedict and Cathcart[1] found in their extensive studies of muscular work that there is almost always a rise in the respiratory quotient during work. After the cessation of the exercise, the respiratory quotient sinks again. During a "century run" on a bicycle, the respiratory quotient remained at about 0.9 throughout the experiment, indicating that the body's glycogen was being used in goodly measure. An interesting confirmation, so to speak, has been furnished in a quite different manner by Snyder,[2] who has accurately measured the average amount of heat liberated per beat and gram of tissue by the ventricle of surviving hearts. He has calculated the quantity of glucose required to yield the measured calories, and finds it to be essentially equivalent to the amount demanded by the corresponding carbon dioxid production of the beating heart as well as to the amount found by Clark[3] to disappear in contracting hearts. Therefore, Snyder argues, glucose or some carbohydrate of equal heat of combustion is the presumable source of the heat liberated by the beating heart.

PHYSICAL RECONSTRUCTION

In this country prior to the war there were thousands of physically handicapped men who through lack of training were unable to make a living. Unfortunately we have been as prodigal of human brain and brawn as of money and material, and in the years past we have made no systematic attempt at human salvage. The terrible ravages of this war in men and materials acutely emphasize the importance of the work of physical reconstruction and reeducation in its relation to world economy. The time has arrived when conservation has become acutely necessary, conservation not only of material but also of men, and not only of men but also of human energy. The time has passed when we can afford to discard as derelicts those whose capacities do not measure up to our standard of efficiency. Our allies unfortunately "had no precedents to guide" in the care of their injured soldiers. The lessons learned from the experience of all the warring nations are available. Though meager, as compared with the complexity of the problem, these lessons point with precision to one necessity—military control. From every hand comes the advice to hold the soldier until he is prepared to return to work in civil life. Division of duties and authority has in the countries of our allies resulted in discontent and unsatisfactory conditions. This we can avoid because there is yet time for us to evolve a system that will place the responsibility of action where it rightly belongs. Reconstruction is both physical and mental. A large and important phase belongs in the domain of surgery; however, readjustment is not always accomplished by an operation; it is found equally as important that vocational training should be carried on in the hospitals, not only on account of its educational but also because of its therapeutic value. Occupation speeds recovery, idleness retards it. The problem, after all, is to determine the best means to give the man an opportunity, in spite of his disability, to earn a livelihood. The decision of this question should rest with the department of the government charged with the responsibility of the physical care of the soldiers, the department which opens the gate for his entrance into the Army, follows him down that dangerous path of duty, works to restore him when incapacitated, and studies under the most intimate associations his physical and mental abilities—the Medical Department of the Army.

MUSCULAR WORK AND THE BLOOD

At a time when millions of persons are applying their energies to a degree that the world has probably never known before, it is important to understand thoroughly the physiology of muscular exercise. It has long been known that changes occur in the blood as the result of exercise. Muscular work, whether moderate or severe, produces a rise of blood pressure and an acceleration of the pulse. There are alterations also in the composition of the blood. The number of red corpuscles is noticeably increased; and this result appears on first consideration as a most beneficent phenomenon whereby a greater oxygen-carrying capacity is imparted to the circulating fluid at a time when the demand for oxygen in tissue respiration is decidedly augmented. The explanation of this enrichment of the blood in red corpuscles as an incident of muscular exercise has not been uniform. Some authors[1] have explained their results on the basis that there are masses of corpuscles stored away in certain organs that may be liberated in time of need, while Lamson[2] believes that the number of corpuscles is altered by a splitting of old corpuscles or a production of new ones, as well as by storage in the liver. More recently, Scott[3] of the University of Minnesota has come to the conclusion that the capillaries of special organs do not thus contain large numbers of corpuscles that may be liberated at any moment and pass into the general

circulation. He has compared the capillary blood of various organs with that in the larger blood vessels, and has always found them practically identical in hemoglobin content. Consequently, Scott argues, one may consider any alteration in the hemoglobin value or corpuscle mass found within a few minutes as due to the passage of fluid out of the blood to the tissues, or vice versa. Scott has demonstrated that the hemoglobin content of the blood is rapidly modified by any alteration in blood pressure, a rise of pressure leading to an increase of hemoglobin, and a fall to a decrease. These results can be explained only by the forcing of fluid by the increased pressure out of the blood tissue spaces, and the passage of fluid back from the tissue spaces to the blood when the pressure is lowered. In view of the fact that a rise in blood pressure invariably attends muscular work, the increment in corpuscles can thus be explained. Furthermore, there is an increase in the water content of muscle as a result of contraction, if the blood is circulating through it. Thus a passage of fluid from blood to muscles comes about, whereby the alterations in blood composition are further facilitated.

EXPERIMENTAL SCURVY—A HISTORICAL NOTE

The credit for demonstrating and describing the production, in animals, of a condition resembling scurvy in man is usually ascribed to Professor Holst and his co-workers in Christiania, Norway. In 1912, he published a report of his now classic experiments on the symptoms and pathologic lesions produced in guinea-pigs by means of a diet of cereal grains.[1] His observations have frequently been repeated, notably by Baumann and Howard, H. B. Lewis, Jackson and others in this country.[2] Hess[3] has recently pointed out the little known fact that comparable findings of typical symptoms in guinea-pigs were reported much earlier by one of America's foremost comparative pathologists. In a bulletin on "Bacilli in Swine Disease," published by the Bureau of Animal Industry, 1895-1896, Theobald Smith says (p. 172): "When guinea-pigs are fed with cereals (it has been observed for some years in this laboratory), with bran and oats mixed, without any grass, clover or succulent vegetables, such as cabbage, a peculiar disease, chiefly recognizable by subcutaneous extravasation of blood, carries them off in from four to eight weeks." Thus another instance of keen scientific observation is added to the record of the discoverer of the transmission of infectious disease through the intermediation of insects, and the original observer of the fundamental phenomena of what is now termed anaphylaxis.

Progress.—Progress is not an accident, not a thing within human control, but a beneficent necessity.—Herbert Spencer.

Medical Mobilization and the War

PHYSICIANS AND THE SELECTIVE SERVICE

The Journal has been flooded with inquiries as to whether a physician may apply for a commission in the Medical Reserve Corps after December 15. The questions arose from the general announcements in newspapers that, according to the Selective Service Regulations, no registrant might enlist voluntarily after that date. Section 151 of the new Regulations states:

> "(c) Any registrant at any time, regardless of classification and order number, may be commissioned in the Army, Navy, or Marine Corps, or appointed an army field clerk, and thereafter, on presentation by the registrant to his Local Board of a certificate of his Commanding Officer stating that he has been so commissioned or appointed, such certificate shall be filed with the Questionaire and the registrant shall be placed in Class V on the ground that he is in the military or naval service of the United States."

The effect of placing in Class V is to exempt from the draft. It is, of course, obvious that a physician who has received a commission in the Medical Reserve Corps is subject to the orders of the Surgeon-General and must accept active duty whenever he is ordered into service.

It is desirable from the standpoint of those physicians who are registered that they act promptly. If a physician is ordered into service by his draft board before receiving his commission, he must go to the cantonment with his quota and will be held there as a private until the commission and orders to active duty are received. In connection with the first call, many physicians were in this condition, and numerous letters have been received from physicians who were serving at privates' wages in the cantonments, awaiting action on applications for commissions made through the division commander of the Medical Department after the physicians arrived in camp. The same delay is likely to occur in the future, so it behooves those who desire commissions to act promptly. Application blanks and general information will be sent by The Journal on request, accompanied by a self-addressed stamped envelope.

DEPENDENCY

A great many physicians have written to The Journal asking whether the rules governing dependency would apply to physicians as well as to others registered under the Selective Service. According to the Selective Service Regulations, "it is not the intent of the law to deprive the dependents, whom the law and regulations are designed to protect, of a reasonably adequate support. No definite degree can be given to the meaning of the term 'reasonably adequate support' as used in the classification rules and schedule. The adjustment of these rules must be left to local boards." The local board must, of course, consider the physician in the same light as any other registered man. It cannot consider him as a commissioned officer until his application has been accepted and the commission has been issued to him.

AMERICAN RED CROSS IN FRANCE

The work of setting in motion the activities of the American Red Cross in France is described by Paul U. Kellogg in the *Survey*, Nov. 24, 1917. Paris is the center of the work, at which place the commissioner and a number of deputies arrived, June 12, 1917. This is a working organization to project among a friendly people the instruments through which the funds raised in the United States could be brought to bear wherever and in whatever ways they would count for the most. In January, 1918, or six months from the beginning, it is expected that about 1,000 persons will comprise the executive force. There is to be a string of warehouses along the front extending from Dunkirk to Dijon, with reserve warehouses back of them and in the devastated areas, floating warehouses in Belgium, ready for any advance in the lowlands, great storage centers in Paris, receiving houses at all ports of entry, and purchase and supply stations in Great Britain, Switzerland, France, Spain and Portugal, as well as in America. The distribution of hospital supplies has been coordinated in a single agency, reaching 3,617 hospitals in 1,356 towns. Plants for the manufacture of special medical supplies, bureaus for the exchange of surgical methods, and reserves to stand back of the medical department of the American Army are being built up by the military affairs department, which is also establishing a canteen system that eventually will reach 1,500,000 French soldiers every month.

The duties of the American Red Cross in France are set forth as follows: First, to serve the Army of the United States; second, to serve the sick and wounded of the allied armies, and third, to give such general assistance as it can to the French people.

FROM AN M. R. C. IN FRANCE

The following letter is from a major in the Medical Reserve Corps, U. S. Army, who has charge of one of the base hospitals in France. The letter was personal and not for publication, but some parts of it are so interesting that they are reproduced.

We are still in the same location "Somewhere in France," and continue to carry on in this large hospital with its continuously increasing amount of work. It is very gratifying to be able to report that our relationship with the good British medical officers and authorities continues to be most cordial, with surprisingly little friction.

We have now been here long enough to take stock of the attitude of the medical officers coming from civil life and of their adaptability to do military surgery. The very loyal support that the medical officers of this organization have given to us throughout our association has been extremely pleasing. One notices a striking contrast to the friction that sometimes one observes in organizations of a like character in civil life.

All of the officers are accepting the necessary military control and discipline, and are coordinating in an intelligent and most satisfactory manner. They all seem to be able to forget their individual desires and conveniences, and to make their own opinions subservient to the direction of the people in higher authority.

Judging from our experiences, I believe it can be said without fear of contradiction that the men in the Medical Reserve Corps are rendering a splendid service and showing a disposition to work in perfect harmony with the Army Medical Corps. Obviously, it is necessary to have the most perfect accord and cooperation, in order to secure the most adequate organization to carry on the medical and surgical work in this great conflict.

I feel that the attitude and adaptability of the Reserve Corps officers will make the correlation relatively simple. Each and every one of the men in this organization has learned the necessity of military rules and regulations very rapidly, and I am sure that our good commanding officer, Col. C. C. Collins, has nothing of which to complain in this direction. Possibly some of this is due to his thoughtful consideration and diplomatic method of dealing with the situation. Throughout the whole organization there seems to be a realizing sense that we have a hard job to do and that it must be done with cheerfulness and cooperation.

Naturally, it is every good American's desire to go behind his own lines when the occasion arises for this necessity. At present it would appear that this eventually will probably occur.

I wish it were permissible to tell you how many patients we have treated at this hospital during the month of October. I can assure you that the number was exceedingly large. The medical personnel of this organization is having an opportunity for a wide and unusual experience in war surgery, and is responding to it in a most satisfactory manner, showing better surgical judgment each day.

We have now been here nearly six months, and I think our experience justifies us in stating that there is very little in war surgery that is not covered by the general surgical principles as laid down in civil life. One of course has to deal with pathologic conditions a little more complicated, because of the more serious and virulent types of infection with which we are brought in contact. There is a certain psychology in war time, I think, which makes all men somewhat more radical; and this applies to the medical department as well as to other branches of the service. In this connection I find it is necessary to exercise a little control and restraining influence in the direction of conservatism regarding the saving of limbs and the preservation of tissues that are sometimes sacrificed by the too extensive excision of infected areas.

I think we are all agreed that the time that elapses between the infliction of the wound and the first adequate surgical treatment is an all-important factor. I should like to lay emphatic stress on this essential element of time in the treatment of the wounded, believing that in the organization of the surgical and medical work for the American Army this should be one of the fundamental considerations; and to this end, men familiar with large transportation problems should be consulted in developing a system for rapidly conveying the wounded to a place where adequate surgical treatment can be instituted.

I am very much impressed with the French so-called "perpendicular" plan of organization. This means that the wounded man is under the direction of the same organization from the time he is wounded until he reaches the ultimate base in the center of the country. This permits a single and unified method of treatment throughout his illness and convalescence.

I am convinced that any method which does not allow for a cooperative control of the patient as he passes from one hospital to another will not give the best results.

The Journals continue to come through more promptly than any other mail we receive. The reason for this, I do not know.

NEWS OF THE CANTONMENTS

Thirty-First Division, Camp Wheeler, Macon, Ga.

MEASLES AND PNEUMONIA

The measles epidemic is practically over, less than 100 of these patients now being in the hospital. The number of new cases of pneumonia grows somewhat less, but is still uncomfortably high. The mortality rate has also increased to about 18 per cent. It is believed that many more Type I and II cases are being found than formerly. The precautions against pneumonia in the camp are now about the same as against any other infectious disease. They include compulsory airing and sunning of tents; use of spit boxes with sand wet with cresol; washing of all tent floors with cresol solution daily; prohibiting spitting except in spit boxes, and isolation of all convalescent patients. Heavy clothing and three blankets have been supplied in all cases. Major Zinsser is making a careful epidemiologic study of the disease. While the partial grouping of cases points to infection, there can be no doubt that poor physique and low vitality are important predisposing factors.

ONE HUNDRED AND SIXTH SANITARY TRAIN

It is believed that the One Hundred and Sixth Sanitary Train is more nearly ready to take the field than any other organization in the division.

Captain Cupper of the British infantry, detailed as instructor in bombing in the division, gave a most interesting talk to the officers of the Medical Corps at their meeting last Monday afternoon. The captain has promised to lecture to the noncommissioned officers of the train at an early date, giving them the value of his long experience at the front.

New sanitary measures have been instituted tending toward the stamping out of the pneumonia epidemic. Not more than five men are allowed in each tent. Tents are mopped out with cresol solution each morning. Two sputum boxes to each tent and sputum boxes in each company street containing cresol solution are required. Guards are maintained at all times to see that tent doors are open and that these sanitary measures are enforced.

The ill from the sanitary train are handled similarly to the ill of a regimental infirmary. Each field hospital handles the dispensary one month at a time. Field Hospital No. 121 was relieved by Field Hospital No. 122, December 1, and will care for the ill for a period of one month.

We still have hopes of enjoying some day a hot bath, when the intricate heating system is finally installed.

BASE HOSPITAL NOTES

The roentgen-ray department is having a series of unusually interesting cases.

Frames for field hospital tents have been made and installed, and board walks from the corridors and tents are being made.

Major Hans Zinsser of the Surgeon-General's Office is here doing special epidemologic work with reference to pneumonia and meningitis. He is charting the camp and studying the situation from the standpoint of contact infection. He instituted a campaign against the careless disposal of sputum. Only five men are allowed to occupy each tent among the enlisted men, by direction of the Surgeon-General.

Lectures are delivered each night to the staff by one of the chiefs of service. These are proving both interesting and instructive. There is in process of evolution a recreation room for the use of the enlisted men.

Thirty-Fifth Division, Camp Doniphan, Fort Sill, Okla.

DISEASE INCIDENCE

Rain and colder weather materially increased the number of cases showing involvement of the respiratory tract, and "colds" are common. For the week ending November 30, the number of cases of pneumonia had increased to forty-nine. Quite a number of these cases are developing as a complication to measles, of which there are at present eighty-three cases in camp. There were five deaths during the week, four following pneumonia and one due to tuberculous meningitis. The necropsy in the cases of pneumonia following measles has quite uniformly shown the streptococcus. In all of these cases a marked fibropurulent pericarditis with effusion was found. Thus far, no new cases of cerebrospinal meningitis have developed, and the camp has only two of these cases to record at present. Prompt isolation of all contacts, and energetic treatment of these contacts with dichloramin-T in an oily medium, as furnished by the office of the Surgeon-General, appear to control the situation satisfactorily. The use of a plain oil spray seems to give equally good results, and has the advantage that it can be more easily applied, since it is less viscid than the oil to which dichloramin-T has been added. The oil spray is used every two hours in a de Vilbiss atomizer.

The transfer of patients into the new base hospital is now well under way. Practically all of the medical patients have already been transferred.

As soon as the operating rooms and the rooms for the specialists and the laboratories have been completed, the transfer of all patients from the post hospital, where they have until now been accommodated, will be made. It is expected that this will be effected during the ensuing week.

PERSONAL

Lieut. John A. Walker, M. R. C., of the base hospital, has been ordered to Oklahoma City, where he will be given a special course in orthopedic surgery.

Eightieth Division, Camp Lee, Petersburg, Va.

THE SANITARY TRAIN

Work in the sanitary train is progressing satisfactorily. The field hospital section is under the direction of Capt. Elliott B. Edie, M. R. C., and the ambulance section under the direction of Capt. Burr Ferguson, M. R. C. The regular course of instruction for medical officers and enlisted men is being carried on daily. The first hike was made, December 4, when the entire train marched to beyond Prince George Court House, where dinner was cooked on field ranges. Lieutenant-Colonel Rhoads, the division surgeon, visited the officers and men while at dinner and expressed himself as satisfied with the first practice march. There were several officers and men with sore feet, and Colonel Rhodes spoke to the officers and men on the care of the feet while on the march.

The sanitary train has an excellent football team, and has played a number of games with other organization teams at Camp Lee, and one outside game. Lieut. Joseph M. Barsky, M. R. C., Three Hundred and Twentieth Ambulance Company, and Lieut. James W. McPheeters, M. R. C., Three Hundred and Eighteenth Ambulance Company, play.

The Richmond Red Cross recently presented twelve standard ambulances and three motor trucks to the Three Hundred and Nineteenth Ambulance Company, and other equipment valued at $40,000. This company was organized in Richmond, and is under the command of Capt. Charles Howard Lewis, M. R. C., of that city.

December 4, Lieut. O. W. Budd of the Three Hundred and Twentieth Infantry gave an illustrated talk to the officers of the sanitary train on ambulance work in France. Lieutenant Budd has served with the American Ambulance in France and gave the officers a number of practical pointers. Lieutenant Budd told the officers that it was necessary for the ambulances to have wooden sides instead of canvas, and that ambulances in France have been modified to allow stretchers to be easily pushed in instead of requiring the use of a hook to hold the upper tier of stretchers. The lecture was most practical, and was appreciated by all the medical officers.

THE WORK OF SPECIAL NEUROPSYCHIATRIC BOARDS

The neuropsychiatric board under the direction of Major James R. Moore, M. R. C., had 179 cases referred to it during the months of September, October and November. Among these were found 45 cases of nervous disease, 10 psychoneuroses, 22 cases of alcoholism, 6 drug addicts and 33 mentally deficient. Eighty-four men were discharged on account of disability.

TUBERCULOSIS

The tuberculosis board, under the direction of Capt. George D. Hamlen, M. R. C., has begun a complete examination of the entire command. The men of the Three Hundred and Fifth Engineers have all been examined, and the number of active tuberculosis cases found approximates 1 per cent. Prior to the work of the board, 108 white and forty-seven colored men were rejected for active tuberculosis.

ORTHOPEDIC WORK

Capt. James T. Rugh, M. R. C., reported, December 4, to instruct regimental surgeons on the care of the feet and the prevention of orthopedic defects. At the regular weekly clinical meeting held at the base hospital, December 6, Captain Rugh gave a most instructive lecture on the anatomy and mechanism of the foot and the treatment of minor defects. The lecture was much appreciated by all the medical officers present.

GENERAL HEALTH CONDITIONS

During the past five week there have been 338 cases of measles and 421 cases of mumps, the majority of the cases being confined to one regiment. As a result of these diseases, the noneffective rate during this period has gradually increased from 1.2 per cent. to 3.8 per cent. Except among the colored troops, the venereal disease rate has been low; but over 90 per cent. of all the cases occurred prior to enlistment.

PERSONAL

Lieut. William J. Robbins, M. R. C., was thrown by a bucking bronco, November 25, and sustained a fracture of the neck of the femur.

Lieut. Romanus A. LaGrinder, S. C., N. A., medical supply officer, has been promoted to captain and ordered to Newport News, Va. His place has been taken by Capt. Rush Cameron, S. C., N. A.

Capt. E. J. Tucker, S. C., N. A., has been at camp for two weeks to study the water supply and sewage disposal system.

Capt. Lauren Thomas, M. R. C., has been ordered to his home.

Major Linsly R. Williams, M. R. C., delivered the Harvey Lecture at the Academy of Medicine in New York, November 24. The subject of the lecture was "Medical Problems of the War."

Lieut. Benjamin C. Cliff, M. R. C., was married, December 2, at Richmond to Miss Earline Eugenia Hart.

Major Henry P. Carter, M. C., U. S. Army, divisional sanitary inspector, has been transferred to Camp Logan, Texas. Major Carter left Camp Lee, December 4, and will be much missed by the medical officers of the division.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

Louisville has felt wintry blasts since the night of the 6th, when 17 inches of snow fell, burying the camp in a white blanket. Most of the building roofs have not been equal to the strain and but few have escaped leaks which have been very inconveniencing to say the least. The barracks have been kept warm by the large drum stoves by which they are heated, but the patients in the base hospital have in many wards suffered keenly from the cold. For some reason the steam pipes leading to the various units, not connected by corridors, are carried on stilts 8 or 10 feet in the air, and with no return line for water of condensation and zero weather, those buildings farthest away from the power plant, several city blocks, are practically without any heat.

Snow has drifted through cracks around the ventilators in barracks and canteens, and caused considerable damage when it melted. A stock of cigarettes in the canteen of the Three Hundred and Thirty-Fourth Infantry, worth several hundred dollars, was ruined.

Railroads and city cars refused to accept shipments of milk for the camp on account of the snow blockades, and Lieutenant Shaw, adjutant at the base hospital, had to requisition four Quartermaster Department four-mule teams to haul 40 gallons of milk from the city to the patients.

The failure of the city railway to clear away the snow from the tracks leading to the camp and necessary discontinuance of car service caused great inconvenience of the thousands of soldiers on leave during the afternoons of last

Saturday and Sunday. Jitney busses charged $1 and $2 for the trip from Louisville to the camp.

Four hundred picked men from various organizations have been transferred to the Aviation Camp at San Antonio, Texas.

Dr. Clarence H. Ketterer of Butler, Pa., has been detailed to Camp Zachary Taylor as a junior member of the physical examining board and medical member of the board, Aviation Section of the Signal Corps, and has reported to division surgeon Col. John H. Allen. From this detail it is believed that applicants for the officers' training school for aviators are to be examined here. Authority has been received to accept 200 applicants possessing certain qualifications as students in the Aviation Corps. Applicants for this service are more rigidly examined than for any other branch. A revolving chair has already been received and is placed in the head surgery section of the base hospital.

War Department orders have been issued prohibiting the publication of rosters of officers or men during the period of the present emergency.

Six hundred and sixty-two soldiers have been discharged by the special tuberculosis board, of which Captain Lichty of Cleveland is president. A little over half of the division has been examined by the board.

NEW SANITARY REGULATIONS

Major Poust, the division sanitary officer, as the result of recent inspections of the camp, has issued a new form of instructions to improve sanitary conditions at the cantonment. The bakers are required to manicure their nails carefully each day, and before they go on duty there will be an inspection of hands by commissioned officers.

In regard to sleeping arrangements in the barracks, the beds are to be stationed so that every other man will sleep with his feet opposite the head of the man alongside. This will allow a space of 5 feet between heads and greatly reduce the chances of the spread of respiratory diseases. A certain number of windows in every barrack are to be kept open during the night, and a commissioned officer will be required to make inspections of the barracks twice each night to see that the order is being enforced.

SCHOOL FOR HYGIENE AND SANITATION

The school for hygiene and sanitation has been established, the course begining December 3. A medical officer has been appointed commandant of the school. Unlike most of the divisional schools, only commissioned officers will be required to take the course. The instruction will consist of sanitation in garrison, camp, on the march and in campaign.

BASE HOSPITAL ACTIVITIES

There are 730 patients in the base hospital, between 450 and 500 being purely medical. New wards have been established, one for hookworm patients and one each for active and suspected tuberculosis patients. Specimens from each patient in the hospital have been examined for hookworm, and eighteen positive cases have been found. These men will be vigorously treated and reexamined before being discharged.

With the arrival of the last 35 per cent. of the draft, 42,000 men will be in the camp. The quarters are adequate to receive them, and there are plenty of clothes and food.

ILLNESS IN MEDICAL STAFF

One officer and one nurse were admitted to the hospital, December 2, with measles.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

Everything is running smoothly in the Eighty-Ninth Division. Transfers from one branch of the service to another have about been completed. This week the colored regiment of the division was taken over by the Ninety-Second Division. The total number of whites rejected to date is 615, colored 51, grand total 666. There are at present thirty-seven rejections pending final action. One hundred and thirty-seven of these rejections were for pulmonary tuberculosis. This list is not the list of the medical examiners alone, for many men have appeared for examination on their own behalf. Not long ago a general order was issued, granting each man the right of reexamination if he believed his case had not been given proper attention.

The detention camp, capacity 2,500 men, built half way between this camp and Fort Riley, is now in full operation. The need of such a camp in as large a command as this is apparent, when one learns that it cuts down the noneffective number by one third.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Nov. 30, 1917

1. Total strength of troops in United States as reported.....1,051,424
Annual admission rate per 1000 (disease only).......... 1,423.6
Non-effective rate (all divisions) 37.4
2. National Guard, strength (divisions in United States).... 400,115
Annual admission rate per 1000 all divisions (disease only) 1,448.6
Non-effective rate all divisions (all causes) 43.9
Divisions showing admission rate for disease higher than average: Camps Bowie, Cody, Kearny, Wheeler, Doniphan, Shelby and Beauregard.
Divisions showing non-effective rate all causes higher than average: Camps Bowie, Beauregard, Kearny, Shelby, Wheeler, Cody, MacArthur, and Sevier.
3. National Army, strength (divisions in United States)......433,951
Admission rate per 1000 all divisions (disease only)...... 1,423
Non-effective rate all divisions (all camps)............... 32.5
4. Venereal Disease:
Annual admission rate Regulars in United States 97.4
Annual admission rate National Guard (Divisions in U. S.) .. 100.7
Annual admission rate National Army (Divisions in U. S.) .. 104.3
5. Number of Cases of Pneumonia 438
Highest number in any one division, Bowie (36th Div.)..... 166
Number of cases of meningitis 57
Highest number in any one division, Funston (89th Div.)... 12

6. NEW CASES OF SPECIAL DISEASES REPORTED DURING THE WEEK ENDING NOV. 30, 1917

To Camp Dix, Wrightstown, N. J., base hospital, from Camp Greenleaf, Capt. CLARENCE F. M. LEIDY, Philadelphia.

To Camp Greene, Charlotte, N. C., for duty, from Army Medical School, Lieut. JOHN J. MOORE, Pottsville.

To Camp Lee, Petersburg, Va., for duty in the base hospital, Lieut. JOSEPH F. O'NEILL, Philadelphia.

To Camp Lewis, American Lake, Wash., for duty, from Fort Oglethorpe, Lieuts. JOSEPH A. PESSOLANO, Philadelphia; ALFRED L. RHOADS, Scranton.

To Camp Pike, Little Rock, Ark., base hospital, from Fort Oglethorpe, Capt. SAMUEL I. EBER, Pittsburgh; Lieut. CHARLES E. HAYS, Johnstown.

To Camp Sevier, Greenville, S. C., for the purpose of examining the command *in his specialty, from* Psychopathic Hospital, Ann Arbor, Mich., Lieut. ERWIN H. ERNEY, Philadelphia.

To Camp Sherman, Montgomery, Ala., for duty, from St. Elizabeth's Hospital, Lieuts. EMORY L. DRAVO, Warren; from Fort Riley, CHARLES G. MOORE, Pittsburgh.

To Fort Oglethorpe, Ga., for instruction, Lieuts. CHARLES B. YOST, Bloomsberg; CLARENCE E. KING, Brick Church; WILLIAM C. BROWNE, Burnside; FRANK R. NOTHNAGEL, Chester; HARRY J. STOCKBERGER, Claridge; ARTHUR D. COWDRICK, Clearfield; J. MERLE EVERWINE, Clymer; WALTER M. BORTZ, Greensburg; CLAUDE W. McKEE, Greensburg; PETER E. EAGAN, Hazelton; JAMES F. TIMBLE, Jeannette; FRANK G. SCHARMANN, Johnstown; GARNETT P. MORISON, Latrobe; JOSEPH H. WYATT, Mahanoy City; JAMES J. O'CONNOR, Mildred; JOSEPH W. POST, Millersburg; FRANK H. GARDNER, Montrose; WILLIAM E. ANDREW, Penn Argyl; GERSHON GINSBURG, CARL F. KOENIG, WILLIAM C. KOSSLER, JOHN J. NEAL, JOHN R. QUAY, Philadelphia; CHARLES E. PEACH, Pine Grove; ABRAHAM FINKELPEARL, FREDERICK V. LICHTENFELS, WALTER A. MONNICH, MICHAEL M. WOLFE, Pittsburgh; ALFRED M. BERGSTEIN, Pottsville; CHARLES C. RYAN, Republic; JOHN F. PARK, South Bethlehem; PAUL G. L. HOCH, Tarentum; STACY H. RINEHARDT, Washington; BURGESS A. GIBSON, Washingtonville; CLARENCE H. KETTERER, Butler.

To Hoboken, N. J., for duty, from Camp Dix, Lieut. SAMUEL H. BOYD, Philadelphia; from Camp Greenleaf, Lieut. MOES T. KNAPPENBERGER, Pittsburgh.

To New York City, Neurological Institute, for intensive training in brain surgery, from Camp Beauregard, Capt. WILLIAM C. HEISEY, McKeesport.

To Oklahoma, Okla., for instruction in orthopedic surgery, from Chickamauga Park, Ga., Capt. CARSON COOVER, Harrisburg.

To Philadelphia, for duty with Base Hospital No. 30, from Jefferson Hospital, Capt. FRANCIS F. BORZELL, Philadelphia; *to Evans Dental Institute*, for instruction, and on completion to Camp Devens, Capt. CARLTON N. RUSSELL, Philadelphia.

To St. Louis, Mo., Washington University, for instruction, from Fort Oglethorpe, Lieut. ROBERT E. STRASSER, Reading.

To Walter Reed General Hospital, Takoma Park, D. C., to exhibit films showing the technic of dichloramin-T, and on completion of this duty to return to his proper station, Capt. WILLIAM H. FURNESS, Wallingford; Lieut. WALTER E. LEE, Philadelphia; for temporary duty from Evans Dental Institute, Lieut. ARTHUR T. HENRICI, Pittsburgh.

To his home and the inactive list, from Camp Greenleaf, Lieut. WILLIAM V. COYLE, Philadelphia; from Northwestern University, Lieut. SAMUEL McCLARY, 3d, Philadelphia.

South Carolina

To Fort Oglethorpe, Ga., for instruction, Major THOMAS R. MARSHALL, Columbia; Capt. MORGAN P. MOORER, Georgetown; Lieut. WILLIAM S. BURGESS, Sumter.

To Fort Riley, Kan., for duty with Evacuation Hospital No. 7, Lieut. HARRY E. JENKINS, Port Royal.

To Rockefeller Institute, for instruction, and on completion *to Camp McClellan*, Lieut. WALKER H. ROWE, Greenville.

South Dakota

To Fort Riley, Kan., for instruction, Lieut. HERSCHEL G. HARRIS, Wilmot.

Tennessee

To Camp Lewis, American Lake, Wash., for duty, Lieut. JAMES S. SKAGGS, Maynardville.

To Camp Sevier, Greenville, S. C., base hospital, from Fort Oglethorpe, Lieut. EUGENE M. ORR, Nashville.

To Fort Oglethorpe, for instruction, Lieuts. ELISHA FARROW, Bells; THOMAS C. CHAPMAN, Brownsville; JOSEPH H. CHANCE, Cedar Hill; JAMES L. JOHNSON, Chattanooga; WALTER A. BELL, Cloverdale; BENJAMIN B. WRIGHT, Covington; EMMETT E. BYRD, Jonesboro; HIRAM A. LAWS, Jr., Lynchburg; FRED O. STONE, Maynardville; EDWIN C. GILLESPIE, Memphis; GROVER C. ENGLISH, Mount Pleasant; AAREIEL E. GOODLEE, Murfreesboro; JAMES L. BRYAN, JAMES D. LESTER, Nashville; WILLIAM E. McGAHA, Newport; IRA O. PARK, Union City; DANIEL C. HAGGARD, Unionville; SWAN BURRUS, Woodland Mills; for duty with Evacuation Hospital No. 4, JAMES D. L. McPHEETERS, Chattanooga; for duty with Evacuation Hospital No. 6, LEONARD A. CROSBY, Memphis.

To Fort Riley, Kan., for instruction, Lieut. CALVIN G. STRICKLIN, Clarendon.

To Rockefeller Institute, for instruction, and on completion to Camp Gordon, Atlanta, Ga., for temporary duty in the base hospital, Lieut. GROVER C. CONYERS, Gates.

To St. Louis, Washington University, for instruction, from Fort Oglethorpe, Capt. JAMES BREW, Jr., Nashville.

Texas

To Camp Travis, Fort Sam Houston, for duty, from Camp Travis, Lieut. HENRY H. LOOS, Palacios.

To Fort Oglethorpe, Ga., for instruction, Lieut. BENJAMIN F. LARGENT, McKinney.

To Fort Riley, Kan., for instruction, Lieuts. ARCHER B. WORSHAM, Brashear; ROBERT E. FORESTER, Burleson; HARRY H. HENDRICKS, Dallas; MELVIN L. HUTCHISON, Dallas; OSCAR C. WEST, El Paso; LYLE J. LOGUE, Houston; JESSE G. JENKINS, Hubbard; JOSEPH J. ROBERTSON, Kingsville; MOULDON SMITH, Roby; JAMES P. McNULTY, San Angelo; WILBUR CARTER, Sherman; HUBERT FERRELL, Tyler; THOMAS V. JENNINGS, Winters, Runnells County.

To Fort Sam Houston, Texas, for temporary duty, from Fort Oglethorpe, Lieut. ELMORE B. GILBERT, Gorman.

To Fort Sill, Okla., as assistant to the director of the Gas Defense Department from Western Department, Lieut. ARTHUR W. C. BERGFELD, Sequin.

To Fort Worden, Wash., for duty, from Fort Oglethorpe, Lieut. EDWARD J. BURNS, Carrizo.

To New York, Neurological Institute, for intensive training in brain surgery, Lieut. WILLIAM W. SHORTAL, Dallas.

To Oklahoma, Okla., for instruction in orthopedic surgery, from Camp MacArthur, Lieut. MARION BROWN, Mexia.

To St. Louis, Washington University, for instruction, from Fort Bliss, Capt. CHARLES M. AYES, Houston; Lieut. JOHN C. THOMAS, Taylor.

Utah

To Salt Lake City, Aviation Section, Signal Corps, for duty, Lieut. ROBERT R. HAMPTON, Salt Lake City.

To St. Louis, Washington University, for instruction, from Fort Riley, Lieut. CLARENCE A. NYVALL, Salt Lake City.

Vermont

To Fort Oglethorpe, Ga., for instruction, Lieut. LEWIS F. McCARTHY, Essex.

Virginia

To Army Medical School, for instruction in orthopedic surgery, from Fort Oglethorpe, Lieut. FREDERICK P. SUTHERLAND, Richmond.

To Camp Devens, Ayer, Mass., base hospital, from Fort Riley, Lieut. IRA THOMAS, Aldie.

To Camp McClellan, Anniston, Ala., base hospital, from Fort Oglethorpe, Lieut. LESLIE T. RUSMISELLE, Lovettsville.

To Camp Mills, Garden City, L. I., base hospital, from Fort Riley, Lieut. THOMAS MILLER, Fincastle.

Washington

To Camp Kearny, Linda Vista, Calif., base hospital, from Camp Kearny, Lieut. PEARL C. WEST, Seattle.

To Fort Riley, for instruction, Capt. EDMUND S. WEST, North Yakima; Lieuts. ALVIA G. NACE, South Tacoma; JO BENNETT BLAIR, Vancouver.

West Virginia

To Fort Oglethorpe, Ga., for instruction, Lieuts. MILTON D. FLANARY, Charleston; GEORGE P. McCOY, Franklin; HOWARD M. BATSON, Handley; ESLEY T. LAKE, Nuss; WALTER S. LINK, Parkersburg; CHARLES L. MOORE, Upper Tract; COLIN R. WEIRICH, Wellsburg; MILTON E. JONES, Welch.

Wisconsin

To Camp Cody, Deming, N. M., base hospital, from Fort Riley, Capt. JOHN S. FOAT, Ripon.

To Camp Lewis, American Lake, Wash., for duty, from Fort Oglethorpe, Lieut. CLAUDE I. WHEATLEY, Milwaukee.

To Fort Riley, Kan., base hospital, from Fort Leavenworth, Capt. MILTON W. HALL, Mondovi; from Fort Riley, Lieut. CHARLES A. YATES, Bangor; for instruction, Lieut. GEORGE I. BADEAUZ, Spooner.

To Milwaukee, Light Horse Squadron Armory, from Fort Riley, Major OTHO A. FIEDLER, Sheboygan; Lieuts. JEFFERY J. BROOK, ULRICH SENN, Milwaukee.

To Rockefeller Institute, for instruction in laboratory work, from Camp Travis, Lieut. RALPH R. GILCHRIST, Milwaukee.

To his home and honorably discharged on account of being physically disqualified for active service, Lieut. ARTHUR C. DANA, Fond du Lac.

To his home and honorably discharged, from Camp Doniphan, Lieut. HARRY E. MacLAUGHLIN, Waupaca.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

COLORADO

New Hospital.—Dr. Frank P. Van Denbergh, Greeley, has opened a Red Cross Hospital in that city with accommodation for twenty patients.

Base Hospital Accepted.—The medical personnel of Base Hospital No. 29, which has been formally accepted by the War Department, includes Major John W. Amesse, Denver, director of the unit; Major Edward F. Dean, Denver, chief of the surgical service; Major Gerald B. Webb, Colorado Springs, chief of the medical service; Capts. Lewis H. McKinnie, Colorado Springs; Cuthbert Powell, Denver; Clarence B. Ingraham, Jr., Denver; Oliver Lyons, Denver; Cyrus L. Pershing, Denver; William W. Williams, Denver; John R. Espey, Trinidad, and C. W. Poley, Denver, and Lieuts. L. Marshall Van Meter, Robert G. Packard, Lawrence K. Lunt, W. M. Barre, William C. Finnoff, Amos L. Beaghler, Ranulph Hudston, Harold G. Macomber, Arthur W. Stahl, Leonard G. Crosby and Wilson Cuthbert, all of Denver.

GEORGIA

County Physicians Organize.—The physicians of Chattooga County met at Summerville, November 2, and organized the Chattooga County Society, with an initial membership of fifteen. Dr. Benjamin F. Shamblin, Lyerly, was elected president; Dr. Willard B. Medlin, Summerville, vice president, and Dr. H. D. Brown, Lyerly, secretary-treasurer.

Health Proclamation.—The October issue of the *Health Bulletin* of the Georgia State Board of Health contains on its first page a proclamation by the governor on the subject of health, in which he advocates a return to the simpler and saner habits of life, and urges that all persons aid the constituted authorities by giving active cooperation to the state board of health in its effort to conserve the health of the people.

Personal.—Dr. Robert W. Todd, LaGrange, has been elected health commissioner for Tift County, succeeding Dr. D. C. Whittle, resigned to enter military service.——Dr. Andrew L. West, Athens, has become a member of the medical staff of the Macon Hospital, succeeding Dr. Francis Y. Herrington, Atlanta, resigned to enter military service.——Dr. Edward M. Green, clinical director of the Georgia State Sanatorium, Milledgeville, has resigned to accept the position of superintendent of the Pennsylvania State Hospital for the Insane, Harrisburg.——Dr. William A. Ellison, Milledgeville, physician to the State Reformatory, and health commissioner of Baldwin County, has resigned to enter the United States Public Health Service, and has been succeeded as health commissioner by Dr. George L. Chapman and as physician to the State Reformatory by Dr. Guy D. Compton.——Dr. Charles Wardell Stiles, U. S. P. H. S., Washington, D. C., has reported for duty to the Twenty-Eighth Division, Augusta, to take charge of the health situation in the zone contiguous to Camp Hancock.

ILLINOIS

In Memory of Gochnaur.—Memorial services were held in the First Presbyterian Church, Freeport, November 25, under the joint auspices of the church and Masonic fraternity in memory of Lieut. Orlando M. Gochnaur, M. R. C., who was killed in action while attached to the British Expeditionary Forces in France. A popular subscription has been appointed in Freeport for the erection of a monument for Dr. Gochnaur.

Personal.—Dr. Gustav F. Ruediger, director of the Hygienic Institute for La Salle, Peru and Oglesby, has resigned to become director of the State Hygienic Laboratory at the University of Nevada, Reno.——Lieut. Wallace A. Belsey, Belvidere, medical director with the British Forces, is reported to have been wounded.——Dr. Vera V. Norton, for four years resident physician of the Edward Sanatorium, Naperville, has been appointed one of the superintendents of the Cincinnati Tuberculosis Sanatorium.

Legal Opinions Concerning Sanatorium Tax Levies.—The attorney-general of Illinois has given an opinion to the State

Department of Public Health to the effect that under the Illinois sanatorium law counties which have made tax levies for sanatorium purposes, and which need the money now to proceed with their plans, may lawfully anticipate the 1918 spring tax collections with warrants drawn for immediate use. It has also been held, however, that counties which made their sanatorium levies in September cannot at any later meeting during the year increase the levy. Another holding is that where counties have made levies for sanatorium purposes, but have not sufficient funds to build a county sanatorium, such counties may pay out of the sanatorium fund the expenses of persons sent to sanatoriums in other counties of the state, but not outside the state.

Chicago

Fire at Medical Supply Depot.—A fire, presumably of accidental origin, destroyed the new warehouse of the medical supply depot at Fortieth and Federal streets, with a loss of about $100,000.

Women Physicians Entertain.—Sixty medical women of Chicago were guests of the Medical Women's Club of Chicago and the After Dinner Club at the College Club, December 12. A dinner and entertainment made up the program.

Dinner to Colonel Raymond.—A complimentary dinner was given by Major Daniel A. K. Steele, president of the Illinois Division, M. R. C., U. S. Army, in honor of Col. Henry I. Raymond, department surgeon, Central Department, December 12, at the Hotel La Salle.

Proceedings of the Institute of Medicine.—Volume I of the *Proceedings of the Institute of Medicine of Chicago,* a book of 168 pages, covering the year 1916-1917, has just appeared. It covers seven meetings and contains fourteen papers with discussions, and the obituaries and portraits of Dr. Henry B. Favill and Theodore B. Sachs. The roster of members lists 202.

Reporting Venereal Diseases.—The city ordinance of June 29, 1917, requires the reporting of venereal diseases to the board of health. In order to carry out the provisions of the ordinance the health department has prepared and mailed to all physicians within the city a postal card blank on which to report cases; a blank form of letter from one physician to another, to inform the latter that a patient treated by him has consulted the former, a form letter to report to the department of health that a patient has not reported to the physician and that ten days have passed since the time agreed on, and a pamphlet concerning venereal diseases for distribution to patients.

KANSAS

Typhoid Fever.—It is reported that there are 300 cases of typhoid fever in Eldorado, and that antityphoid inoculation has been given to 2,000 of the inhabitants.

Personal.—Dr. William S. Lindsay, Topeka, has qualified as medical examiner for the first district appeal board, succeeding Dr. Samuel J. Crumbine, secretary of the state board of health.——Dr. Albert C. Johnson, Kingman, coronor of Kingman County, has been appointed county physician, succeeding the late Dr. Newton C. Davis, Kingman.

IOWA

Personal.—Dr. Alexis N. Warren, Sioux City, sustained painful injuries, November 20, when his motor car was run into by another automobile. Dr. Warren is under treatment in the Samaritan Hospital.——County Physician Frank O. Burke of Scott County has resigned.

Hospital Opened.—The informal opening of the Iowa Congregational Hospital, Des Moines, took place, November 23. The hospital has just been completed at a cost of nearly $10,000. The date of the formal opening of the hospital is not yet fixed.

MASSACHUSETTS

Advisory Committee Appointed.—A committee of five physicians, consisting of Drs. Albert Evans, Boston, chairman; Dr. John T. Williams, Boston, secretary; Dr. Frank G. Wheatley, North Abington; Arthur A. Howard, Boston, and Dr. Harry Linenthal, Boston, has been appointed to cooperate with the industries in the work of protecting workers of the state against ill health, loss of time, accidents, sickness and death. One of the duties of this committee will be to see that the laws for protecting the health of workers are enforced in the state.

Personal.—Dr. Harry J. Hagerty has been appointed substitute ambulance surgeon in the Worcester police department, succeeding Dr. Robert J. Northridge, who has been made ambulance surgeon, vice Dr. Joseph A. Smith, resigned to enter military service.——Dr. Willard B. Howes, assistant superintendent of the Rutland State Sanatorium, has resigned to become school medical supervisor for the community health service at Framingham, and has been succeeded by Leon A. Alley, Boston.——Dr. Hiram L. Horsman, Worcester, has been appointed acting superintendent of the Grafton State Hospital, succeeding Dr. James V. May, Worcester, resigned to accept the position of superintendent of the Boston State Hospital.

Merger of Harvard and Technology School Forbidden.—The supreme court of Massachusetts has decided that Harvard University has no right to support the merger of the Lawrence Scientific School with the Massachusetts Institute of Technology from the Gordon McKay bequest, an arrangement which was put into effect some time ago, and under which Harvard abolished the Lawrence Scientific School. The decision is on the petition of Harvard to have the court ratify the agreement between the two institutions. In the opinion, written by Judge DeCourcy, it is said that Mr. McKay intended that not only the investment of the endowment fund, but the education which his endowment was to make possible, should be under the control and direction of the university, its government and administration. He selected as a trustee to carry out his purpose a great educational institution, one whose ability adequately to carry out his plans he was familiar with, and with whose historic name he desired to associate his own in perpetual memory. Harvard will now have to reestablish a school of applied science under its own administration.

MINNESOTA

Smallpox.—There were said to be forty-eight cases of smallpox in St. Paul, November 28.

Personal.—Dr. Carl J. Holman, Mankato, who suffered a fracture of three ribs and an injury of the lung in an automobile accident, recently, is reported to be doing well.

Medical Board Appointed.—Dr. Archibald MacLaren, St. Paul, has been appointed chairman, and Dr. Arthur S. Hamilton, Minneapolis, secretary of the Minnesota state committee on the organization and supervision of state medical advisory draft boards, and other members of the committee are Drs. William H. Magie, Duluth, Dr. John H. Adair, Owatonna, and Alfred E. Spalding, Luverne.

Social Hygiene Commission Appointed.—Governor Bernquist has appointed the following physicians as members of the bureau for disease control of the Minnesota Social Hygiene Commission: Drs. Richard O. Beard, Elexions T. Bell, Albert J. Shesley, William A. Jones and Leonard G. Rowntree, Minneapolis; Drs. Henry M. Bracken and Charles D. Freeman, St. Paul; Dr. Edward L. Tuohy, Duluth, and Dr. Charles H. Mayo, Rochester, and as a committee on education, Drs. Henry W. Cook and Samuel E. Sweitzer, Minneapolis.

MONTANA

Personal.—Dr. Ellis A. Johnston has resigned as city physician of Helena.——Dr. Sidney A. Cooney has been appointed a member of the board of health of Helena.

The Mineral County Leper.—The United States Public Health Service has notified the state health board that no federal action can be taken in the case of Senator O. J. Willett of Mineral County, who is suffering from leprosy. Senator Willett will be isolated in his own county at a location approved by the state board of health.

Scarlet Fever and Smallpox.—Scarlet fever is reported to be epidemic in Billings.——There are said to have been 102 cases of scarlet fever reported to the board of health of Helena since May 1. Of these, thirty-four patients are now under quarantine. The apex of the epidemic was in the middle of October, when there were sixty patients under quarantine.——Smallpox is reported to be prevalent in Corvallis, where more than forty patients are under treatment. ——The threatened epidemic of smallpox in Livingston is under control. There are now nine patients under quarantine and two suspected cases are under surveillance.

NEBRASKA

New Hospitals.—Mrs. William Glover, Aurora, has made an offer to the city council to turn over her home to the city for a hospital, on condition that it shall be made fireproof, shall be open to all citizens on equal terms, and subject to her approval. The house contains eleven rooms, is heated by hot water, and lighted by electricity.——The Glasgow General Hospital, Hastings, is now open and ready to receive patients.

Personal.—Charles R. Robel, manager of the Lord Lister Hospital, Omaha, was killed by the overturning of his automobile near Oakland, Iowa, November 30.——Dr. William S. Yager, Nebraska City, has been appointed physician for the School for the Blind, Nebraska City, succeeding Dr. Claude Watson, deceased.——Dr. Arthur C. Stokes, Omaha, has been appointed, by the Omaha Red Cross Chapter, director of the hospital unit which has recently been organized by the Surgeon-General.——Dr. Lawrence B. Pillsbury, assistant superintendent of the Lincoln State Hospital, has been appointed superintendent of that institution, succeeding Dr. Benjamin F. Williams.

NEW JERSEY

Personal.—Dr. Francis B. Husted, Salem, was painfully injured by the overturning of his car, November 20.——Dr. John R. Stevenson, Haddonfield, who sustained serious injuries in a fall, recently, is reported to be improving.

Physicians Win Suits.—In the case of Henry Pendl, who brought suit against Dr. Halvor L. Harley, Pleasantville, for $10,000 for the death of his son, claiming negligence on the part of the physician, the jury, November 21, returned a verdict in favor of Dr. Harley.——The jury in the case of Capt. William J. Condon, M. R. C., U. S. Army, New Brunswick, charged with the murder of John V. Piper, a Rutgers College student, returned a verdict of not guilty, October 27.

NEW YORK

State Association Meeting.—The Medical Society of the State of New York announces that its annual meeting will be held in Albany in the week beginning May 20, 1918.

Lobar Pneumonia Reportable.—According to the *Bulletin* published by the Buffalo Health Department, November 24, lobar pneumonia is declared a reportable disease, requiring quarantine.

Rockaway Physicians Organize.—The physicians of Rockaway have organized the Medical Association of Rockaway Beach, and elected the following officers: president, Dr. Frank P. Hatfield, and secretary, Dr. Abraham Goldberg.

Medical Staff for Home Defense Corps.—The following medical staff has been appointed by the Erie County Home Defense Committee: Major Earl P. Lothrop, and Capts. Almon H. Cooke, Frank B. Rasbach and Lawrence Hendee, all of Buffalo.

Personal.—Dr. Jason Parker has resigned as superintendent of the Jones General Hospital, Jamestown.——Lawrence S. Hill, physical director of the Albany public schools, has been elected president of the New York Association of Medical Inspectors and physical directors.——Dr. Walter M. Clark has succeeded Dr. Joseph N. B. Garlick as health officer of Schenectady.——Dr. Charles V. Patchin, who has been seriously ill at his home in Dansville, is reported to be improving.

Pneumonia Unusually Prevalent.—Dr. Hermann M. Biggs, state health commissioner, has issued a statement in which he predicts a high rate from pneumonia this winter. His prediction is based on the record of recent winters. In October there were 282 more deaths from this cause than in September, and 171 more than the average for October in the last five years. The importance of recognizing that pneumonia is a communicable disease and of acting in accordance with this fact is urged, and also that it is essential in guarding children against this disease that they be kept in the best state of nutrition and comfort. Figures published by the department, December 4, show that for the first week in December this year there were 249 cases reported as against 184 for the corresponding week of 1916 and 165 for the corresponding week of 1915. According to the city records the death rate from pneumonia is low among Germans, Russians and Hungarians; it is three and one-half times as high among Italian children as among children of German mothers, three times as high as among children of Russian, Austro-Hungarian or Irish mothers, and a little more than double that of American mothers. Attention is called to fatigue, chilling, overcrowding and the use of alcoholic beverages as factors favoring the development of the disease. The statistics show that the mortality from pneumonia among drinking men is twice what it is among abstainers.

New York City

Personal.—Dr. J. Ramsay Hunt has been appointed consulting neuropathologist to the Craig Colony for Epileptics, Sonyea, N. Y.——Dr. William H. Maxwell, superintendent of schools in Brooklyn, who has been seriously ill in Flushing Hospital, is reported to be convalescent.

New Day Camp for Tuberculosis.—Under the auspices of the Society for the Prevention and Relief of Tuberculosis, the Boat Committee formally opened a new day camp for the care of tuberculous patients, the "Manhattan," at the foot of East Ninetieth Street, December 6. Addresses were made by Health Commissioner Dr. Haven Emerson, Dr. Hermann M. Biggs, health commissioner of the state of New York, and Dr. Louis I. Harris.

Order Hospitals at Munition Works.—The subcommittee on industrial diseases, poisons and explosives of the Council on National Defense met at the Hotel McAlpin in New York, December 1, when it formulated recommendations for presentation to the Council on National Defense. The recommendations provide that all munition plants shall establish hospitals for the care of their employees, and restaurants in which the workers may eat under sanitary conditions. It is also recommended that the work in the plants be so regulated that the workers do not come in direct contact with nitro and amido compounds.

New York Academy of Medicine Elects.—The stated meeting of the New York Academy of Medicine, December 6, was the occasion of the annual election. The term of office of the president, Dr. Walter B. James, does not expire until Jan. 1, 1919. The officers elected were: vice president, Dr. John A. Hartwell; corresponding secretary, Dr. D. Bryson Delavan; treasurer, Dr. Seth M. Milliken; trustee, Dr. L. Emmett Holt; member of Committee on Admission, Dr. Godfrey R. Pisek, and member of Committee on Library, Dr. Herbert S. Carter.

OHIO

Insurance Committee Appointed.—The Ohio State Medical Association has appointed the following committee to cooperate with the State Health and Old Age Commission: Drs. Walter H. Snyder, Toledo; Otto P. Geier, Cincinnati, and Gilbert E. Robbins, Chillicothe.

Personal.—Dr. H. Wadsworth Dornan, Ashtabula, is reported to be seriously ill in St. Petersburg, Fla.——Dr. Oscar H. Sellenings, Columbus, now on duty with the American Red Cross in France, has begun a study of the milk situation in that country.——Dr. Harry E. Cover, Bantam, was thrown from his buggy in a runaway accident, November 19, fracturing his leg below the knee.——Dr. John C. Darby, Cleveland, recently suffered a slight cerebral hemorrhage, and is confined to the house.

Club Takes Action on Medical Corps.—The Exchange Club of Toledo at a recent meeting adopted resolutions, introduced by Dr. Charles M. Harpster, Toledo, urging its senators and congressmen to support the bill to be introduced in the coming session of Congress, which provides that the medical officers of the Army shall have the same rank that prevails in the Medical Corps of the Navy; that out of 10,000 medical officers in active service there shall be twenty-five major-generals, twenty-five brigadier-generals, 400 colonels, 800 lieutenant-colonels, 2,350 majors, 3,200 captains, and 3,200 first lieutenants; that medical officers shall be equal in rank and authority with officers of the line, and that these provisions shall apply both to the regular service and the Medical Reserve Corps.

PENNSYLVANIA

Health Insurance Commission.—Governor Brumbaugh, October 16, announced the appointment of a commission to study health insurance and report to the next legislature. The members are Hon. William Flinn, Pittsburgh; William Draper Lewis, Philadelphia, and Dr. John B. McAlister, Harrisburg.

Mütter Lecture.—The Mütter Lecture on surgical pathology for 1917 was delivered in Thomson Hall of the College of Physicians, December 14, by Dr. Chevalier Jackson, Philadelphia, on "Observation of the Pathology of Foreign Bodies in the Air and Food Passages, Based on the Observation of 628 Cases." The lecture was illustrated by specimens, lantern slides, roentgenograms and color drawings.

Personal.—Dr. James D. Kiefer, Mount Carmel, is ill with gastric ulcer.——Dr. Fulton R. Stotler, has resigned after twenty-eight years of service as a director of the Wilkinsburg Board of Education.——Dr. Samuel G. Dixon, who has been ill at the University Hospital, Philadelphia, for three months, left the institution, November 27, greatly improved in health.

——Dr. John L. Sagerson, Johnstown, who was injured in an automobile accident recently and was under treatment in the Mercy Hospital, is reported to be convalescent.——Dr. Carlton H. Davidson, New Salem, who is serving on the western front in France, was gassed by a German shell and was partially blinded for one week.

Smallpox.—During the last week in November there were sixty cases of smallpox in twelve counties in Pennsylvania. ——The number of cases at Blue Ball, Lancaster County, increased in two days from eleven to twenty-one cases. The state health commissioner has issued the following warning regarding smallpox: "The state should realize it now has a patriotic duty to perform in stamping out smallpox. Our agents throughout the state are competent and active men but they can do little if the public fails to do its part. The present smallpox epidemic in Clearfield County and surrounding neighborhood is directly due to the fact that a case of smallpox which came into the state from Ohio was secreted and the knowledge of it kept from the health authorities." ——The quarantine on the Pennsylvania Railroad Construction at Gallitzin, where nearly 100 men have been held for two months, was lifted, November 23.

Philadelphia

Hospital Campaign.—On the first of its ten-day campaign to raise $50,000, St. Timothy's Hospital obtained $30,538, over 60 per cent. of the amount desired.

Result of State Examination for Optometrists.—Under the new state optometry law the examination recently held at the Central High School showed that several hundred would fail to get licenses. A number of the applicants could neither read nor write English.

Personal.—Dr. Frank C. Hammond, Philadelphia, has been appointed a member of the board of health to serve during the absence in France of Dr. Alexander C. Abbott.——Dr. William W. Keen has declined the renomination of president of the American Philosophical Society, after serving ten years in that capacity.——Major Arthur C. Christie, M. R. C., Surgeon-General's Office, Washington, D. C., and Dr. George M. MacKee, New York, addressed the joint meeting of the Philadelphia County Medical Society and Philadelphia Roentgen-Ray Society at the College of Physicians Building, December 12.——Dr. Edward E. Montgomery addressed the Atlantic County Medical Society at the stated monthly meeting, held at the Chalfonte Hotel, Alantic City, December 14.

SOUTH DAKOTA

New Hospital.—The new Methodist Episcopal Hospital at Mitchell was dedicated, December 9. The building has cost about $100,000, and will accommodate more than 100 patients.

Personal.—Dr. Arthur J. Jackson, Lead, has been appointed a member of the State Board of Health and Medical Examiners, succeeding Dr. Felix E. Ashcroft, Deadwood, term expired.

New District Society Officers.—The Seventh District Medical Society held its annual meeting and banquet in Sioux Falls, December 3, and elected Dr. Joseph G. Parsons, Sioux Falls, president; Dr. George W. Bliss, Valley Springs, vice president, and Dr. Goldie E. Zimmerman, Sioux Falls, secretary.

VIRGINIA

Personal.—Dr. Edward W. Rawls, Churchland, has succeeded Dr. Sherwood Dix, Port Norfolk, as a member of the Norfolk County Board of Health.

Medical College Admits Women.—A report states that the faculty of the Medical College of Virginia of Richmond at a recent meeting voted to admit women students.

CANADA

Military Hospitals Under Army Medical Corps.—Final arrangements have been completed whereby the Canadian Military Hospitals Commission is handing over to the Canadian Army Medical Corps the care of all wounded and sick soldiers in Canada.

Hospital News.—A new military hospital is to be built in High Park, Toronto, where there are available 25 acres of land. It is to be constructed on the plan of the Ontario Military Hospital at Orpington, England. Accommodation will be provided for 1,000 beds, and buildings of four or five stories will be built in connection with an administration building. The hospital will cost about $300,000, and two months will be required to get the buildings in condition for the reception of patients.

Personal.—Capt. George Ewart Wilson, Toronto, who was with the University of Toronto Base Hospital at Saloniki, and lately in England, has returned to Toronto.——Col. Frederick W. Marlow, formerly A. D. M. S., Toronto Military District, has been ordered by the Militia Department of Canada to Halifax, where he will be engaged in caring for the injured in the recent disaster which has swept over that city.——So far as yet announced, Dr. Murdoch Chisholm, one of the leading physicians of Halifax, is the only physician of the city whose name is included in the list of those who lost their lives in the Halifax disaster.——Dr. Charles J. C. O. Hastings, M. O. H., Toronto, despatched three nurses immediately to help at Halifax, and another twenty-five nurses will leave in a day or two.

GENERAL

Once More a Warning.—The Journal has repeatedly warned its readers of a subscription swindle worked on physicians and others. The individual presents himself as a contestant for a prize in the form of a scholarship to be awarded by an educational association to the one obtaining the most subscriptions in a certain length of time. It is worked under different names; we have called attention to it as the National Educational Association, Cornell Educational Association, The United Students' Aid Society. The latest is the Advance Society of the University of Illinois, with a military angle. The solicitors, two well-dressed young men, represent themselves to be contestants for a scholarship in an Army school. May we again suggest that those who would avoid being swindled should avoid paying money to traveling men whom they do not personally know?

Peroral Endoscopists Organize.—November 1, the Clinical Association of Peroral Endoscopists was organized in Philadelphia. The objects of the society are "The study of diseases and accidents occurring in the respiratory and upper digestive tracts, of borderline conditions and their treatment, medical and surgical, by direct inspection." The association also aims to impress on the internist and general practitioner the value of bronchoscopy and esophagoscopy as diagnostic methods of precision, to make possible the accurate ocular study in the living subject of the pathologic condition of the esophagus and lungs. The officers of the association are as follows: president, Dr. Chevalier Jackson, Philadelphia; vice president, Dr. Hubert Arrowsmith, Brooklyn; secretary-treasurer, Dr. Henry L. Lynah, New York, and members of the executive committee, Drs. Wolff Freudenthal, New York, and Samuel Iglauer, Cincinnati.

FOREIGN

The Milk and Coal Card Plague.—The *Nederlandsch Tijdschrift* relates that an Amsterdam physician, complaining of the plague of certificates he is called on to fill out, states that eighty-nine requests for a milk certificate reached him in one mail. Each required investigation as to the reasons why the extra milk should be granted the applicant. He gave one man with stomach disease a certificate entitling him to sick benefit, and the man presented it to the coal control bureau and obtained 2 tons of coal on the strength of it—the first time that anthracite was deemed a stomachic.

Federation of Foundling Asylums in Italy.—A national gathering of the officials of the *brefotrofi,* the foundlings' asylums, of Italy was held recently at Rome. Steps were taken for a federation of these institutions throughout the country. Among the measures voted was an appeal to the government to extend to adopted children under 12 the financial aid now given to the other dependents of soldiers. The question of care of syphilitic infants, advisability of colonies for them and prophylaxis of infection of others were among the subjects discussed, as also the necessity for more effectual measures for research as to the paternity.

The Leipziger Verband.—According to the *Nederlandsch Tijdschrift,* the Leipziger Verband recently convened for the first time since the war began. Of the officials and representatives of the organization, seventy-four have perished. There are now 25,800 members. Hartmann is still the president, and he urged physicians to make every effort to get the sickness insurance societies to found diagnostic laboratories. The Verband voted to establish an old age pension bureau, also to sustain in every way the dispensaries that have been opened for diagnosis and advice, especially for venereal diseases, without giving treatment. The meeting also went on record as opposing the idea of the practice of medicine becoming a state department, saying that the medical profession is best practiced when the physician can advise the sick man as a free and independent consultant.

PARIS LETTER

Paris, Nov. 15, 1917.

The War

TREATMENT OF INFECTED WOUNDS WITH JAVEL WATER

At a recent meeting of the Académie des sciences, Dr. Cazin, formerly chief of the surgical clinic at the Hôtel Dieu, and Mlle. Krongold presented an interesting communication on this subject. They are of the opinion that the use of diluted Javel water in the treatment of infected wounds has been wrongly condemned as being irritating. As a matter of fact, Javel water, in sufficient dilution, is not irritating at all. Daufresne used a very strong solution, but Cazin uses a 15 per thousand solution, which does not have any deleterious effect on human skin, even when in contact with it for twenty-four hours. Histologic examination showed that skin so treated was absolutely normal. On the other hand, skin similarly treated for twenty-four hours with Dakin's solution, the hypochlorite solution of Daufresne, or a solution of Javel water containing the same amount of sodium hypochlorite as Daufresne's solution shows, on microscopic examination, complete destruction of the epidermis and of the papillary layer as well as maceration and partial disintegration of the underlying subdermal fascia. Cazin and Krongold having confirmed Daufresne's findings with the use of a 50 cg. per cent. hypochlorite solution, used a solution containing 15 gm. of Javel water to the liter of water, that is, 0.042 gm. per cent. of sodium hypochlorite, or twelve times less than either Dakin's or Daufresne's solution. They have treated with their solution, at the Messimy hospital, 510 cases of infected wounds, including 155 compound fractures, 286 deep wounds of the soft parts, usually with extensive lesions, 44 amputations made in the fighting zone and suppurating after operation, and 25 cases of severe multiple wounds of the soft parts. Of these 510 patients, only three died, one from tetanus, and one from a severe icterus; two amputations were made because of extension of the lesion, not because of sepsis; 507 patients, all with severe cases, were cured. The 15 per thousand solution of Javel water has a greater bactericidal power than Dakin's solution and is less irritating, the caustic properties of the latter being due to its greater sodium hypochlorite content.

FRENCH BASE HOSPITALS IN RUSSIA

As stated in a previous letter, three military medical-surgical units were sent to Russia to be utilized by our allies in three sections of the country as hospital centers. M. Justin Godart, undersecretary of state for the army medical department, has been informed that after having overcome great difficulties, these units are now in full operation. After three months of methodical [illegible] have been opened in Ourmiah, Tiflis an[illegible] ambulances have been sent to the front, and are giving very good service under the direction of Medical Inspector Cresson.

A MILK CARD FOR CHILDREN AND THE SICK

Following a conference between the prefect of the Seine and the dairy association, held to provide measures to insure a sufficient milk supply for infants and the sick, it was decided to issue a milk card for their benefit. According to the measures adopted, families having children less than 3 years of age, or sick members who are restricted to a milk diet, will register with some milkman of their choice, and he will give them a special card to be detached from a stub book of cards. This card the recipients must have endorsed by the mayor of their arrondissement after having established their right to such a card. The signature of the physician who gave the medical certificate must be verified by the milk dealer or the mayor. The card issued to the sick is valid for only three months, but may be renewed, if necessary.

ESTABLISHMENT OF A CENTRAL FOOD BUREAU

The food commissioner has established a central bureau or office at which he may be consulted and from which information will be disseminated on the proper methods to be adopted to facilitate the supplying of cooperative municipal organizations or associations and of purveyors of foods of prime necessity. The bureau will combat especially the high prices in large towns, and strive to balance demand and supply. The bureau will supervise the distribution of supplies, both domestic and foreign, according to the needs of the people.

The "Maison d'Amérique" (America Building)

M. Lopez Lomba, the consul general of Uruguay at Paris, recently informed the Geographical Society that certain individuals have agreed to his project for creating a Pan-Atlantic Union, having for its object the founding of a "Maison d'Amérique" in Paris and of "Maisons de France" in the principal cities of the western hemisphere. The "Maison d'Amérique" will be the center for the development of commercial, financial, intellectual and social relations between American countries and between these and western Europe. The scheme includes a general information and propaganda bureau, an industrial exhibit, an American library and museum, a tourist bureau, a society, a journal, an American University, a home for students, a section for welfare work and social defense, courts, lectures, expositions, congresses, etc. M. Lomba is convinced that he will receive the support of interested states and particularly of the Pan-American Union. The meeting adopted a resolution approving this project as outlined.

LONDON LETTER

London, Nov. 13, 1917.

The War

NEW FOOD RATIONS

Sir Arthur Yapp, director of food economy, has announced a new scale of voluntary rations, which are as follows:

	Weekly Ration Lb.	Weekly Ration Oz.
Bread:		
Men on heavy industrial work or on agricultural work	8	0
Men on ordinary industrial or other manual work	7	0
Men unoccupied or on sedentary work	4	8
Women on heavy industrial work or on agricultural work	5	0
Women on ordinary industrial work or in domestic service	4	0
Women unoccupied or on sedentary work	3	8
Other Foods (for all adults):		
Cereals other than bread		12
Meat	2	0
Butter, margarin, lard, oils and fats		10
Sugar		8
Children:		
Children to receive "reasonable" rations, no definite scale being laid down.		
The scale laid down by Lord Devonport, the previous food controller, last winter was:		
Bread	4	
(or flour for bread making)	3	
Meat	2	8
Sugar		12*

*Afterward reduced to 8 ounces.

The new scale differs in several respects from the old one. The former food controller confined himself to rationing bread, meat and sugar, whereas Sir Arthur Yapp adds (1) all cereals other than bread, and (2) butter, margarin, lard, oils and fats. While Lord Devonport recognized the wide differences between reasonable food requirements of, say, men employed in hard manual work, men engaged in sedentary occupations, women similarly employed, and children of various ages, his scale was based on a flat rate for each individual, without discrimination as to sex, occupation or age.

The "bread" rations include all flour, whether used for bread or for cooking. Flour may be taken instead of bread at the rate of three-fourths pounds of flour for every pound of bread. The "other cereal" rations include oatmeal, rice, tapioca, sago, barley meal, corn flour, maize meal, dried peas, beans and lentils, and all cereal products except bread and flour. The weight given is the weight of the dry article as bought. If the full bread ration is not used, the amount saved can be taken in other cereals at the rate of three-fourths pounds of cereals for every pound of bread saved. The "meat" rations include the average amount of bone, which may be taken as one quarter of the weight of the actual meat. Any parts of meat (such as rump steak, bacon or suet) which are bought without bone must count for one quarter more than their actual weight. On the other hand, any bone in excess of a quarter of the actual meat bought may be deducted. Poultry and rabbits may be counted at half their actual weight. The meat rations include suet.

A MINISTRY OF HEALTH

Speaking on this subject at the Royal Institute of Public Health, Mr. A. L. Fisher, the minister of education, said that the time now seemed to have come to consider whether all the agencies existing in the country should be combined into a more effective and economical system for promoting public health. A child came into the world under the egis of the Central Midwives Board. A month or two later he received the care, if he received any at all, of a voluntary association, which might or might not be subsidized by the

Board of Education or by the Local Government Board. About the age of 3 the child might proceed to an elementary school, and from 3 to 14 might receive his education there. During that period he was under the medical supervision of the school medical service, which in turn was controlled by the local education authorities and the Board of Education. From 14 to 16 the child did not seem to be under any special public health control. At 16 the child passed under the control of the Insurance Commission. Children who were engaged in manufactures were medically supervised by the Factory Department of the Home Office, unless they happened to be engaged in the manufacture of munitions, in which case they passed under the control of the minister of munitions, if they were not disabled by the war, in which case they were the prey of the Local Pensions Committee. Of course, if the child happened to be mentally defective, he passed under another system of control. If he had the misfortune to be a pauper he became the object of the solicitude of the Poor Law authorities. Thus the child might pass under a very large number of possible public health authorities.

Major Astor also read a paper. He referred to the administrative chaos which resulted from the responsibility for health and welfare being divided between seven central bodies, and many conflicting and overlapping local ones. The first thing required was a central department, and the second was the disentangling and straightening out of the spheres and functions of the 1,800 sanitary authorities of the 630 boards of guardians, of the 238 local insurance committees, of the 318 local education authorities, and of the 320 new pensions committees. Before the war he presided over an informal committee consisting partly of members of Parliament, and partly of practical medical administrators. They investigated alternative schemes of reconstruction. At first they favored the creation of a new ministry, but soon they became convinced that it would be easier, quicker and probably more effective at the start to build on an existing department. The committee next examined the machinery then in existence, and decided that of the various ministries only two needed to be seriously considered as possible nuclei for a health ministry—the Insurance Commission and the Local Government Board. At first the committee inclined to the Insurance Commission as the department on which to build, but was driven to the conclusion that at its inception, at all events, the Local Government Board should be the center to which the services connected with prevention, treatment and inspection should be gradually transferred from the numerous departments now responsible for their provision. If they were to carry out Lord Rhondda's ideal and save 1,000—or even 500—baby lives per week, they must have a health minister, and not three ministers, or even two ministers.

THE PREMIER'S TRIBUTE TO THE ARMY MEDICAL SERVICE

In proposing in Parliament a vote of thanks to the British armies at the conclusion of three years of war, Mr. Lloyd George paid a tribute to the medical service, which he said had never shown greater courage, knowledge and experience. Great consultants had given up princely incomes and volunteered for this service. Wounds had been cured which before the war were regarded as fatal. As an illustration of the services rendered in saving life, he mentioned that in the South African War 50,000 men had died of typhoid. In France, out of our gigantic army, during the whole three years of the war only 3,000 had fallen victims to this disease. The medical profession had suffered. Hundreds had been killed and many more hundreds wounded. Thanks were also due to the women, our trained and untrained nurses, whose tenderness for the wounded had earned thanks from the lips of hundreds of thousands of poor men whose lives had been saved and who had been spared much suffering through their tender ministrations. They had not escaped perils. Many had been killed by shell fire. Many of them had been drowned in hospital ships, sunk with the sign of the cross on them.

In the House of Lords, Earl Curzon proposed a similar motion. He said that when war broke out the Royal Army Medical Corps had 3,168 officers and 16,330 men of other ranks. There were at the present time nearly 14,000 officers and 125,000 of other ranks. The health of the army had been better than that of the civilian population at home. He also mentioned the work of the nurses, not only in the hospitals behind the line, but also in the casualty clearing stations only just behind the front. Seven had been drowned by submarine action, and several others had been killed by enemy bombs on hospitals. The name of one had been rendered immortal by her martyrdom.

Marriages

Frank Wyman Lamb, M.D., Akiak, Alaska, physician in charge of the Government Hospital, U. S. Bureau of Education, to Miss Rose May Wynne of Norton, Kan., at Akiak, October 13.

Lieut. Frederick Christopher, M. R. C., U. S. Army, Mobile Surgical Unit, to Miss Madeline Smith, both of Chicago, December 1.

George Edmund Dearden Desaulniers, M.D., Montreal, Que., to Lucy Jane O'Connell, M.D., of Lewiston, Me., November 23.

Asst. Surg. Frederick Talmadge Lau, U. S. N. R. F., Detroit, to Miss Amy Carleton Leefe of New York City, December 4.

Paul Butler Jenkins, M.D., New York City, to Miss Alma Louise Wells of Binghamton, N. Y., November 19.

Walter Lee Boswell, M.D., Macon, Tenn., to Miss Blarnae La Vleet Crawford of Rossville, Tenn., October 29.

Francis E. Drumheller, M.D., to Miss Ella Kirkpatrick, both of Sunbury, Pa., in Philadelphia, recently.

Alexander Emmett Turman, M.D., to Mrs. Ruby Thomas Storrs, both of Richmond, Va., December 5.

Frank Kingsley Dutton, M.D., to Miss Huldah Carlson, both of Springfield, Mass., December 1.

Fred Miller Drennan, M.D., Chicago, to Miss Esther Olive Clay of Quincy, Ohio, recently.

Deaths

Oscar M. Leiser, M.D., New York City; College of Physicians and Surgeons in the City of New York, 1896; assistant director of the Bureau of Health of New York; died suddenly, December 11. He was a Fellow of the American Medical Association and of the New York Academy of Medicine. Dr. Leiser was a powerful propagandist against charlatanry and fraud, and had been attached to the bureau since its organization. He had acted as the medical expert of the health department in trials of cases against quacks and medical fakers for several years, and not a case in which he had testified was decided by the courts against the department. Dr. Leiser was hated and feared by all the "patent medicine" fakers, for he was outspoken and fearless in his denunciation of their methods. In his connection with the department of health, which had continued for nearly twenty years, he had served in practically every medical branch of the department. Dr. Leiser was a man of charming personality, able and devoted.

Samuel Parker Cottrell, M.D., Newport, R. I.; Jefferson Medical College, 1882; aged 57; a member of the Rhode Island Medical Society; for several years assistant surgeon in the Massachusetts Women's Hospital, Boston; lecturer in Tufts Medical College, Boston; professor of children's diseases in the St. Paul Medical College, and later chief surgeon of the Boston Emergency Hospital; surgeon of volunteers during the war with Spain; a member of the Newport Board of Health; died in Providence, R. I., December 1.

Charles Willard Howard, M.D., Shoreham, Vt.; University of Vermont, Burlington, 1874; aged 72; formerly a Fellow of the American Medical Association; a member and once vice president of the Vermont State Medical Society, and president of the Addison County Medical Society; for fourteen years superintendent of schools; for three years a member of the county board of education, and since 1881 town clerk; in 1908 representative in the legislature from the town of Shoreham; died at his home, December 1.

William Wayne Owens, M.D., Savannah, Ga.; University of Virginia, Charlottesville, 1885; aged 54; a Fellow of the American Medical Association; a member of the Society of Southern Railway Surgeons; major and surgeon of the First Cavalry, Ga. N. G.; a member of the staff of the Savannah Hospital; a member of the state board of health; local surgeon of the Southern Railway; at one time a member of the city council of Savannah; died suddenly in a store in Savannah, November 23.

David Adams Spear, M.D., Burlington, N. J.; University of Virginia, Charlottesville, 1897; aged 39; a member of the

Medical Society of Virginia, and a specialist on diseases of the eye, ear, nose and throat; who formerly conducted a sanatorium at Albuquerque, N. M.; while driving his automobile over a grade crossing between Burlington and Florence, November 25, was struck by a freight train, and died from his injuries while being conveyed to the Riverside Hospital.

Samuel E. Lewis, M.D., Washington, D. C.; Medical College of Virginia, Richmond, 1864; aged 79; a Fellow of the American Medical Association; first vice president and later president of the Association of Naval Officers of the Army and Navy of the Confederacy; assistant surgeon in the Confederate Service, and in command of the Chimborazo Hospital, Richmond, Va., during the Civil War; from 1868 to 1884 a pharmacist; died in his apartment, November 17.

Samuel S. Boots, M.D., Greenfield, Ind.; Eclectic Medical Institute, Cincinnati, 1870; aged 68; for ten years a member and for two years president of the Indiana State Board of Health; president of the Greenfield Banking Company; for twelve years a member of the faculty of the Indiana Eclectic Medical [illegible]; formerly editor and publisher of the [illegible]l *Investigator* and *Greenfield Herald;* died at his home, November 30, from pneumonia.

Ami Jacques Magnin, M.D., Paris, France; Bellevue Hospital Medical College, 1881; Faculté de Médecine de Paris, 1886; aged 59; formerly secretary of the surgical section of the New York Academy of Medicine; and a member of the staff of the French Hospital, Bellevue Hospital, and Vanderbilt Clinic, New York City; chief surgeon of the American Hospital, Neuilly, near Paris; an officer of the Legion of Honor; died suddenly at his home, November 25.

Zephaniah Kerr Wiley, M.D., Baltimore; College of Physicians and Surgeons, Baltimore, 1875; aged 74; a Confederate veteran; lecturer in anatomy in Baltimore Medical College, and one of the founders; later professor of anatomy, professor of obstetrics and dean of Baltimore University; who was thrown from a street car while making a professional call about a month ago; died from his injuries in the Biedler-Sellman Sanatorium, Baltimore, November 25.

Samuel A. Johnson, M.D., Springfield, Mo.; Kentucky School of Medicine, Louisville, 1889; aged 54; a Fellow of the American Medical Association; superintendent of the Johnson Sanitarium, Springfield; formerly assistant superintendent of State Hospital No. 3, Nevada; was attacked with an axe by an epileptic patient in the yard of the hospital, November 24, sustaining injuries from which he died on the following day.

John Jacob Ott, M.D., Pleasant Valley, Pa.; University of Pennsylvania, Philadelphia, 1874; aged 66; a member of the Medical Society of the State of Pennsylvania; also a pharmacist; vice president and director of the C. and E. Railroad; director of the Quakertown Trust Company; and one of the originators and directors of the Globe Mutual Life Stock Insurance Company; died at his home, November 22.

Albert H. Steinbrecher, M.D., Detroit; Detroit Medical College, 1881; aged 59; a Fellow of the American Medical Association; professor of practice of medicine and clinical medicine in the Detroit College of Medicine and Surgery; a member of the staff of St. Mary's Hospital and the Womans' Hospital and Infant Home, Detroit; died at his home in Arden Park, Detroit, November 25, from heart disease.

Roland C. Shear, M.D., Mount Gilead, Ohio; Starling Medical College, Columbus, Ohio, 1891; aged 50; a member of the Ohio State Medical Association; a specialist in diseases of the eye, ear, nose and throat; for two terms coroner of Morrow County, and later deputy probate judge and probate judge; died in a hospital in Cleveland, November 26, two days after an operation for appendicitis.

John Taylor Jones, M.D., Grass Valley, Calif.; Cooper Medical College, San Francisco, 1898; aged 42; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of California; died at his home, November 19, from spinal injuries sustained in a dive in a swimming tank about ten years before.

Charles Orvis Goulding, M.D., Pittsburgh; Bellevue Hospital Medical College, 1887; aged 58; a Fellow of the American Medical Association, and a charter member of the Pittsburgh Academy of Medicine; associate professor of clinical medicine in the University of Pittsburgh; died at his home, November 27, from pneumonia.

Frederick Page Ransom, M.D., Pittsburgh; Jefferson Medical College, 1904; aged 37; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; assistant on the surgical staff of the Allegheny General Hospital; died at his home in Pittsburgh, November 19.

John William Baker, M.D., Granite City, Ill.; St. Louis University, 1911; aged 31; formerly a Fellow of the American Medical Association; a member of the Illinois State Medical Society; while driving his automobile over a grade crossing at Madison, Ill., November 30, was struck by a Wabash passenger train, and died two hours later at St. Elizabeth's Hospital, Granite City.

William Henry Keim, M.D., Philadelphia; Hahnemann Medical College, Philadelphia, 1871; aged 74; president and executive officer of St. Luke's Homeopathic Hospital, Philadelphia; and once president of the State Homeopathic Medical Society; demonstrator of surgery in his alma mater; died at his home, November 23.

Lieut. Sigmund Deutsch, M. R. C., U. S. Army, New York City; College of Physicians and Surgeons in the City of New York, 1892; aged 41; a Fellow of the American Medical Association; visiting physician to the German Hospital and Vanderbilt Clinic; died at his home, November 29, from cerebral hemorrhage.

Edward William Karrmann, M.D., Cheshire, Conn.; New York University, New York City, 1891; aged 65; a Fellow of the American Medical Association; acting assistant surgeon, U. S. Army in 1889; while driving over a grade crossing in Cheshire, November 28, was struck by a trolley car and instantly killed.

Olaf T. Melde, M.D., Spokane, Wash.; Physio-Medical College of Indiana, Indianapolis, 1890; aged 48; formerly a member of the Washington State Medical Association; who had been taking a postgraduate course at the Chicago Eye and Ear Hospital; died suddenly in that institution, November 19, from heart disease.

Capt. Augustin de Yterbide Green, M. R. C., U. S. Army, Prosser, Wash.; Georgetown University, Washington, D. C., 1901; aged 42; a Fellow of the American Medical Association; on duty at Camp Lewis, American Lake, Wash.; died in the cantonment base hospital, Camp Lewis, November 25, from pneumonia.

Frank Loring Sargeant, M.D., Victoria, Texas; College of Physicians and Surgeons, Chicago, 1900; aged 45; formerly a Fellow of the American Medical Association; a member of the State Medical Association of Texas; a specialist on diseases of the eye, ear, nose and throat; died at his home, November 11.

Jules F. Vallé, M.D., St. Louis; Washington University, St. Louis, 1885; aged 58; a Fellow of the American Medical Association; a member of the staff of St. Luke's Hospital; physician to the Missouri School for the Blind, St. Louis; a director of several iron companies; died at his home, November 24.

Rudolph F. Schaefer, M.D., Oklahoma City; Washington University, St. Louis, 1892; aged 51; formerly a member of the Oklahoma State Medical Association, and professor of obstetrics and diseases of women in Epworth College, Oklahoma City; died at his home, November 9, from diabetes.

James Mills, M.D., Janesville, Wis.; Northwestern University Medical School, 1883; aged 65; formerly a Fellow of the American Medical Association; a specialist on diseases of the eye, ear, nose and throat; jumped from a bridge in Janesville, into Rock River, November 18, and was drowned.

Abram Leander Sherick, M.D., Ashland, Ohio; Bellevue Hospital Medical College, 1880; aged 61; formerly a Fellow of the American Medical Association; a member of the Ohio State Medical Association; a specialist in surgery; died at his home, November 18, from disease of the stomach.

Francis Anderson Lyman, M.D., Waimea, Kauai, T. H.; Rush Medical College, 1889; aged 54; a Fellow of the American Medical Association; for nine years superintendent of the Wisconsin State Hospital, Madison; since 1913 a practitioner of Hawaii; died at his home, November 4.

Claire W. Murphy, M.D., Los Angeles; University of California, Los Angeles, 1891; aged 47; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of California; instructor in anatomy in his alma mater; died at his home, November 24.

Jonathan Milton Wyland, M.D., Moline, Ill.; State University of Iowa, Iowa City, 1886; aged 59; president of the Moline Foundry Company, who had been ill for two years with spinal disease, due to an accident; died at his home, November 29, four weeks after a surgical operation.

Joseph Lorenzo Brunet, M.D., New Orleans; Tulane University, New Orleans, 1898; aged 61; for many years a practitioner of Covington, La., formerly a member of the Louisiana State Medical Association; died at his home, November 19, from heart disease.

Waldo Fitch Sawyer, M.D., Vineland, N. J.; Jefferson Medical College, 1890; aged 52; a member of the Medical Society of New Jersey; once mayor, and for one term coroner of Cumberland County; died at his home, November 17, from pneumonia.

Hans Kudlich, M.D., Hoboken, N. J.; University of Zurich, Switzerland, 1853; aged 94; one of the last survivors of the Revolution of 1848; who retired from practice thirty years ago; died at his home, November 10, from acute bronchitis.

Thomas McKaig Wall, M.D., Osceola, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1867; aged 73; formerly a member of the Iowa State Medical Society; a veteran of the Civil War; died at his home, November 18.

Silas Pinckney Holbrook, M.D., East Douglas, Mass.; University of Pennsylvania, Philadelphia, 1862; aged 80; a member and councillor of the Massachusetts Medical Society; died in Farnumsville, Mass., October 2.

Joseph Mark Malatesta, M.D., Philadelphia; Jefferson Medical College, 1886; aged 58; also a graduate in pharmacy; for a time instructor in dermatology in his alma mater; died at his home, November 22, from disease of the kidney.

William T. Griffis, M.D., Fountain City, Ind.; Eclectic Medical Institute, Cincinnati, 1871; aged 70; formerly a member of the Indiana State Medical Association; died at his home, about November 20.

John D. Kaple, M.D., Ogdensburg, N. Y.; Cleveland University of Medicine and Surgery, 1896; formerly a member of the Medical Society of the State of New York; died at his home, November 17.

William Alexander Armstrong, M.D., Philadelphia; Philadelphia University of Medicine and Surgery, 1861; aged 77; died at the home of his son in Philadelphia, November 22, from heart disease.

Albert A. Norris, M.D., Philadelphia; Hahnemann Medical College, Philadelphia, 1887; aged 63; for nineteen years chief clerk at the Philadelphia Mint; died at his home, November 24, from nephritis.

Joseph H. H. Reser, M.D., Conway, Mo.; Ensworth Medical College, St. Joseph, Mo., 1893; aged 67; a member of the Missouri State Medical Association; died at his home, November 8.

William H. Cole, M.D., Kewanee, Ill.; Long Island College Hospital, Brooklyn, 1873; aged 79; a member of the Illinois State Medical Society; died at his home, November 29.

George A. Bachman, M.D., Rochester, N. Y.; New York Homeopathic Medical College, New York City, 1892; aged 49; died at his home, November 21, from heart disease.

Samuel Andrew O'Neal, M.D., Henderson, Ky.; Meharry Medical College, Nashville, Tenn., 1888; aged 55; a colored practitioner; died, November 21, from influenza.

James McQuillen, M.D., Superior, Wis.; McGill University, Montreal, 1874; aged 67; a Fellow of the American Medical Association; died at his home, November 19.

STRANDGARD'S T. B. MEDICINE

Exploiting the Tuberculous Canadian Soldier

The resident physician of a Canadian sanatorium devoted exclusively to the scientific treatment of tuberculosis writes:

> "The enclosed leaflet and letter from the Dr. Strandgard's Medicine Co. of Toronto, Can., is being sent in a plain envelope, marked 'personal' to a number of returned Canadian officers who are patients in this institution. If you have any information regarding this 'cure' or the company, your Canadian readers would appreciate its publication in The Journal."

The letter enclosed was on the stationery of the "Dr. Strandgard's Medicine Co." It was addressed to a man suffering from tuberculosis—a man who had been stricken with this disease while in the service of his country. The "patent medicine" concern states in its letter:

> "Our T. B. medicine is a specific for the complaint of which we have been informed you are suffering . . ."

This cruel falsehood is followed up by the statement that the stuff is a "high-class scientific preparation endorsed by physicians" which, previous to being put on the market, was "used with wonderful success in private practice." Further:

> "Dr. Strandgard has been awarded gold medals at four international exhibitions in Europe for his medicines."

Just what was the nature of these exhibitions, we do not know; possibly they were the same sort of international "expositions" that were exposed in The Journal[1] about three years ago whose "gold medals" meant no more than that the exploiter has paid a specified sum as a guaranty that he would receive an "award." The letter to the consumptive continues:

> "Of course, one bottle will not improve your health owing to the nature of your case, but after three bottles you will derive considerable benefit and will continue to take it until you feel you are restored to normal health. Kindly write us informing us of your permission to forward three bottles. We are agreeable to send them on condition that you do not pay for them unless you are satisfied with the progress you have made . . ."

This appeal is typical of "consumption cure" humbugs. Throughout the entire advertising matter the claim is made by inference that the remedy will cure consumption. None knows better than the trader in a fake consumption cure how easy it is to persuade the consumptive during the first few weeks of any new and mysterious "treatment" that he has been benefited. Time and again it has been shown that such concerns run no risk in offering to send limited amounts of their nostrums to the victims on a basis of "no pay unless satisfied."

The booklet sent by the Strandgard concern states that the preparation was originated by one "Chevalier Dr. Jean F. Strandgard, K. V. V. P." Some prospective purchasers are obtained by offering a free bottle of the nostrum to any one who will furnish "fifteen (15) names and addresses of persons genuinely suffering either from Consumption—Tuberculosis, Asthma, Bronchitis, Catarrh, Weak Lungs, Pleurisy, Pneumonia, Coughs, Colds, or any disease of the respiratory organs." No information is given regarding its composition, although a pretense is made of doing so by stating that it is:

> ". . . from Nature's Garden being made from pure Essences, Infusions, Extracts and healing medicinal virtues of rare barks, roots and herbs."

It contains alcohol—also typical of the fake "consumption cure"—and the usual excuse is offered that this drug is not present "in any larger quantity than is absolutely necessary" to dissolve one of the alleged constituents. It is to be taken six times a day in two-dram doses. The sixteen ounce bottle thus lasts about ten and one-half days. This means that the three bottles which they offer to send without payment in advance would last the victim about one month. Every physician who has treated consumptives knows that such patients after taking any nostrum—especially one containing alcohol or bitters—for three or four weeks under the glamour of the claims common to quackery, insist that they are "feeling better."

---

[1] Reprinted, with addition, in the pamphlet, "Some Quasi-Medical Institutions," published by the American Medical Association; price 10 cents.

The booklet contains several testimonials; most of them from laymen. Not one of the testimonials declares that the stuff has cured a case of pulmonary tuberculosis or even that it is of value in such cases. Most of them refer to its alleged use in asthma and bronchitis. One is from an alleged sufferer from spinal tuberculosis who claims to have been benefited, although not cured. Two of the testimonials purport to be from medical men—A. H. Paget, M.D., and P. B. Wood, M.D.—both of whom, the booklet claims, are "Members of the College of Physicians and Surgeons of Ontario." While neither of these physicians' testimonials declare that the stuff is a cure or even a treatment for consumption, the evident intent of the booklet is to make the consumptive so believe. Whether the giving of these testimonials indicates a failure to recognize professional responsibility or a mere lack of common sense, we do not know; the solution of such questions may safely be left to the organization to which these men are said to belong.

A fake "consumption cure" is vicious enough under any circumstances. Every physician who has treated consumptives knows how difficult it is to persuade the sufferer that his chance for recovery rests not on medicine but on hygienic and dietetic measures. It is a human failing to believe that every disease may be cured by taking something out of a bottle, and the consumptive is particularly susceptible to the wiles of the "patent medicine" faker. But, if under normal conditions and exploited to civilian consumptives the "consumption cure" business is a cruel deceit, what shall be said of the concerns which seek as victims those men who have acquired tuberculosis in the service of their country? The human carrion that robs the wounded on the field of battle at least takes his life in his hands in so doing; not so the "consumption cure" quack who plies his trade on the invalided soldier.

Anthrax.—This disease, as shown by the Public Health Bulletin of Massachusetts for October, has become increasingly prevalent in the state since the beginning of the war. The cases varied between six and eleven for the years 1908 to and including 1915, when they reached the latter figure. In 1916 the number was thirty-one and for the first nine months of 1917 the number was thirty-nine. The increase has been coincident with the increased shipment of hides from foreign countries whose status with regard to the incidence of anthrax is not well known, the demand for leather having forced manufacturers to seek new sources of supply. In 1917, six of the thirty-nine reported cases were fatal. There was one case of pulmonary anthrax; the remainder were external The pulmonary case and thirty-four of the others resulted from the handling of hides, three from the handling of hair and one from handling wool. Accurate diagnosis depends on the bacterial findings. It is said that English investigators have reported cases of anthrax simulating cerebrospinal meningitis, the diagnosis not being established until the anthrax bacilli were demonstrated in the spinal fluid. The United States Bureau of Animal Industry recommends for the prevention of infection that hides be immersed for not less than forty-eight hours in a 1:1,000 solution of mercuric chlorid, or for a like period in a 10 per cent. salt solution containing not less than 2 per cent. of hydrochloric acid. The British Local Government Board directs that in the steam disinfection of hair, cases or bales should be opened and the bundles removed and most of the strings cut unless the temperature inside the steam apparatus is maintained at 230 F. for half an hour.

Correspondence

THE CARREL-DAKIN TREATMENT

A Reply to Dr. Bevan by Dr. Joseph C. Bloodgood

To the Editor:—I cannot agree with my friend and colleague, Dr. Arthur Dean Bevan, but I am rather inclined to the view that his open letter to Dr. Welch (THE JOURNAL, Nov. 17, 1917, p. 1727) will do good. A fair controversy leads to the crystallization of the opposing opinions, and often hastens the proper solution of the problem.

I cannot agree with Dr. Bevan that Carrel's method is against the views of surgical pathology and wound repair. I confess, I am somewhat confused myself as to what the real surgical pathology of wound repair is.

Bevan speaks of surgical pathology resting on the work of such men as Lister, Paget, Billroth, Fenger and Senn. Senn's chief work was in the surgical pathology of tumors, and his experimental work chiefly in intestinal suture, fracture of the neck of the femur, and pancreatitis. Fenger's pathologic work began at the necropsy table and continued as that of an operating surgeon interested in the pathology of the diseases that he attempted to cure by operation. Neither was particularly interested in wound repair and wound infection, and, as most of us today, had little or no experience with wounds of the character seen in this war. Billroth, perhaps the greatest of all surgical pathologists, missed a great opportunity in his military experience to establish the noninterference methods in the old type of perforating bullet wound.

As I read Lister, I am impressed with the conclusion that his observations and results very strongly suggest the great value of an antiseptic. In all of Lister's experience he was never confronted with wound problems such as confront us in this war. Schede's work on blood clot in osteomyelitis is evidence that an antiseptic can sterilize a wound. In conversation, Dr. Halsted, professor of surgery at Johns Hopkins University, fully agreed with me as to the statements I am now making. I know of no surgeon of his time in America who has devoted more attention to the problems of wound healing and the treatment of infected wounds than has Halsted. His early contributions to the treatment of joint infections prove this. Halsted looks on Carrel's work as most scientific and as the greatest contribution to wound treatment in this war.

Dr. Bevan is of the opinion that it was a serious mistake for the government Medical Service to adopt the Carrel treatment and to force "a complicated, time-consuming, expensive plan" on our Medical Service. I cannot agree with Dr. Bevan. In the first place, I do not know that the Surgeon-General has "adopted" the Carrel method. After rereading Carrel's book a number of times, with frequent visits to his experimental hospital in New York, and after using his method, I am of the opinion that the Surgeon-General has given the surgeons of this country the best opportunity as yet ever offered them for the study of wound repair and wound treatment by ordering officers of the Medical Corps to take a course of instruction in the Rockefeller War Hospital; the courses given in Philadelphia will also be of inestimable value.

As Piper of Philadelphia said after his experience in the hospitals in France: *war* surgery is *ward* surgery.

In peace surgery the chief work of the operator and his assistants consists of the preliminary examination of the patient and the skilled surgical technic and anesthesia during operation. There are few open and infected wounds to treat, and as a rule the senior surgeon pays little attention to them, and the junior surgeons have much to learn.

In industries there has been a tremendous improvement in the surgical departments, and with this the same improvement in the healing of the wounds. Industrial surgeons of experience, such as Sherman of Pittsburgh and Noland of Birmingham, express the opinion that the Carrel method has led to improvements in their results.

I cannot agree with Dr. Bevan that *one morning* spent at the Carrel Institute gives sufficient opportunity to judge the value of the method, and I see no impropriety for Dr. Hartwell to consult during the operation with a French army officer as to some of the details in starting the Carrel method.

Nor can I agree with Dr. Bevan in regard to his conclusion on Carrel's book. Carrel had an excellent team, and attacked the problem in a most scientific and broad way. He employed controls.

When Carrel started his investigation, the majority of military surgeons were by no means satisfied with any of their methods, or with their results. The excision of the wound in the stage of contamination, or the thorough cleansing of the wound in the stage of infection and its wide opening were methods already employed when Carrel started. His contributions to the open wound treatment are: a most effective instillation tube; the adjustment of the tube or tubes so that every portion of the surface of the wound in every nook and corner is continuously bathed in an antiseptic solution that is most potent in its effect on the bacteria and least injurious to the granulation tissue and to the power of the cells and fluid against the bacteria themselves. Carrel, apparently, was the first to prove with bacteriologic control that an open wound could be practically sterilized and then closed.

In the huge wounds of this war, there seems no question that the sooner they are closed the better. The opponents of the Carrel method do not question the scientific precision of his technic, or his results; they claim, however, that his technic can be followed out successfully only in a stationary hospital with a large personnel, and that it is expensive in time and material. In addition, they claim that the technic is difficult; that his solution requires an expert to prepare it, and that it must be guarded, or its effective strength may be lost.

Carrel's method and results have been the chief stimulants to investigation by others for a method that will be equally good, but simpler and less expensive. The investigators who are advocating dichloramin-T take this ground.

In reading the contributions and studying the motion pictures presented by Captain Furnes and Lieutenant Lee, one is impressed by the fact that their investigation has led to a marvelous improvement in the technic of treating the ordinary accidental or industrial wound; and they have accomplished this with economy of time and material. But up to the present time I am unable to agree with them that the methods with dichloramin-T accomplish the same result in the huge open wounds which often contain necrotic tissue, and it is chiefly for this group of wounds that Carrel developed his technic.

I am not claiming that Carrel's method will be the ultimate solution of the problem, but I do claim that up to the present time it is the one great contribution to wound treatment, and that the ultimate treatment will be due to, and based on, Carrel's clinical and scientific research; and every surgeon who expects to treat wounds in this war should have special training in all the laboratory and clinical details of the Carrel method. Joseph Colt Bloodgood, M.D., Baltimore.

A Reply by Dr. A. T. McCormack

To the Editor:—In The Journal, Nov. 17, 1917, appears a letter by Dr. Arthur Dean Bevan in regard to the Carrel-Dakin treatment. This letter is based on such a complete misconception of Dr. Carrel's work and motives, and is so untimely and ill considered that one who does not know and admire Dr. Bevan, as I do, might wonder whence the source of his inspiration in attempting, in an academic discussion, to throw confusion into the Medical Department of our Army in regard to such an important scientific question. I respectfully submit that no man, however distinguished himself, is the final judge on scientific matters, and that especially if he be in a position of great responsibility, conferred upon him by the profession, he has no right to give publicity to a personal letter which lends the weight of his authority to a destructive criticism without a semblance of investigation or knowledge of a conscientious scientific investigator and his associates, and a method of management of infected war wounds, which, in the hands of those skilled in its application, has demonstrated its value. His misconception of Dr. Carrel's technic and purposes is the only thing made plain in this letter.

In all the real scientific principles involved, wherein Dr. Bevan correctly interprets the findings of scientific clinical surgeons the world over, his conclusions had already been as well stated by Dr. Carrel in recording the results of his investigations.

Over and over again, Dr. Carrel emphasizes and reemphasizes the problems of surgical pathology, and exhibits a profound critical, scientific knowledge of them. Over and over again, he states that Dakin's solution and the Carrel technic are modifications in method, and in no way change the principles underlying modern surgery. Over and over again, he states that some other antiseptic applied by another modification of technic may eventually be found more practical than the one which bears his name; but he insists, and so will every one who really knows his work and who is interested in a proper conclusion of this matter, that whatever the technic, whatever the antiseptic proposed, its value shall be judged by exact, modern, scientific methods and not by the *ipse dixit* of some scientific clinical surgeon or surgeons, simply because he or they are willing, without a claim to personal knowledge or a pretense of scientific investigation, in the emergency of a great war where so much is at stake, to base the condemnation of a scientific method on a mere analysis of a little *précis* or manual which plainly states that its chief purpose is to refresh the memory of those who have participated in the course of study of the treatment under one who has had it demonstrated to him until he has mastered it.

If one were so unjust to Dr. Bevan as to characterize this publication of a personal letter based, as he says, on letters from Joe this, and Fred that, and one operation done by Josh somebody else, and the hurried and superficial reading of a book whose whole purpose and character he so evidently misconceives, he would not do justice to so charming a man.

The Carrel-Dakin treatment is not advanced as a miracle or cure-all, nor is it expected that it will take the place of all other methods in the treatment of wounds and injuries. It is above all not expected that it shall be utilized by that class of scientific clinical surgeons who base their opinions on the internal evidence of books, rather than on knowledge of and experience in a method that can be seen with the eyes of the trained observer and correctly verified with the microscope and in the chemical laboratory. Boric acid, aluminum acetate, Dakin's solution, Labarraque's solution, brilliant green, iodin, phenol, chloramin-T and dichloramin-T, hydrogen peroxid, normal salt solution, sterile water, mercuric chlorid and many other antiseptics, of varying dilutions and value, have been so thoroughly tried out and the results of their applications so fully charted, by exactly the same painstaking methods, and by a scientific staff and allied investigators, that the surprise of his life awaits any scientific clinical surgeon who bases his confidence in the future of surgical development on the history of the science, rather than on the scientific practice of the art.

All surgeons agree that the vast majority of war wounds are infected. This fact has been proved in every war hospital in Europe, and, before that, was known to every man who has rightly read the history of war. After the mechanical cleansing, which is entirely surgical, based on the well known principles of surgical pathology and which Dr. Carrel would evaluate not at 90 per cent., but as the *sine qua non* of success with any method of antiseptic treatment of wounds, he insists that the next step is sterilization of the wound. This does not mean *apparent* sterilization, but *surgical* sterilization under bacteriologic control. Each day or two days, smears are made from various parts of the wound, and the bacteria present are stained and counted. If streptococci, staphylococci and bacilli are absent, one must find not more than one other microbe to five or ten fields before the wound is surgically sterile. If this degree of sterility is secured before the twelfth day, there is rarely cicatricial tissue about its edges, the skin is not adherent, and the wound may be closed with adhesive plaster or sutures, as is most desirable. After the twelfth day, it is necessary to dissect away the cicatrices about the edge of the wound, and it is the better practice only to insert the sutures, continuing the application of the antiseptic for a few days, to be sure that sterility is maintained before they are tied. Surgical pathology would, of course, dictate that in the presence of edema there would be no wound closure.

Dr. Carrel states that the conditions requisite for action of any antiseptic are contact, proper concentration of solution and a sufficient time. He states it so frequently that the most superficial observer should know that he believes he has proved that the wound must be so prepared by the practical application of the principles of modern scientific surgical pathology that the antiseptic being tested must come in contact with the tissue itself, and that all necrotic tissues and foreign bodies must have been removed and hemostasis be perfect.

In the Carrel technic, the Dakin solution is brought into contact with all parts of the wound through the insertion of rubber tubes of certain dimensions, having perforations of exact sizes at certain intervals, so that the desired concentration of solution will reach every part of the wound every two hours. This contact of the antiseptic in this exact concentration of solution shall be continued for the time necessary to bring about asepsis. Dr. Carrel states, always, that this is no new treatment. It is well known that Chattanay discovered the action of chloramins long ago, but the *systematization is, however, new,* and it is perfectly evident to the most casual reader that it is as new to many of our most distinguished scientific clinical surgeons as to the thousands of wounded soldiers who have been restored to the front by its application, where other methods left them languishing in the hospitals or resulted in loss of limbs or life.

But Dr. Carrel has gone much farther in his search for a definite means of expressing the value of an antiseptic. He has found from extensive study of the actual wounds themselves, working with others to whom he gives most of the credit, that there are definite laws of cicatrization. A surgically sterile wound, carefully measured, and its area determined by a planimeter, at four day intervals, will cicatrize at a rate which is capable of expression in a mathematical curve, and may be demonstrated by a mathematical formula. Practically, each surgically sterile wound is measured, its area plotted, and this is repeated and recorded every four days. With these and certain other factors known, the normal curve of cicatrization of that particular wound is calculated. Afterward, repeated measurements at four day intervals show how much the treatment applied by the surgeon *delays* cicatrization. Dr. Carrel states definitely and repeatedly that *no known treatment hastens cicatrization,* but that surgical sterilty is an essential prerequisite to the normal rate of cicatrization.

This method of mathematical control of cicatrization is applied not only to wounds in general but to each particular wound, so that the scientific surgeon, properly advised by a practical bacteriologist, is able to know when normal cicatrization has been delayed either by the *laissez faire* policy of some scientific clinical surgeon leaving behind necrotic tissues to be cared for or foreign bodies to become encapsulated or by any other condition demanding surgical interference.

I am not attempting to give any further details than are necessary to show that the Carrel-Dakin method of treatment of war wounds is based on scientific data, against which the fiat of any one cannot and should not prevail. Repeated contact with Dr. Carrel leads us to recognize in him a degree of scientific precision and personal modesty that would prevent his replying in kind to such a letter.

Exactly such a misconstruction of Lister's work as is attempted in the Bevan letter has ever since kept many surgeons from getting the benefit from antiseptics that Lister did, while other practical men, refusing to be misled, have continued to secure Lister's results by the real application of Lister's methods, disregarding his necessarily faulty lines of reasoning in regard to them.

Dr. Bevan, by this attack without study or practical knowledge of his subject, is but repeating history. Semmelweis, Jenner, McDowell, Crawford Long—every man who has advanced the practical art of medicine, has had some one of the priests-of-the-vested right-in-knowledge to condemn him and his methods and results in unmeasured terms, and our profession has rarely recognized during their lifetime its best promoters except by the contumely and condemnation of the self-righteous.

It is important for the profession to understand that its final verdict on Dr. Carrel's definite method of the treatment of infected war wounds by the use of Dakin's solution is likely to be more influenced by erroneous comment from three sources than by the merits or demerits of the method itself. These are likely to come, first, from those who condemn academically without either investigation or knowledge; secondly, from those who accept the suggested treatment because it is novel and new without knowledge or investigation, and who, without understanding the reason, change or modify the technic so that it becomes wholly inadequate; and, thirdly, from those who honestly think they have investigated the Carrel-Dakin technic when really they have studied the work of some one of the second class. It is a serious question whether such a method, requiring what seems to one first seeing it a somewhat complicated technic is not more in danger of being misjudged from the statements of its ill advised and frequently overenthusiastic advocates, than of its ill informed and reactionary opponents.

Arthur T. McCormack, M.D., Bowling Green, Ky.

FUND FOR BELGIAN AND FRENCH PHYSICIANS

To the Editor:—In order to further the subscriptions to the fund being collected by Dr. W. W. Keen of Philadelphia for transmission to our Belgian and French colleagues to help them in reestablishing themselves in their homes and offices. I should be very glad if you could find space for the enclosed letter from Dr. Triboulet of Paris. Dr. Triboulet is a distinguished physician of the Hôpital Trousseau, and was in this country at the time of the International Congress on Tuberculosis in 1908.

Henry Barton Jacobs, M.D., Baltimore.

Dear Dr. Barton Jacobs:—After three years of the most frightful cataclysm, France is always up. She has saved herself and the civilized world; at which cost you may think of it by the narrations you may read; they are nothing compared with the reality. Some of the oldest and richest provinces (in soil, industry, and art) are now a desert. Today, tomorrow and days after tomorrow we must use all our energy and money in building again and in helping those who are in awful distress. Among the latter are the medical faculties, and I hesitate no more to send you and the U. S. confrères the most earnest appeal. If indiscretion is not too great, will you allow me to ask you to be an intermediary for this international medical problem: to give our spoiled confrères the necessary means to come back and live in their devastated homes. The French medical associations will collect nearly a million francs by corporations, private funds.. In our northern invaded departments (Oise, Somme, Pas de Calais, Aisne, Nord, Marne, Ardennes, Meuse et Meurthe et Moselle), there are 2,000 doctors. From these 2,000 confrères, *1,000,* at least, will want material help to begin again their professional life, and we think five thousand francs—5,000 Fs.—the necessary sum of money for each one. The million we possess is every day lessened by the necessity of immediate help to the expelled medical families, when repatriated day after day, or week after week.

I hesitated a long while before writing this: U. S. A. did do, and will do so much for France, that one is quite ashamed to ask again. But proudness is unreasonable in such questions, and I make myself very humble for the sake of the confraternal misfortunes. A sort of incitement came a few days ago when the Uruguay confrères sent us spontaneously 35,000 francs in a cheque.

My family gave three "poilus" to dear France; one, aviator, one artillery officer; both wounded and cured, and started again; the third in Engineers Corps, a young 18½ fellow.

Magnin's son is a brave little one; he is in the Saloniki Army in the medical staff. French, and I am sure U. S. youth is full with ardor and confidence. "On les aura" is the common expression. Don't judge our people in books or in newspapers; one must see him at work; that is *splendid.* In a near future, you will come and see that, and you will find here an old man very, very happy to see you at the well deserved peace-hour. Long live the sister republics!

Henri Triboulet,
25, Avenue d'Antin, Paris.

Connecticut July Examination

Dr. Edwin C. M. Hall, secretary of the Connecticut Homeopathic Medical Examining Board, reports the written examination held at New Haven, July 10, 1917. The examination covered 7 subjects and included 70 questions. An average of 75 per cent. was required to pass. Four candidates were examined, all of whom passed. Two candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
New York Homeopathic Medical College and Flower Hospital (1916) 87.2; (1917) 76.5, 80.1, 83.4.			

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Boston University		(1912)	Mass.
New York Homeopathic Medical College and Hospital		(1904)	New York

West Virginia July Examination

Dr. S. L. Jepson, health commissioner of the West Virginia Public Health Council, reports the oral, practical and written examination held at Charleston, July 10, 1917. The examination covered 10 subjects and included 100 questions. An average of 80 per cent. was required to pass. Of the 38 candidates examined, 31, including 3 osteopaths, passed, and 7 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Georgetown University	(1910)	80.2
Chicago College of Medicine and Surgery	(1917)	89.3
Loyola University (1915) 85.8;	(1916)	86.6
Kentucky School of Medicine	(1898)	84.8
University of Louisville (1913) 85.8;	(1917)	88.8
Maryland Medical College	(1904)	89.2
University of Maryland (1917) 80.3, 81.5, 81.7, 83, 84.9, 89.4.

Book Notices

The Elements of the Science of Nutrition. By Graham Lusk, Ph.D., Sc.D., F.R.S., Professor of Physiology at Cornell University Medical College, New York City. Third Edition. Cloth. Price, $4.50 net. Pp. 640, with 28 illustrations. Philadelphia: W. B. Saunders Company, 1917.

Lusk was a pupil of Voit and the Munich school of metabolism. He returned to America with the spirit and principles of thought which made that school great, continuing here to perform productive experimental work. He has trained a corps of younger men along similar lines, and by this book has greatly helped the spread throughout the country of a sound knowledge of the elements of the science of nutrition. The issue of the present war will depend in a large degree on the ability of nations to solve problems of alimentation, to apply and develop further such facts and principles as form the subject matter of this book. It is fortunate that we have a body of men trained in these lines to apply and teach the facts of metabolism and discover new ones as needs arise. The fact that we have them has been due in no small measure to the influence of this author and this book. The value of the latest edition is increased especially by its authoritative presentation of much newer data won by E. F. Du Bois, J. R. Murlin and other men more or less directly affiliated with the writer. At the present time, perhaps, interest will center in the chapter on a normal diet, the new chapter on food economics, with special reference to the war, the chapter touching the nutritive value of various materials used as foods, that on food requirements during the period of growth, and on the revised food tables. The sections dealing with the metabolism taken as a whole, particularly as revealed by the respiration calorimeter, show, as in previous editions, the hand of the master. They outshine in excellence those parts of the book that deal with the mechanisms of chemical reactions within the body.

In the preface the author states that he has no intention of again revising this book, because in another decade the development of scientific knowledge will probably permit the formulation of the subject from the standpoint of physical chemistry. It is to be hoped that progress may be sufficiently rapid to fulfil this interesting forecast. In the meantime the present volume must be regarded as a notable achievement which should be made available in every laboratory, diet kitchen and home in this country.

The Principles of Acidosis and Clinical Methods for Its Study. By Andrew Watson Sellards, Associate in Harvard Medical School, Department of Tropical Medicine. Cloth. Price, $1. Pp. 117, with 1 illustration. Cambridge: Harvard University Press, 1917.

Under normal conditions, the ingestion of 5 grams of sodium bicarbonate is followed promptly by a change in the reaction of the urine from acid to alkaline as tested by litmus. In the nephritis of Asiatic cholera and in certain other forms of nephritis not due to cholera, Sellards has noted an increase of the tolerance for bicarbonate, that is to say, massive doses of this salt may be required to make the urine alkaline to litmus. He interprets this phenomenon as due to nephritic acidosis rather than to nonexcretion of the base; and, departing from these experiments, Sellards advocates determining the tolerance of the body for sodium bicarbonate as the most delicate and practical clinical method of diagnosing acidosis. One may thus detect deficiencies of from 20 to 30 gm. in the bicarbonate reserve of the body. The author claims priority over Henderson and Palmer in the use of this method.

The book has an introductory chapter on the development of the modern conception of acidosis, and some elementary facts concerning acids and bases. A current view of the mechanism by which the reaction of the blood is kept constant and by which the body maintains its equilibrium of acids and bases is briefly stated. There is a definition of acidosis in agreement with L. J. Henderson, D. D. Van Slyke and others, and of the principles underlying its clinical diagnosis, together with the pros and cons of several methods of estimating acidosis. The writer strongly endorses an appropriate use of alkali in the treatment of certain acute types of nephritis, thus recalling the views of M. H. Fischer, although Sellards denounces the use of hypertonic sodium chlorid.

A bibliography contains references to seventy-one contributions on the subject of acidosis prior to 1917. The book serves the purpose of bringing together in convenient form what every physician should know about acidosis. It is marred slightly by its use of an obsolete chemical nomenclature, such as oxy in place of hydroxy butyric acid.

The Sense of Sight. By Frank Nicholas Spindler, Professor of Psychology and Education, State Normal School, Stevens Point, Wis. Cloth. Price, $1.25 net. Pp. 156, with 25 illustrations. New York: Moffat, Yard & Co., 1917.

In endeavoring to convey what the sense of sight means to us, the author has given a sketchy description of the anatomy, physiology and physics of the eye; of the predominant influence of vision in the acquisition of knowledge of external things, and of its part in the development of mentality and the emotions. He says, and has attempted to show by experiments made according to a method which he lays down, that about 60 per cent. of persons are visual minded as distinguished from auditory or motor minded; that is, they acquire knowledge by seeing things or reading about them rather than by hearing or doing them. This is not wholly a desirable state of affairs, but is fostered by modern modes and habits of life and the constant flood of newspapers, magazines and books, which every one reads for himself, thus permitting to fall into disuse the arts of listening, of conversation, of writing, and, be it said, of thinking. He makes a plea for the extension of coordinate education of eye and ear and hand, as taught by Pestalozzi, Froebel and Montessori. The visual type of mind is quicker to learn, but is apt to be more superficial. Few noted scientists or scholars are of the visual type; but artists, architects and designers are apt to be. It is highly desirable to cultivate the acquisition of knowledge through the sense of sight and to take proper care of its organ, but it is important also to develop all the other senses, to give a rounded, complete intellectual background for what the eye visualizes.

Medicolegal

Privileged Knowledge and Roentgenograms—Right to Select Physicians

(Stapleton vs. Chicago B. & Q. R. Co. (Neb.), 162 N. W. R. 644)

The Supreme Court of Nebraska holds, in this personal injury case, that when a party submits to an examination, or inspection, by a physician, for the purpose of learning the state of his health or the physical condition of any part of his anatomy, the knowledge thus acquired by the physician is privileged, and, under Section 7898 of the Revised Statutes of Nebraska of 1913, the physician is not permitted to testify to the condition he found, over objection based on the statute. And when a plaintiff has permitted a physician to make a roentgenogram of his injured foot for the purpose of ascertaining the extent and character of his injuries, the roentgenogram so made is not admissible in evidence over objection of the plaintiff based on the statute.

The court says that the statute cannot be given a strained construction, but must be taken in its plain and ordinary sense. When it says that a physician shall not be allowed to give testimony or to disclose confidential communications properly intrusted to him in his professional capacity, and necessary and proper to enable him to discharge the functions of his office, it means to exclude the disclosure of any information that comes to such physician by reason of the professional capacity in which he acts. It does not matter whether the patient seeks a prescription for a disordered stomach or a roentgenogram of an injured foot. Nor does the statute make any distinction between a regularly retained physician of a railroad company, who is paid for his services by the railroad company, and a physician paid by the patient. And the same rule which would exclude the oral testimony of the physician would exclude the roentgenogram of the plaintiff's foot. Its introduction in evidence would be a disclosure of a confidential communication.

The defendant complained because on cross-examination it was not permitted to inquire whether the plaintiff had submitted himself for examination to specialists for the purpose of qualifying them as witnesses, and that he did not intend to produce these witnesses on the trial. This line of examination was not pertinent to anything developed in the examination in chief of the witness. He had the right to select his own physicians and his own witnesses. If counsel for the defendant disbelieved the testimony of the physician who testified as to the character and extent of the plaintiff's injuries, he might have procured the testimony of men eminent as physicians and surgeons by application to the court for the appointment of a commission to make an examination of the person of the plaintiff.

Authority to Treat Employee Beyond Thirty-Day Period

(In re Carpenter's Estate (Mich.), 162 N. W. R. 963)

The Appellate Court of Indiana, Division No. 1, says that the industrial board of the state certified to it the question of law as to whether a physician who treated an injured employee eighty-seven days from the date of the injury was entitled to have his claim for $171 for the last fifty-seven days' treatment approved as against the employer, under substantially the following statement of facts: The employee by an accident arising out of and in the course of his employment sustained severe third degree burns over his face, head, chest and hands. His employer had actual personal knowledge of the injury at the time it occurred, and employed the physician to treat the injuries, saying to him: "Take this man to the hospital, give him close attention, and do the best you can for him." The employer did not, at that time, or at any other time, expressly say to the physician that he should discontinue his treatment at the expiration of the first thirty days from the date of the injury, or that he should continue his treatment after the expiration of thirty days, but on frequent occasions, both before and after the expiration of the thirty days, inquired of the physician as to the condition of the employee and what progress he was making toward recovery. At the expiration of thirty days, the condition of the employee was such as to make continued treatment absolutely necessary. As a result of the treatment, the employee recovered with practically no scar tissue and without serious disfigurement. The employer admitted that the physician's bill of $171 for the treatment for the last fifty-seven days was reasonable and a proper charge under Section 26 of the Indiana workmen's compensation act, but he denied liability therefor.

The court thinks that the language used by the employer immediately following the injury, in directing the physician to treat the injured employee, standing alone, would warrant the inference that the treatment should continue so long as necessary to effect a cure or give the injured person every possible chance to be cured. Such statements of the employer, considered in connection with the character of the injury, the employer's knowledge thereof, and of the continued treatment by the physician beyond the thirty-day period, and his apparent solicitude about the treatment and the patient, were at least sufficient to warrant the proper tribunal in inferring the fact that the employer duly authorized the physician to continue the treatment for the full period for which he asked an allowance.

However, unless this court can say that the foregoing is the only inference that may reasonably be drawn from the facts stated, it is not warranted in going further than to decide as a question of law that such inference may or may not reasonably be drawn from the facts as stated. The determination of questions of fact by the board is conclusive, and in view of this rule the court deems it proper to leave the finding of the ultimate fact to the board, with the further statement that if, in the judgment of the board, the services of the physician beyond the first thirty-day period were authorized by the employer, the question of law propounded by the board should be and is answered in the affirmative; otherwise, in the negative.

SOUTHERN MEDICAL ASSOCIATION

Eleventh Annual Meeting, held at Memphis, Tenn., Nov. 12-15, 1917

The President, Dr. Duncan Eve, Nashville, in the Chair

Tumors of the Urinary Bladder

Drs. Edward S. Judd and **S. W. Harrington**, Rochester, Minn.: From a therapeutic standpoint, bladder tumors may be classified as those satisfactorily treated by endovesical methods and those requiring open operations. The benign papilloma will usually respond to fulguration. Multiple papillomas, or individuals not tolerant to this kind of treatment, are better treated by open operation. All our bladder tumor cases are examined cystoscopically at definite intervals following operation to detect a recurrence. In the past few years we have found fourteen recurrences that were amenable to fulguration. In case the benign tumor does not respond readily to fulguration, it should be removed by an operation. They may be malignant. All definitely malignant papillomas, either of the papillary type of carcinoma or of the type infiltrating the bladder wall, are best treated by open operation at once. All large benign tumors, such as myomas, fibromas and angiomas, should be removed by suprapubic operation.

The operative procedure for tumor of the bladder consists of excision of the tumor and resection of the portion of bladder wall from which the tumor arises. A simple excision of the tumor is permissible only in the case of a papillary tumor on a pedicle. Even with this form of tumor, it is better to excise a portion of the adjoining bladder tissue. This means invasion of the prevesical space; but with modern technic, it adds little, if anything, to the operative risk. If the resection is not extensive, the remaining opening can be closed, and drainage established through the bladder. If a large segment of bladder is removed, it is better to drain the space for several days. The drain can be brought out through the bladder or along the side of the bladder. If the prevesical tissues are exposed, drainage is essential.

Hypertrophic Pyloric Stenosis in Infancy

Dr. William D. Haggard, Nashville, Tenn.: Pyloric stenosis presents a picture so characteristic and clear cut that diagnosis should not fail. The symptoms may appear within a few days of birth, or be delayed until the second and rarely the third month. Vomiting is the first symptom usually noted. A previously healthy, normal, usually robust, breast fed boy begins to vomit abruptly in the third or fourth week without apparent cause. To the persistent, explosive, forcible vomiting are added symptoms of faulty nutrition, constipation, oliguria and steady loss of weight. Visible gastric peristalsis is a constant symptom. The wave passes from left to right, and may be elicited after food has been taken. Palpation a little to the right and above the umbilicus often reveals a tumor about the size and shape of a small green olive. The tumor is most distinct in the more severe cases, in patients with thin, retracted abdominal walls. It is variable in its position, and may be out of reach under the liver. If every patient with hypertrophic pyloric stenosis was operated on as soon as the diagnosis is made, the mortality might be reduced 10 or 15 per cent. Failure to seek prompt surgical relief is too often fatal. Even though the baby may apparently be holding its own under medical treatment, it may suddenly, and without apparent cause, become progressively worse and die in a short time.

Treatment of Acute Diffuse Peritonitis

Dr. H. A. Gamble, Memphis, Tenn.: The abdomen is opened under general anesthesia, the primary lesion is removed or repaired, split rubber drainage tubes with gauze wicks are introduced into Morrison's pouch, the pelvis, and wherever else indicated, and the work is completed as expeditiously as possible. Free drainage is maintained, elimination promoted, the strength of the patient sustained, and complications are guarded against. The patient is put in the sitting posture, and 500 c.c. of physiologic sodium chlorid solution are injected subcutaneously. This is repeated from every four to six hours. Plain warm water is started also at once by Murphy's method of proctoclysis. Dressings are changed frequently, from every one to two hours, for the first twenty-four hours. The most important complications to be guarded against, in the order of their frequency, are acute dilatation of the stomach, secondary abscesses, intestinal obstruction, and phlebitis.

Latent Manifestations of Syphilis in and About Joints

Dr. Edward S. Hatch, New Orleans: Joint syphilis is much more common than is generally supposed. In the roentgen findings and in the luetin reaction we have nearly positive diagnostic aids. A roentgenogram, a Wassermann test and a luetin reaction should be made in all suspected cases, and then, if there is doubt, the therapeutic test should be applied.

Use of Radium in Nonmalignant Uterine Hemorrhage

Drs. C. Jeff Miller and **E. L. King**, New Orleans: The nonmalignant conditions of the uterus causing menorrhagia or metrorrhagia may be thus grouped: 1. Cases in which there is little or no demonstrable pathologic change in the uterine wall, no history of infection, and in which the uterus is apparently normal in size and position, with normal adnexa. In such cases, the bleeding is, in all probability, due to some disturbance of the internal secretions, especially of the thyroid or of the ovary. This condition is often encountered in young girls about puberty. 2. The menopause. 3. Chronic metritis. 4. Hypertrophy or hyperplasia of the endometrium, especially when so marked as to be adenomatous or polypoid in character. 5. Fibroids, adenomas or adenomyomas of the uterus. 6. Chronic endometritis, especially after incomplete abortion. 7. Passive congestion of the uterus, as in retroflexion or prolapse. In the first three groups, radium may be used to the exclusion of surgery; in the fourth and fifth, some cases are suitable for radium and others require operation; while in the sixth and seventh groups, operation is indicated.

We have treated ten cases classified under the first two groups. In all of them the bleeding had persisted for years and had resisted every form of treatment. Nine of the patients were given intra-uterine radium treatments, the average dose being about 1,000 milligram-hours. In only one patient did the treatment fail to relieve the condition. Only one patient suffered from severe menopausal symptoms, although in several of them the symptoms were present in a mild degree.

Eighteen cases fall in the third and fourth groups. The patients ranged in age from 30 to 55, and most of them had suffered from bleeding for several years—as a rule, menorrhagia first, and later metrorrhagia as well. In every case, radium treatment was followed by amenorrhea; in two patients there was a recurrence of the bleeding about one year later, the flow being approximately normal. The others are still relieved. Six patients suffered from marked menopausal symptoms; five others were similarly affected, but the symptoms were mild and transient. The patients suffering most from the artificial menopause were nearly all between 40 and 51; this coincides with our experience after hysterectomy. In three women, aged 35, 45 and 51, the condition was relieved by corpus luteum extract. Eight patients suffered from leukorrhea for two or three months after the treatment. In those cases in which subsequent pelvic examinations were made, marked reduction in the size of the uterus was found, and the tenderness, as a rule, disappeared. The dosage in these cases was from 500 to 1,000 milligram-hours.

Rôle of Syphilis in Surgery

Dr. George Gellhorn, St. Louis: I have seen extensive suppurations of the abdominal incision resist all possible treatments for weeks, but turn into clean and vigorously granulating wounds when antisyphilitic treatment was instituted. I have in my care a woman with tertiary syphilis in whom several surgeons have unsuccessfully attempted to repair a third degree laceration of the perineum. I subjected this patient to energetic antisyphilitic treatment with the view of softening the cicatricial tissues about the vulva, and of forestalling disturbances of wound healing. In the course of this treatment, which included several injections of salvarsan, a laparotomy for pus tubes became necessary, and the patient went through this operation without the slightest complication.

KENTUCKY STATE MEDICAL ASSOCIATION

Sixty-Seventh Annual Meeting, held at Louisville, Nov. 6-9, 1917

The President, Dr. P. H. Stewart, in the Chair

A Plea for Better Diagnosis.

Dr. R. M. Rankin, Covington: Standing in the foreground among the means for accomplishing the purpose of this plea is the grouping of physicians in institutions and in office buildings in cities and towns. Success presupposes a leader, with competent workers properly equipped. The superior diagnostician working alone is superior, perhaps in greatest measure, by reason of his doing as well as he may the work performed by specialists comprising the group. Specialists in particular fields probably succeed in making diagnoses by reason of special knowledge of the symptomatology pertaining to that field and by special effort to elicit the symptomatology. Better equipment oftener used would add materially to the efficiency of all of us.

DISCUSSION

Dr. W. A. Jenkins, Louisville: It is a good sign to see the universal interest that is being manifested in the making of proper diagnoses. Even the laity, after hearing addresses before civic audiences, health boards, and other bodies of a similar character, are now recognizing the importance, the necessity and the desirability of accurate diagnoses. It is only by education and careful training in all modern methods that accurate diagnoses can be made.

Dr. Bernard Asman, Louisville: It is not unusual to see a patient suffering from advanced cancer who has been treated and is still being treated for some simple ailment presumably the cause of the trouble.

The Precancerous State and the Increase of Cancer

Dr. A. H. Barkley, Lexington: When patients present themselves because of a condition that is suspicious of beginning cancer, or one that is likely to become so ultimately, they should be examined thoroughly and conscientiously, and the benefit of any doubt should be given the patient. By means of lectures the public should be taught the great benefit to be derived from periodic examinations from head to foot. In cancer, as in other diseases, attention to diet, exercise and proper hygienic surroundings is of distinct value.

Precancerous Lesions

Dr. Irvin Abell, Louisville: Notwithstanding the possibility of underlying general factors, cancer may, for all practical purposes, be regarded as local in its beginning. Prominent among the predisposing factors for which one should be on guard are: general lowered nutrition; chronic irritation and inflammation; repeated acute trauma; cicatricial tissue, such as lupus and other scars, and burns, benign tumors, warts, moles, nevi, etc.; also the fact that changes occurring in the character of such tumors and tissues, as well as the occurrence of any abnormal discharge from any part of the body, especially if blood stained, are to be regarded as suspicious. Some occupations, notably working in pitch, tar, paraffin, anilin or soot, and with roentgen rays, if not safeguarded, are conducive to the production of cancer, presumably on account of the chronic irritation or inflammation caused. The finding of any abnormal condition about the body should be taken as an indication for competent professional and not personal attention.

DISCUSSION

Dr. J. Garland Sherrill, Louisville: It should be the duty of the physician to educate his patient to keep away from sources of local irritation. Whatever the relationship between an injury to the tissues and the development of cancer, it is our duty to urge these patients to take care of this irritation or injury, in order that they may not develop malignant disease later.

Diagnosis of Gallbladder Disease

Dr. A. W. Nickell, Louisville: We are principally interested in two types of this disease, cholecystitis and cholelithiasis. Gallbladder disease is second in importance only to appendical inflammations. In the operations for gallbladder disease, there was sufficient pathologic justification for removal of the appendix in 69 per cent. of MacCarty's cases, and in 68.2 per cent. of Smithies' cases. While the gallbladder is the seat of stones in the majority of cases, inflammation of a noncalculous origin may occur. In 1,000 cases reviewed by Smithies, there were 434 cases of acute and chronic cholecystitis in which neither gallstones, "sand" nor malignancy was demonstrable. Out of this number of 434 acute and chronic cases, 228 were of the acute catarrhal type. Stones complicated in 51 per cent., and "sand" in 8 per cent. Cholecystitis will occur in old persons with the former state of health fairly good after indiscretion in diet. Symptoms similar to gallstones may be caused by pancreatic calculi; but these cases are so rare that they scarcely enter into the diagnosis. Floating kidney may simulate gallstones. The most difficult cases to diagnose are those in which the gallbladder, stomach and bowel are bound together by adhesions by either numerous attacks of gallbladder inflammation or ulcer. There is, then, a commingling of gastric and hepatic symptoms with hyperchlorhydria. We may have to differentiate the crises of locomotor ataxia. A good rule in all cases of supposed gallstone colic is to test the knee jerk, station and pupils. The Wassermann test is of value here.

Skin Lesions Due to Focal Infection and Septicemia

Dr. M. L. Ravitch, Louisville: Most cases fall under three heads. First is the type in which the lesion is confined so closely to the tissues near the focus of infection as to suggest very strongly infection along lymphatic channels or by contiguity of adjacent structures. The lesions are usually considerably elevated, more or less irregular in outline, fairly well defined, and nearly always distinctly red or pink, instead of purple or bluish as seen in other types. The second class includes lesions caused by hematogenous infection from one or more foci of infection. Instead of being confined to the locality of the focus, the lesions may appear in quite distant tissues; there may be recurrent crops well generalized, or fairly persistent patches in one or two areas. There seems a certain amount of predilection for the head, neck and upper chest when the focus is above the trunk; the abdomen is more apt to show the lesions in appendical or renal abscess. The third class is the most dangerous. Here we are dealing with a septicemia, sometimes quite mild, sometimes very virulent. In addition to the skin lesions, there is nearly always discoverable an arthritis, endocarditis, septic nephritis, or endometritis. Frequently the onset of the septicemia manifests itself by the appearance of scattered hemorrhagic elevated nodules in the skin, sometimes confined to one locality of the body, but more usually appearing on the face, abdomen, thighs and ankles, if not all over the body. Within a week the infection of the skin has reached its height, and it usually begins to ameliorate somewhat after that, although fresh lesions may appear from time to time. The importance of recognizing these lesions cannot be overestimated. They are not only frequently the first symptoms of a virulent endocarditis, but often they lead to the detection and removal of a hitherto unsuspected, but very dangerous, focus of infection, in mouth, throat, ear, sinus or elsewhere. It should be the routine with physicians, whenever a case of erythematous lesions or purpuric patches comes under observation, to make a thorough examination for such infectious foci.

11 Meningitis Sympathica; Report of Cases. I. Strauss, New York.—p. 748.

1. **Wassermann and Spinal Fluid Tests.**—This paper comprises the study of 203 cases: 43 paresis, 34 tabes, 27 cerebrospinal syphilis, 4 congenital syphilis, 11 meningitis, 3 tetanus and 81 other nonsyphilitic organic and functional conditions. The characteristic paretic curve of the colloidal gold reaction was found in 42 cases out of 43 spinal fluids examined. Four cases gave a negative Wassermann in the blood; all showed a marked positive globulin test; all but 5 had a lymphocytosis of over ten cells per cubic millimeter. Of the three atypical reactions, 1 occurred in a very early case, 1 was probably due to an old and infected spinal fluid, and 1 was made after vigorous intraspinal therapy.

In the miscellaneous group (76 cases) all findings were practically normal. The Wassermann in the spinal fluid in all cases was negative. One blood gave a positive Wassermann, the cell count was normal except in 2 cases of meningismus, in 1 brain tumor and in 1 spinal cord tumor; the globulin test was negative in all but 1. The colloidal gold test showed nothing definite except occasionally a slight decolorization in the lower dilutions. In 3 cases of multiple sclerosis all findings were negative, but in 1 case the colloidal gold test showed a typical paretic curve with a negative Wassermann test.

The effects of antisyphilitic treatment on these tests have been variable. In the main the syphilitic cases have been treated with salvarsan, intravenously and intraspinally (Swift and Ellis method), combined with mercury. In all cases there has been a gradual reduction of the cell count to normal. In the majority of cases the globulin test has become normal while in some it remained slightly positive. In 21 cases of paresis, treated thoroughly, all but 2 gave a negative blood Wassermann. However, in the spinal fluid it persisted positive in every case. Out of 22 cases of tabes treated, 16, or 73 per cent., gave a negative Wassermann both in the blood and spinal fluid. In only five instances of all antisyphilitic cases treated did the author notice any change in the colloidal gold curve, and in only 1 case did the curve become normal. Hammes concludes that no spinal fluid test (except the presence of bacteria) is specific. Every test is simply that much cooperative evidence and should be combined with the history of the case and the clinical findings.

2. **Causation of Edema in Chronic Nephritis.**—The problem in the treatment of edema in chronic parenchymatous nephritis is to relieve the condition and prevent its recurrence. The mere removal of effusion fluid by paracentesis and puncture, if feasible, may relieve it partly, but does not, as a rule, prevent a reaccumulation. The indications are: (1) to increase the protein content of the blood and thus help it regain its normal osmotic power, and (2) to remove or cause the reabsorption by the tissues of the excessive lipoids. The restoration of the protein content may be accomplished by two methods: (1) Massive infusion or transfusion of healthy blood accompanied by the removal of equal quantities of blood from the patient. The latter procedure is necessary to accommodate the introduction of additional blood so as not to embarrass the circulation. It also serves to remove some of the excessive lipoids. (2) Most important is the proper administration of a high protein and fat poor diet. The employment of transfusion is undoubtedly helpful and affords a good start in the treatment, but is not always feasible for obvious reasons. Chief reliance must therefore be placed on adequate dietetic measures. These consist in the administration of large quantities of properly selected proteins with a minimum of carbohydrates and the exclusion of fats. The fluid allowed is restricted to the quantity present in the food, plus that which is necessary for the comfort of the individual patient, amounting usually to from 1,200 to 1,500 c.c. The amount of salt allowed is the quantity sufficient to make the food palatable.

8. **Colon Bacillus Pyelitis.**—Pyelitis in boys, although far more infrequent than in females, Graves says, is, from the standpoint of the individual case, possibly even more important. In the male subject the possibility of extension of infection through the lumen of the urethra may be excluded, and in the treatment of all cases the intestine is to be recognized and dealt with as the potential source of the disease. The possibility of the occurrence of unusual and severe systemic manifestations in well developed pyelitis should be better appreciated. The best routine treatment for pyelitis in children is the administration of sufficient alkali to render the urine alkaline and maintain this reaction. If hexamethylenamin is employed the formaldehyd excretion should be watched and the urine should be examined frequently, with a view of forestalling injurious effects on the kidney parenchyma. In all obstinate cases autogenous vaccine should receive a thorough trial.

9. **Cerebrospinal Fluid in Poliomyelitis.**—In the recent epidemic of poliomyelitis in Philadelphia the examination of cerebrospinal fluids made by the authors yielded the following results: The majority of the fluids were water clear or but faintly opalescent when viewed against a black background; but 1 or 2 per cent. of blood free fluids presented distinct turbidity. Xanthochromia and excessive fibrin formation were not found; about 10 per cent. of the fluids presented a small fibrin coagulum after standing several hours. Of the fluids, 77 per cent. from all stages showed an increase of total cells; in 80 per cent. of these the counts were not above 100 cells per cubic millimeter of fluid. An increase of the total cells was found in the preparalytic stage, and this increase was present in 95 per cent. of cases for at least three weeks after the onset of paralysis, after which the number of cells gradually decreased. In over 96 per cent. of fluids from cases after the onset of paralysis the small lymphocyte variety of cells predominated. Polymorphonuclear cells predominated in less than 1 per cent. of fluids, and in over 88 per cent. constituted less than 25 per cent. of the cells present. An increase of protein was found in from 32 to 42 per cent. of fluids, and different tests for protein yielded varying results.

During the acute stages of poliomyelitis the fluids from 40 to 50 per cent. of cases yielded a colloidal gold reaction of the syphilitic and meningitic zone types. All yielded negative Wassermann reactions. The potassium permanganate reduction test yielded positive reactions of indexes over 2.3, with the spinal fluids of 41 per cent. of cases examined from the second to twenty-first days after the onset of paralysis; a high reduction index indicates an increase of protein in the fluid, and may aid, therefore, in the diagnosis of acute poliomyelitis. Every fluid was found to contain sufficient glucose to reduce Fehling's solution in some degree; partial reduction of the amount of glucose was suspected with a number of fluids on the basis of a qualitative test. Increased permeability of the meninges was indicated by the presence of natural antisheep hemolysin in the fluids of 66 per cent. of cases in the acute stages and both the hemolysin and a hemolytic complement in 30 per cent. Both of these substances were absent in the fluids of control persons. Substances inhibiting saponin hemolysis were not found in the fluids of cases two to twenty-one days after the onset of paralysis.

18 Meningeal Syndrome and Other Sources of Error in Pyelitis. H. W. Dana, Boston.—p. 702.

12. **Operative Treatment of Ostearthritis of Hip Joint.**—Ozarki is of the opinion that in monarticular, nontuberculous cases it is always possible to relieve the disability of the leg by an arthrodesis, which can be repeated, if necessary. In polyarticular cases, if both hips are involved, the motion in one of the hips must be restored by some such operation as decapitation of the head of the femur. In cases of tuberculosis definite relief cannot be expected to the same degree as in ostearthritis, but the operation has produced no bad effect on the general or local condition, and has given marked benefit in the majority of the cases. Arthrodesis has appeared to be especially beneficial in cases which have arrived at a stage of disability where the patient is demanding a more serviceable leg. The leg will be stronger and less troublesome after the operation, and hence arthrodesis is the operation of choice in cases in which only one hip is involved. If an operation is required to restore motion in a joint, careful judgment must be used. In one case in which the ostearthritic affection was supposed to have subsided, it was thought that motion could be restored to the joint by a total excision of the head of the femur. If partial excision were the method chosen, it would be necessary to apply some protection against bony and capsular adhesions, and for this purpose the best material is furnished by free flaps of the deep fascia of the thigh, according to Dr. M. Sumita of Fukuoka, Japan, who in the year 1915 reported over eighty excellent results of various joints. This method will be successful if the refreshed bone surfaces are free from pathologic processes.

13. **Treatment of Myelocytic Leukemia by Radium.**—Thirty consecutive cases of myelocytic leukemia were treated at the Mayo Clinic by means of the surface application of radium element over the enlarged spleen. A certain degree of general improvement, together with reduction of the size of the spleen and of the leukocytic count, occurred in every instance, even in the most advanced and toxic cases. Marked temporary improvement occurred in twenty-six patients, and a remarkable improvement in thirteen. Hemorrhage ceased as a rule after one or two series of exposures. In two instances, hemorrhage occurred after radium exposures when it had not occurred previous to treatment. In these instances the hemorrhage seemed to be the result of overexposure; an anemia also developed; both the hemorrhage and the anemia were successfully combated by means of transfusion. In twenty-five patients there was definite improvement of the anemia concomitant with the improvement of the general condition. The reduction of the number of leukocytes was due chiefly to not only an absolute but also a striking relative fall in the myelocytes; there was a striking fall in the absolute count of polynuclears, while their relative percentage remained approximately the same. There was also a marked fall in the absolute count of small lymphocytes. Surface exposures of radium over the spleen of myelocytic leukemia usually effect a very rapid reduction of the size of the spleen, a fall of the leukocyte count, improvement in the general condition and together with transfusion, constitute at present the most effective temporary measure in the treatment of the disease.

30 Comparative Activity of Local Anesthetics. Paralysis of Motor Nerve Fibers. T. Sollmann, Cleveland.—p. 379.

26. **Artificial Iodization of Proteins.**—Employing the method described by Kurajeff, Rogoff and Marine have artificially iodized whole ox serum, ox serum globulin (obtained by half saturation of the serum with ammonium sulphate), ox serum albumin (obtained by saturating the filtrate of the globulin with ammonium sulphate), Merk's egg albumin and egg white (obtained from fresh eggs). It was found that artificially iodized blood serum (ox) causes acceleration of metamorphosis when fed to tadpoles, resembling that shown by thyroid, but not so marked nor so rapid. It is possible to show by crude process of separation that the globulin fraction of the serum contains most of the substance with which the iodin combines to give the activity of tadpoles. Alkaline hydrolysis of iodized proteins apparently destroys their activity, therein differing from thyroid. This suggests that the thyroid adds something to the iodin complex in the blood to complete the stable iodin containing thyroid hormone.

27. **Influence of Ergotoxin on Body Temperature.**—The facts reported by Githens seem to show that in many species ergotoxin exerts a specific influence on the heat-regulating center, disturbing the relation between heat production and heat dissipation. In cats and in rabbits this induces a rise of body temperature; in rats, mice and pigeons it causes a fall.

28. **Protozoocidal and Bactericidal Action.**—Emetin hydrochlorid in solution of 1:1,000 when acting on water amebas for one hour, or in solution of 1:5,000 acting for three hours, destroyed many of these organisms but was not uniformly amebacidal. Emetin hydrochlorid in solution of 1:200,000 in contact with cultures of amebas for one hour, four hours, or seven hours destroyed many amebas, but transplants from these cultures to fresh agar plates showed a retarded or delayed growth of amebas, owing probably to the development of encysted or resistant forms. Emetin hydrochlorid in solutions as strong as 1:100 are not rapidly destructive to the *Endameba buccalis,* in some cases not killing it in one hour. The propyl and iso-amyl ethers of cephaelin are stronger than emetin as amebacides but their action on water amebas or the *Endameba buccalis* cannot be used satisfactorily as a comparative measure of this action. Methylating

cephaelin to form emetin is known to increase the endamebacidal action as well as the protozoocidal action toward paramecia and the substitution of the methyl group by ethyl, propyl, butyl, iso-amyl or allyl further intensifies this action. The propyl, butyl and iso-amyl ethers of cephaelin possess much stronger protozoocidal properties than the methyl ether (emetin). Cephaelin iso-amyl ether phosphate was the most effective alkaloid of this group in killing paramecia, being fifteen to twenty times as active as emetin phosphate. Tested on *Staphylococcus aureus* in the manner described, cephaelin propyl ether phosphate is germicidal in solutions of 1:222, and cephaelin iso-amyl ether phosphate in solutions of 1:4,120. Both of these derivatives are much stronger than emetin in germicidal action.

29. **Changes in Purged Intestine.**—The well purged rabbit is likely to be apathetic and to look sick. Its bowel is full of gas and fluid, and the mesenteric circulation is disturbed. Excised segments beat poorly and irregularly in Locke's solution, and they fatigue quickly. They respond poorly to drugs. Some parts of the bowel are abnormally irritable while others fail to respond at all to powerful stimuli. This unevenness in the gradient of muscular forces must interfere with the steady progress of food through the intestine; and probably favors the production of colic and gas pains. The conclusion drawn by Alvarez and Taylor is that it is not wise to purge shortly before an operation in which the bowel must stand the insults of drying, handling, cutting and sewing.

34 New Universal Urethroscope with New Diagnostic and Therapeutic Fields of Application. L. Buerger, New York.—p. 495.

31. **Control of Diabetes Insipidus.**—Thus far, comparatively few cases treated by the injection of posterior lobe extract have been reported. The treatment of the patient, detailed by Barker and Mosenthal yielded results that did not differ appreciably from those reported by other authors who have injected posterior lobe extracts. The facts given may, therefore, be considered as confirming previous observations. The response of the kidneys to numerous injections was constant throughout. The most favorable effect was obtained when two or more injections of not less than 1 c.c. each, were given during the course of the day. This patient was made perfectly comfortable, and apparently the efficacy of the extract did not diminish over a period of four weeks' trial in the hospital nor after about one month's continuation of the therapy at home. The patient having once experienced the relief afforded by the injections refused to do without them. Tethelin and epinephrin do not seem to be of any value in the treatment of diabetes insipidus.

32. **Effect of Thyroid Medication on Basal Metabolism.**—The effects of thyroid treatment, as measured by clinical, renal function and metabolic studies, are reported by Bowen and Boothby in two cases of myxedema, complicated by symptoms of chronic nephritis, and in three cases of chronic nephritis in which there was no evidence of thyroid insufficiency. In the first group thyroid medication produced a marked improvement in the clinical and metabolic conditions together with some improvement in the renal function. In the nephritic cases, however, no improvement occurred from its use, and indeed in two cases decidedly injurious effects were produced. The authors state that although thyroid medication has been recommended as a means of satisfactorily treating cases of nephritis, is not indicated unless there is an associated condition of myxedema. The degree of thyroid insufficiency and the effect of treatment thereon can best be gaged by the determination of the basal metabolism.

84 *Analysis of Nine Hundred and Ninety-Eight Consecutive Complete Blood Counts. F. B. Utley, Pittsburgh.—p. 106.

84. **Analysis of Blood Counts.**—In the 998 blood counts made by Utley the polymorphonuclear leukocytes were increased over the accepted normal percentage of 70 in 179 smears. This increase was found in patients suffering from infections, acute or pyogenic. They were diminished under 65 per cent. in twenty smears without an abnormal increase in any other group of cells with which they might be classed. This diminution occurred in asthenic conditions, or in those patients who are regarded to have an abnormally low resistance. Of the 998 differentials made, there were eighty-eight which had an absolute eosinophilia or over 250 eosinophils per cubic millimeter. In fifty-one, or in 57.9 per cent. of the cases, eosinophilia did not assist in the diagnosis in the light of present knowledge. There was an eosinophilia in twelve cases of intestinal putrefaction, indicating a correlation of the chemotactic action of intestinal parasites and of intestinal putrefaction. Basophils in excess of 1 per cent. were present in twenty-six cases. The presence of basophilia was not of much help in diagnosis. In general, it was present in asthenic conditions. Myelocytes were present in fifteen cases. Twelve were patients suffering from pernicious anemia, one a patient suffering from angina pectoris, and two were patients whose condition was not diagnosed. Differentials showing lymphocytes in excess of 30 per cent. were regarded as showing a lymphocytosis. Practically all the cases fall within the prescribed list except those which could not be classified. There were 166 smears in which the large mononuclears were 5 per cent. or over.

The cases of syphilis, the various cachexias, malignant endocarditis, influenza, measles and Hodgkin's disease or twenty-three cases in all out of the 166 may be regarded as being in the usual group, leaving 143 cases or 86.2 per cent. of the cases ungrouped. In other words, in 86.2 per cent. of the cases the presence of large mononuclears in excess of normal can not be explained in the light of present knowledge. The asthenic group totals sixty-four cases, or 38.5 per cent. There were twenty-nine smears which showed so-called transitionals in excess of 5 per cent.. There were 272 normal counts, and these coincided with the clinical picture in each instance, except in a few cases of pernicious anemia and influenza where the differential might have been expected to be different. Adding to the 272 normal counts which were of no definite help in diagnosis, the undiagnosed cases in each group or 104, there were 376 counts out of the 998 made which had no direct bearing on the diagnosis, prognosis and treatment of the patient. Deducting from each group the number which had no classification in that group according to the light of our present knowledge, or 210, and adding these to the 376, there were 586 counts made which offered no direct assistance in the diagnosis, prognosis and treatment of patients. Of the remaining 412 counts the way to a diagnosis was pointed out in six of seven cases of intestinal parasites and in seventeen cases of pernicious anemia, or twenty-three in all. In the remaining 389 cases the blood count was helpful in diagnosis.

9 Acute Delirium in Lobar Pneumonia in Child. J. P. Parkinson. —p. 193.

7. **Congenital Defect of Duodenum.**—Cockayne's case occurred in a male child born at full term. There was no history of any similar condition in the family and the mother was in good health during her pregnancy. At the confinement it was noticed by the medical attendant that the liquor amnii was excessive in quantity and bright green in color. The child vomited liquid, which resembled the bile-stained liquor amnii, on the second day, and passed meconium of normal appearance. Slight jaundice was noticed on the third day. Vomiting continued at intervals, the vomit being invariably watery and green, but no more meconium was passed. The general condition became gradually worse until death took place on the fifth day. At the necropsy it was seen that the child was well nourished and without any external malformation. The skin was slightly icteric. On opening the abdomen the stomach was found to be greatly dilated and the first part of the duodenum to end blindly, being greatly distended and globular in outline. The pylorus was visible and palpable as a thickened constriction between these two organs. Some fluid stained with the bile was present in the stomach and distended first part of the duodenum. The bile-duct opened directly into the narrow commencement of the lower part of the duodenum, but the pancreatic duct entered the posterior aspect of the blind sac formed by the upper part of the duodenum. There was no connection except by peritoneum between the upper and lower portions of the duodenum; the missing part of the viscus was not even represented by a thin cord. The liver, gallbladder, cystic duct, hepatic duct, and common bile-duct were normal, and the gallbladder contained a considerable amount of bile. The most interesting feature of the case and one which made a correct diagnosis almost impossible, was the fact that a large quantity of bile-stained fluid was vomited, although the bile-duct opened into the lower part of the duodenum, and there was complete lack of continuity between it and the upper part.

Edinburgh Medical Journal

November, XIX, No. 5

10 *Lathyrism. R. Stockman.—p. 277.
11 *Lathyrism in Man. R. Stockman.—p. 297.
12 Case of Syringomyelia. D. M. Greig.—p. 308.

10. **Lathyrism.**—The results of many experiments on such animals, as the monkey, rabbit, pigeon, duck, pig and sheep made by Stockman showed that both the large peas (grown on dry wheat lands) and the small peas (grown on wet rice lands) of *Lathyrus sativae* are poisonous, but different samples

of peas vary greatly in toxicity. The poisonous substance is an alkaloid. Certain species of animals are very much more susceptible than others. Individual susceptibility varies greatly in the same species. With ordinary samples of the peas and in susceptible animals feeding has to be carried on for some time before toxic symptoms develop. Occasionally, however, the peas seem to be more poisonous and capable of causing more acute poisoning. In monkeys and in other susceptible lower animals prolonged feeding seems to cause a greater or lesser degree of paralysis of the peripheral nerves, along with other symptoms due apparently to an action on the central nervous system. A single large dose of the alkaloid paralyses the terminations of motor nerves, but other parts of the nervous system are also affected. Histologic examination of the muscle and nervous system in poisoned monkeys showed no structural changes.

11. **Lathyrism in Man.**—Lathyrism in man is a chronic nervous disease due to the habitual use as food of the peas of certain species of *Lathyrus* (vetchlings); it occurs endemically and epidemically. The symptoms appear only after the peas have been eaten for some time, the length of time varying according to the quantity consumed and the amount of poisonous alkaloid present. Individual susceptibility also appears to have a considerable influence as only certain persons in communities and families suffer, even when all are apparently equally exposed. A striking feature in every epidemic has been the large number of men affected as compared with women, generally estimated as ten or twelve to one. Two explanations of this have been given, the one, that men habitually eat more than women, the other, that men are more exposed to cold and wet and fatigue, conditions which seem to accentuate the action of the poison.

The patient first complains of cramps in the calves of his legs, and if he then stops eating the grain he may recover almost entirely, or only a little stiffness of his legs may remain. He is able to walk about without the aid of a stick, but an up-and-down movement of his shoulders may be noticed when he is walking. His toes may drag slightly on the ground. If he continues eating peas he may experience a somewhat sudden onset of paralysis. If he still eats peas he will lose control over the bladder and rectal sphincters. A very small number of patients are unable to stand even with the aid of sticks. The knee jerk is increased in all cases, sometimes more on one side than on the other, and the foot clonus is increased only in the severe cases. The muscles in the back of the leg are rigid. The muscles were found, as a rule, to be well nourished. Bed-sores were never seen. The paralysis of the sphincters passes off in a few weeks; sexual power is diminished or lost, but it may return. Sensory symptoms precede the paralysis, chiefly cramps, a feeling of tightness in the leg tendons, tingling, pins and needles and weakness at the waist. The gait is characteristic.

In the mild case the patient has to raise his body high before the toes will leave the ground, and the up-and-down movement of the shoulders is the chief symptom noticed. In the more severe cases the patients use one or two sticks, and these sticks are always long. One stick is put forward and then the upper part of the body sways forward; the body becomes erect before the other stick is put forward. The dragging of the toes is the most marked symptom. The inner side of the nail of the great toe is worn away, and in bad cases the upper surface of the outer toes may be rubbed. There is nearly always a tendency to cross legged progression. No satisfactory examination of the spinal cord and peripheral nerves has ever been made. Treatment is generally said to be futile if the disease is fully developed.

19. **Transmission of Plague by Bedbugs.**—Cornwall and Menon point out that bugs which have fed on a case of septicemia plague must unquestionably be regarded as ambulant cultures of plague whose rupture will set free virulent plague bacilli. A large proportion of the bugs infected with a given strain of *B. pestis* succumbed in a few days, the time of survival having some relation to the dose of bacilli. If bugs died the final results were indistinguishable whether the initial dose were large or small. The majority of the survivors had entirely overcome their infection and contained no viable bacilli. Some common nonpathogenic bacteria are as fatal to bugs as the most pathogenic. Bugs with a bacterial infection generally refuse to feed for a long time. A sterile refeed, if the infection has not been entirely overcome, may lead to a fatal recrudescence. *B. pestis* can survive in the stomach of a bug, which has had one or more sterile feeds after the original infected feed, for at least thirty-eight days. *B. pestis,* recovered by culture from the stomach of an infected bug, retains its virulence for guinea-pigs. Peculiar protozoon-like involution or developmental forms of *B. pestis* may be seen in preparations from the stomachs of infected bugs. All attempts to obtain a growth of *B. pestis* by allowing infected bugs to feed on a sterile fluid through a rabbit skin membrane failed. All attempts to transmit plague to guinea-pigs by means of the bites of infected bugs failed. *B. pestis* sometimes finds its way from the stomach of a bug into the hemic cavity and thus produces a true septicemia. Infected bugs may die from toxemia before the occurrence of septicemia. *B. pestis* may be recovered by cultivation of the proboscis of a bug in broth within an hour of its infected feed. The presumption is that bacilli which have been stranded in the sucking tube multiply in the culture medium. Pressure on the body of a fed bug will not force the contents of its stomach out along its sucking tube. After an infected feed the proportion of bugs which can be expected to feed within a few hours on a normal animal and at the same time to have bacilli stranded in their sucking tubes is not likely to exceed 2 per cent.

24. **Parasite in Human Intestine.**—A flagellate was found by Chatterjee in the stool of a dysentery patient. No amebas were found in the stool. The patient suffered from intestinal complaints for a week and obtained relief by administration of castor oil emulsion. A cover-glass preparation made from the stool showed under the high power a large number of actively moving flagellates. Their appearance differed from the flagellates which are ordinarily found here, namely *Lamblia, Pentatrichomonas* or *Macrostoma.* Some of the flagellates were circular in shape. The flagellate resembles a *Trichomonas* but absence of an undulating membrane, a well marked axostyle and a tail prove that it is not a *Trichomonas.* It has some resemblance to *Copromastix prowazeki* of Aragao which has four flagella, but in the latter all the flagella are directed forward, whereas in the parasite under consideration one flagellum is directed backward. It has the structure of *Trichomastix* as defined by Parisi (three anterior flagella and one recurrent flagellum not adherent to the body to form an undulating membrane). As a *Trichomastix* inhabiting the human intestine has not hitherto been described, Chatterjee feels justified in describing it as a new species *Trichomastix hominis.*

35 Digestibility of Bread Made from Two Parts of Wheat and One Part of Oats, Barley, Maize or Rice. E. I. Spriggs and A. B. Weir.—p. 724.

29. **Gunshot Wounds of Chest.**—An analysis made by Rudolf of fifty cases shows that evidence is lacking that small fragments of shell and shrapnel and likewise rifle bullets and shrapnel balls retained in the lung commonly give rise to any serious trouble. The mortality of gunshot wounds of the chest in patients that have survived the early days of their invalidism and been sent to England with retained missiles in the chest is practically nil if these foreign bodies be left alone. Hence, when it has not been considered necessary by the surgeons at the front to operate immediately, it should not be done later on, unless, indeed, some very definite indication, such as an abscess, exists.

30. **Abnormal Nerve Supply in Hand.**—Harris has seen four cases of abnormal nerve supply to the hand, two of the sensory distribution and two motor. In two cases the first and second dorsal interossei were quite unaffected in severe ulnar nerve lesions from gunshot wounds, indicating their supply to be from the median nerve in these cases, while the other two cases illustrated an abnormally large sensory supply by the ulnar to the inner two and a half fingers instead of the usual one and a half.

31. **Cerebrospinal Fever.**—Observation of a number of cases has convinced Worster-Drought and Kennedy that the mode of entry of the meningococcus is via the blood stream. In the ordinary type of case the coccus is carried to the meninges by the blood within a few hours without definitely infecting the blood itself. In some cases, however, blood infection (septicemia) occurs, for instance, in fulminating cases prior to the involvement of the meninges; the septicemia then frequently overshadows the meningitis. In rare cases the organism may remain, infecting the blood alone for a considerable time, before finally reaching the meninges, or the patient may die of such septicemia before meningitis can occur. In other instances the meningococcus infecting the blood may also invade structures other than the meninges, for instance, the cardiac valves. Catarrhal conditions predispose to meningococcal infection, but the meningococcus does not necessarily produce nasopharyngeal catarrh.

32. **Action of Spinal Fluid on Meningococcus.**—The main outcome of Shearer's experiments is to show that there is present in normal spinal fluid some substance that greatly increases the rate of growth of the meningococcus on an artificial culture medium. They demonstrate that this power, in the case of human spinal fluid is relatively greater than that shown by blood or nasal secretion; that volume for volume, spinal fluid brings about a much thicker growth of the meningococcus than do the same volumes of blood or nasal secretion.

41 Hemiplegia from Concussion of the Spinal Cord. G. Roussy and J. Lhermitte.—p. 458.

36. **Testing the Heart.**—Vaquez and Donzelot refer to tests for military service, emphasizing that the usual tests do not take into account all of the four main factors in the acceleration of the pulse after a test running or stair-climbing exercise. The irritation of the accelerating nervous system, the reduction in the peripheral resistance, the hampering of the diastole and hence the incomplete filling of the ventricles, cooperate with the hampering of the systole to modify the pulse, but only the difficulty with the systole is directly connected with the force exerted by the myocardium itself. In their examination of hundreds of men in the last few months they were impressed by the extreme variety of the tracings in different persons and at different times in the same person. Also with the frequent contradiction between the tracings which seemed to give most favorable testimony and the unmistakable grave clinical symptoms in certain cases. It seemed impossible to determine any definite relations between the different types of tracings and curves and the functional capacity of the heart. They discuss each type of curve in turn, their conclusions being that the only way to estimate the reserve force of the heart and hence its functional value is to make a careful clinical examination in each case, completed by sphygmomanometry and radioscopy. The men with well compensated mitral or aortic incompetency can be passed for merely the auxiliary service (light duty); as also those with pericarditis with merely localized adhesions. All other forms of cardiac or aortic lesions justify exemption. With functional cardio-pulmonary trouble, the right heart intact, light duty only. In regard to arrhythmia, they state that breathing arrhythmia is not pathologic. With extrasystolic arrhythmia, young men should be passed for full military service with progressive exercise, but older men should be passed only for the auxiliary service or should be exempted, according to the size of the heart. With paroxysmal tachycardia without valvular lesion, the men should be given a rest in a hospital at the front with convalescence leave. With tachycardia in general, the man should be kept in bed for three or four days and then reexamined from time to time. If the tachycardia subsides under repose, progressive exercises are then in order.

39. **Sequels of Pleural Effusions.**—From clinical and radioscopic study of 152 cases of traumatic and spontaneous disease of the pleura, Péhu and Daguet state that months and years afterward there was extensive adhesion of the sheets of the pleura, over extensive areas, only in the cases of pleurisy of tuberculous origin. In all the other cases the adhesions were slight or transient as a rule, including the cases with simple hemothorax after a war wound. Extensive hemothorax persisting after several punctures is liable to produce symphysis between the sheets of the pleura, the same as hemothorax of the dura, as it undergoes organization. Radioscopy reveals the extent of the symphysis and its influence on respiration.

40. **Proteolytic Power of the Leukocytes.**—The proteolytic power of the leukocytes in pus has been well studied, but Fiessinger and Clogne here report what they think is the first extensive research of the kind on the normal polynuclear leukocytes in the blood stream. They found that these leukocytes secrete a protease that has the same action as the protease of the pus leukocytes, an action resembling that of trypsin. The findings are tabulated in detail. They isolated the leukocytes for the purpose by hemolyzing with diluted alcohol and centrifuging.

46 Present Status of Treatment of Fractures. Stassen and J. Voncken.—p. 416.

42. **Rigidity of the Abdominal Wall with War Wounds.**—Willems expatiates on the importance of determining the presence and degree of rigidity of the abdominal wall in

case of wounds anywhere on the trunk. Even with wounds on the limbs near the trunk, we may overlook important information if we neglect to determine the condition of the abdominal walls. The rigidity may be partial, localized, or there may not be absolute rigidity. With much hemorrhage in the abdomen, the rigidity is general and pronounced; with hemorrhage in the thorax there is also a certain amount of rigidity even when the diaphragm is intact, as also with retroperitoneal lumbar hemorrhage with or without injury of the kidney. The peritoneum is not inflamed, but it is pushed out of its normal place by the accumulation of blood forcing down the diaphragm or in the lumbar region, hence the muscle over it contracts but not so taut as with peritonitis.

When the peritonitis reaches the stage of sepsis, the abdominal wall relaxes. This is liable to be misleading when the patient with a lesion of some hollow viscus is not seen until the rigidity at first has subsided into the stage of relaxation. In some persons the wall is less board-like than in others, and the rigidity is much less pronounced with simple hemorrhage than with perforation of one of the viscera. Small intraperitoneal hemorrhages do not induce rigidity until considerable blood has accumulated, and then only the muscle wall in this region contracts. With a war wound in the liver, there is no rigidity as the blood flows a little at a time. It settles in the right flank; and when enough has accumulated there is rigidity, but only in the right flank. The wound in the liver may be small and heal spontaneously, but the "wooden abdomen" always calls for a laparotomy. With a rapidly developing hemothorax, that side of the abdominal wall stiffens, especially the upper part, and the assumption that the projectile has entered the abdomen seems justified. But by waiting a little, keeping the man quiet, we find the rigidity less pronounced by the next day and all gone in a few days. This unilateral rigidity of the abdomen has led to many unnecessary and futile laparotomies. With a wound of the kidney, the rigidity is likewise unilateral, and some part of the wall on the other side can always be found normal. If the hematuria is not menacing, repose may be all that is needed; otherwise the kidney should be removed from the rear. The abdomen should not be opened for unilateral rigidity. The kidney often is wounded with the peritoneum still intact. With wounds in the pelvis region alone, the rigidity is localized in the vicinity and subsides in a few hours. The partial, localized rigidity only renders more significant the necessity for a prompt laparotomy when the whole abdominal wall is rigid. As Willems expresses it, *grande défense* calls for intervention, and *petite défense* for abstention.

43. **War Psychoses.**—Hoven's conclusion from 300 cases are that the psychoses encountered in the men at the front are the same old types known during the days of peace.

44. **Local Treatment of Diphtheria Bacilli Carriers.**—Roskam reports that local treatment of the throat with iodin and other antiseptics did not clear the throat of bacilli by any means as effectually as when they were treated by insufflation of pulverized antitoxin. With the latter the carrier period was shortened by 33 per cent. in the convalescents from diphtheria and by 59 per cent. in the healthy carriers. The antiseptic group included 53 convalescents and 28 healthy carriers; the antiserum powder group 49 convalescents and 65 healthy carriers. In this last group all but 4 of the convalescents lost their bacilli on an average before the twenty-second day; all but two of the carriers before the nineteenth day.

47. **Autoreeducation of Disabled Soldiers.**—Le Dantec has noticed that the men overcome their disability with exceptional ease when the training combines simultaneously both active and passive movements. For example, with total hysteric paralysis of the arm, he takes up one finger, stretches it at the word "One" and flexes it at "Two," repeating this five or six times, the patient exerting his will at the same time to the utmost to extend or flex the finger at the word of command. He does the exercise first on the sound hand, the volitional and the passive movement exactly synchronous, until he gradually reduces the passive force to zero. In the same way, on the disabled hand, after five or six repetitions, there can generally be seen a suggestion of volitional movement in the finger. Each finger and finally the hand and the arm are thus exercised separately. The thumb and big toe usually regain spontaneous movement first with this "conjugated bipolar training," as he calls it. Neither the will alone nor the passive movement alone can accomplish this rearousing of function, but the cumulative action of the two combined is proving very successful in his service. He first softens the tissues by soaking in tepid water and massages with greased or soaped hands. Progress is hastened when the man is taught to do the passive movements himself with the sound hand. This gives a zest to the exercises as volitional control is regained, and the man keeps himself busy repeating these auto-exercises. In his service the men sit at a long, covered table and rest the bare arm on it. They stand when the shoulder is being exercised, and sit with bare legs when the paralysis to be combated is in the leg. As soon as spontaneous movements are possible, the men can be allowed to go home, continuing their exercises at home, returning every three weeks to report progress.

48. **Pneumonia in Prison Camp.**—Mallié relates that in the Alten-Grabow prison camp (Prussia) in the course of eleven months there were 244 cases of frank pneumonia with ten deaths among 1,200 French and Belgian prisoners of war, and 116 cases with eleven deaths among an equal number of Russian prisoners. In describing these experiences with pneumonia in the debilitated war prisoners, he emphasizes that pneumonia damages the pleura much more than is generally recognized, thus predisposing it to invasion by the tubercle bacillus. Courses of tonics and respiratory exercises should always follow pneumonia.

59 Secondary Aseptic Hematuria. E. Roucayrol and L. Bovier.—p. 332.

51. **The Urea Constant in Surgery.**—Legueu and Chabanier reiterate that the unfavorable outcome of many an operative intervention might have been foreseen if more attention had been paid to the functional capacity of the kidneys before attempting it. Aside from acute postoperative nephritis—which we have no means of foreseeing—we are able to determine the urea-secretory constant and maximal concentration, and thus obtain insight into conditions that warn of impending postoperative uremia. The danger from this, they explain, depends on the postoperative oliguria. Where the oliguria is not intense and does not keep up long, the uremia does not reach a menacing degree. Ambard's constant is a reliable index, they say, of the functional value of the kidneys from the surgeon's standpoint. It reveals the reserve functional power of these organs, and the surgeon is thus able to compare it with the task he is about to inflict on them, weighing along with it the general condition and degree of infection. It may warn to postpone the intervention until the patient is better able to stand it, or to operate under regional rather than general anesthesia.

52. **Deceptive Subsidence of Uremia.**—Castaigne calls attention to the misleading findings in chronic nephritis with a tendency to uremia when hydremia develops. The blood find-

ings suggest that the urea content of the blood is approaching normal once more, but this is deceptive. The change is due to more water in the blood diluting the urea, while the absolute amount in the circulating blood is the same or higher. In one of several cases reported, the hydremia was the result of a long course of mineral waters. In another, the hydremia followed return to salt in the food after restrictions on account of retention of nitrogen and sodium chlorid. The man of 34 died in coma in three months. The urea content of the blood was only 0.5 gm., but the reds numbered only 2,600,000, testifying to the hydremia which masked the uremia.

66 *The Laws on Industrial Accidents and War Wounds. L. Imbert.—p. 591.
67 Technic for Operations on the Calf. H. de Gaulejac.—p. 595.

60. **Bone Flap for Skull Defect.**—Sicard and his co-workers report forty-two cases in which they implanted a plate of bone from a skull to close a gap in the skull. The inner surface of the sheet of bone is scraped down to the diploic tissue and is fenestrated. It is then fitted over the gap like a watch glass, between the periosteum and the bone all around the gap. In three cases the plate had to be removed, and it was found that it had stimulated bone production until the gap was well on the way to being permanently closed by a new formation of bone. The findings show that the new growth is the work of the periosteum taking up from the dead bone the material it needs. This exaggerated osteogenetic power conferred on the periosteum testifies to the superiority of a bone flap over metal or other material for the purpose, to say nothing of the perfect tolerance and inexpensiveness of this technic.

66. **Pensions for Effects of Industrial Accidents and War Wounds.**—Imbert discusses the perplexing questions liable to arise when an industrial accident affects a man already damaged by a war wound, or vice versa.

Revue de Mêdecine, Paris

XXXV, No. 5-6, pp. 281-406

68 *Fat in Chest Wall as Sign of Disease Below. L. Landouzy.—p. 285.
69 *Rôle of the Pancreas in Glycolysis. R. Lépine.—p. 289.
70 Traumatic Neuroses after War Wounds. J. Ferrand.—p. 293. Commenced in No. 4, p. 239.

72 Delirium of Revindication and Hysteria. R. Benon.—p. 331.
73 The Skin Diseases of War. H. Gougerot.—p. 342. To be continued.

68. **The Adipose Tissue in the Chest as Aid in Diagnosis.**—In this last article from Landouzy's pen, he calls attention to the extra fat in the chest wall liable to be encountered over an old or active pleural or pulmonary lesion. He takes up a fold in the skin as if to apply a seton. The thickness of this fold compared with a symmetrical fold may prove instructive, as the adipose tissue is thicker over the diseased portion. The innervation of the adipose tissue here does not function normally, and the fat does not get oxidized properly. Not being normally oxidized, the fat accumulates. In the cases cited the fold was 13, 18 or 19 mm. thick over the apical lesion in the pectoral region while it measured only 10 mm. on the sound side. In a man of 46, four years after an attack of pleurisy, the chest seemed symmetrical but the calipers showed the fold to be 22 mm. thick over the site of the old pleurisy and only 16 mm. on the other side. In a young man ten weeks after the onset of pleurisy, the overlying fold measured 19 mm. to 10 mm. on the other side.

69. **Pancreatic Diabetes.**—Lépine protests against incriminating the pancreas alone in glycolysis. Certain others of the glands with an internal secretion are unmistakably involved likewise in the glycolysis process.

Correspondenz-Blatt für Schweizer Aerzte, Basel

October 20, XLVII, No. 42, pp. 1393-1424

74 *Indirect Trauma as a Factor in Aneurysms of the Basal Arteries of the Brain. E. Hedinger.—p. 1393.
75 *Errors in Deductions from Presence of Lactic Acid in the Stomach. A. Rodella.—p. 1398.
76 *Concussion and Shell Shock Psychoses. L. Binswanger.—p. 1401.

74. **Trauma and Aneurysms of Basal Arteries.**—Hedinger reports a case similar to that published by Saathoff in which indirect trauma induced rupture and aneurysm in the basal artery of the brain without a trace of inflammatory processes in the vessel wall. His patient was a woman of 47 who had fallen down a flight of steps four years before and had since complained of pains in the back of the neck and head in addition to her preexisting tendency to migraine. She died suddenly and necropsy revealed aneurysm of the vertebral artery with no signs of inflammation. The vertebral and basilar arteries seem to be unusually predisposed to aneurysms. In Hedinger's experience, the Wassermann reaction was always positive in the cases that came to necropsy, the ages between 25 and 40. There is much to sustain the assumption that even slight trauma, such as the forcible stretching of the spine, might damage slightly the posteriór cerebral arteries and thus afford a favorable field for colonization by the pale spirochetes.

75. **Lactic Acid in the Stomach.**—Rodella states that the Uffelmann reaction is not specific for lactic acid, but is a group reaction for the group containing citric acid, tartaric, oxalic and succinic acid besides lactic acid. Lactic acid may be found in the stomach content without lactic acid bacilli, and vice versa. He relates further that native albumin, blood or serum, is an indispensable condition for abundant lactic acid fermentation. If there is ulceration or blood in the stomach, there will be profuse production of lactic acid even when the stomach is being emptied normally, provided there is little or no hydrochloric acid present. Time must be given for the fermentation; the findings in less than three quarters or a full hour are misleading. Microscopic discovery of lactic acid bacilli is much more reliable than determination of lactic acid alone.

76. **Concussion Psychoses.**—Binswanger analyzes some of the cases of shell shock psychoses in disabled soldiers interned in Switzerland. In the small group studied all the men had had wounds of the frontal lobe. Some required two operations, and they developed psychoses of a different type after each.

Riforma Medica, Naples

77 *Pathogenesis of Paralysis or Contracture after War Wounds. A. Salmon.—p. 993.
78 Introduction of Antimony into Treatment of Internal Leishmaniosis. R. Jemma.—p. 1007.

77. **Pathogenesis of Paralysis and Contracture.**—Salmon reviews the recent publications of neurologists in this field, and insists on the importance of prolonged immobilization in perpetuating the tendency to paralysis and contracture. He does not admit, however, that this alone is responsible for them. It cannot explain the special vasomotor instability nor the lively reactions on the part of the nerve centers. This vasomotor instability in the region of traumatic neuroses of the hysteria type is too often overlooked. Among the examples cited is the case of a soldier who has had hysteric tremor in the right leg since a war wound. The tremor comes on every time the leg is examined and it becomes actual clonus at the slightest bending of the foot. Along with this there is pronounced dermographism and the skin grows as red as in measles, all coming on and subsiding with the tremor in the leg. The direct connection between the vasomotor phenomena and the hysteric is thus plainly evident. There are many cases on record of simulation of paresis or contracture in which hysteria intervened and rendered it permanent. As he remarks, "the hysteric simulate with the complicity of their organism, and they are left victims of their intent to deceive." Psychotherapy alone is ineffectual

unless supplemented by massage, passive and active exercises, etc. The great obstacle to recovery is the apathy or direct disinclination for recovery. Moral suasion may rouse the men to help themselves get well, threat of punishment, or loss of pension if the physician's efforts are not seconded. With such psychic and physical revulsion excellent results may be obtained. The main point is to begin treatment early and vigorously and not allow immobilization to be kept up too long.

Cronica Medica, Lima

83 Present Status of Leishmaniosis. E. Escomel.—p. 334. To be continued.

79. **Trypanosomes at Lima.**—Ribeyro and Raffo report that they found the *Trypanosoma duttoni* in three mice out of a hundred examined. The infected mice came from different houses.

80. **Hyperchlorhydria from Biliary Trouble.**—Robles agrees with Pauchet's recent statement that, on an average, of every ten persons with gastric disturbance, in nine the dyspepsia is of reflex origin, the actual source of the trouble being located outside of the stomach. He reports some typical cases in which everything seemed to indicate stenosis of the pylorus or cancer of the stomach until the whole set of symptoms subsided under medical or surgical treatment of a liver abscess or gallstones, or sluggish liver functioning. In one case nothing could be found at first to explain the gastric pains and other symptoms of hyperchlorhydria from which the woman had suffered for four years. Finally palpation was done as she stood erect. This revealed a tender point in the biliary apparatus which could not be palpated when she reclined. Under treatment to stimulate the production and flow of bile, complete recovery soon followed. Unless bile is being normally secreted and passed along, the pancreatic juice does not get the stimulus which insures its passing into the stomach after a meal. This leaves the gastric secretion in its full strength, not neutralized as normally by the strongly alkaline pancreatic juice. The normal interplay between these three secretions is thus interrupted, and the hydrochloric acid in the stomach exerts an abnormal corroding action. This explanation fits a certain proportion of cases of hyperchlorhydria, and the biliary apparatus should be definitely excluded before incriminating other factors.

88 *Action of Animal Charcoal on Extracts of Organs. B. A. Houssay.—p. 151.

85. **Tuberculous Process in Submaxillary Gland.**—Landaburu knows of only two cases on record of what he calls bacillary submaxillaritis, but two have been encountered in Vigas' service among 22,000 patients. He gives the microscopic findings in a case in a girl of 14. No tubercle bacilli were found in the giant cells of the tumor after its removal, but the findings otherwise were typical.

87. **Normal Beef Serum in Treatment of Anthrax.**—In this third communication on this subject, Kraus and his co-workers give illustrated descriptions of some of the seventy-eight cases of their latest series of cases of anthrax subsiding under the subcutaneous injection of from 10 to 50 c.c. of normal beef serum.

88. **Adsorption by Animal Charcoal of Active Principles of Organ Extracts.**—Houssay relates that the active principles of pituitary extracts, epinephrin, etc., are adsorbed by animal charcoal and *cannot* be recovered from it with cold or hot water or glycerin. Scorpion and snake venom are adsorbed in the same way, and talcum, kaolin, etc., display similar absorbing properties.

96 *American Leishmaniosis. H. Quintana and J. B. Etcheverry.—p. 382.

89. **Grafted Epiphysis of the Humerus.**—Arana's patient was a young man who had fractured the surgical neck of the humerus in a fall from a horse. The extremity of the humerus was taken out and wrapped in gauze during the surgical clearing out of the region. The epiphysis was then restored to place, the lower stump fitting into the lower end of the ingrafted epiphysis. The bed for the lower stump was hollowed out as the epiphysis lay on the table. It was then fitted on the exposed and projecting shaft, and the whole was reduced and the capsule sutured. Roentgenograms taken at intervals since show production of new tissue in a most satisfactory manner. The young man has the practically free use of his arm; only abduction is limited, and this is constantly growing better.

90. **Boiling Water Injections in Local Treatment of Exophthalmic Goiter.**—Six cases of exophthalmic goiter are reported in which the women, from 18 to 52 years old, were treated by systematic injections of boiling water into the goiter according to Porter's technic. Each one was materially improved, the symptoms becoming much attenuated or disappearing altogether. The earning capacity in each was restored, and none of the symptoms have returned during the months to date. The writers do not venture to speak of a complete cure, but they declare that at least with this simple means it is possible to induce material improvement. Some of their patients were given this boiling water treatment to prepare them for thyroidectomy, but the improvement was such that further intervention did not seem necessary. The microscopic findings are given in one case in which part of the gland was excised later. They show that the boiling water had accomplished its purpose, inducing sclerosis and proliferation of connective tissue with destruction of the glandular tissue. Some of the patients were given up to thirty injections.

91. **Perforation of the Uterus.**—Cirio and Leiva analyze five cases, showing the especially susceptible regions of the uterus and the indications for treatment. In one of their cases the perforation was not suspected until the fluid with which the uterus was being rinsed failed to return. In this and similar cases they proceeded at once to posterior colpotomy which permitted evacuation of blood and other fluids and ample drainage. When there is suspicion of injury of the intestine or omentum, a laparotomy is indispensable. Their patients all promptly recovered except in the one case of perforation from criminal auto-abortion.

94. **Synovial Cysts.**—Finochietto relates that recurrence of synovial or parasynovial cysts is disappointingly frequent whatever technic has been used in treating them, and he attributes it to the technic generally used, namely, ligation of the assumed pedicle of the cyst. In reality these cysts do not have a pedicle. The secreting inner surface of the cyst can be removed, with all its prolongations and extensions, in one piece if done with care. What is supposed to be the pedicle is merely adhesions which can be cut or broken without injury to the subjacent tissues. Puncture alone may be sufficient to cure in certain cases. In order to liquefy the contents, he injects 0.5 c.c. of solution of potassium hydroxid when the contents cannot be aspirated readily. He then

aspirates the contents with a broad needle; then injects more of the solution and aspirates anew, until finally convinced he has cleared out the cyst completely. The caustic solution must be introduced very cautiously so that none gets into the tissues around. He uses two needles, introduced on opposite sides of the cyst, the finer needle for the caustic solution, the coarse needle for the evacuation. When this aspiration alone does not cure the cyst, he injects some caustic to destroy the secreting lining, and has found very useful for this purpose a mixture recommended for hemorrhoids, namely, 8 gm. phenol; 4 gm. sodium biborate; 2 gm. salicylic acid, and 30 gm. sterilized glycerin. The first injection should not be more than 0.5 c.c. to see how the tissues stand it. Extirpation of the cyst is the last resort when all these measures fail.

95. **Normal Beef Serum in Treatment of Anthrax.**—Lignières has been unable to confirm the assertions of Kraus and Penna in regard to the curative action of normal beef serum in treatment of anthrax. He reports extensive experiments, all apparently proving his contention that the others have been misled in their statements as to its efficacy. One of his arguments is the prevalence of natural anthrax in cattle; if their serum possessed any natural defensive properties it would seem as if their serum would protect them against the disease. He asserts that if normal beef serum had a therapeutic action in Kraus' experiments and clinical experiences, a prepared immune serum would have been correspondingly more effectual.

96. **American Leishmaniosis.**—Quintana and Etcheverry state that two years ago they encountered a peculiar ulcerating affection of the shoulder in a man. It was revealed by the microscope to be the work of Leishman bodies. A few months ago in the Tucuman district the first case of leishmaniosis was diagnosed. Since then a number of cases have been differentiated. They give illustrated descriptions of ten cases, and expatiate on the prompt and effectual action of antimony and potassium tartrate in treatment. The primary lesion is always said to be some small irritation, such as might well have been caused by the bite of an insect, as it is always on exposed portions of the skin. They emphasize the points which distinguish the leishmania from syphilitic lesions with which it might easily be confused, especially as it is not always possible to find the Leishman bodies in the lesions at the time of examination.

97 *Pyelonephritis of Pregnancy. L. F. R. Molina.—p. 505.

97. **Pyelonephritis of Pregnancy.**—Molina credits to Rayer of Paris, 1841, the first description of the pathologic relations of pyelitis with the enlarging uterus. Albarran advocated catheterization of the ureters and rinsing out the kidney pelvis when conditions did not right themselves at once after delivery. Widal and Achard in 1912 cultivated from the blood the same germ found in the urine. Molina has found in several cases that the women had had similar attacks in former pregnancies. The colon bacillus is generally responsible for them, some obstruction in the intestine rendering the walls temporarily permeable for the colon bacillus. The pyelonephritis of parturients is usually traceable to the streptococcus or staphylococcus. In the first of the five cases reported, the high fever, severe pain in the right lumbar region, spreading forward, and the vomiting, nearly all completely subsided after catheterization of the right ureter. Nearly three weeks later the same symptoms returned as severe as before, and this time it proved impossible to introduce the catheter and a twin miscarriage soon followed. The ureter had evidently been compressed by the gravid uterus. This assumption of compression of the ureter is confirmed by a case related in which the woman supposed herself at the sixth month of her fourth pregnancy when the symptoms of left pyelonephritis developed suddenly with anuria. Catheterization of the ureter arrested the symptoms but they returned in a few days, yielding anew to the catheter. At the third recurrence, catheterization was impossible. The assumption of a pregnancy was disproved and a laparotomy disclosed a sarcoma in the broad ligament.

This nonpregnancy case was the only one of the five reported in which the disturbance was on the left side. The case shows further that a tumor can induce pyelonephritis from mere compression of the ureter without involving it in the growth. The other three cases were in parturients and all were clinically cured at once by catheterization of the ureter, leaving the catheter in place for one or twenty-four hours. He mentions that urine is not found in the ureter in these cases of assumed compression. The catheter has to enter the kidney pelvis before it reaches urine; this seems to sustain Marion's theory that the ureter yields and slides aside before the enlarging uterus or tumor and its direct compression is not possible. Molina compares further the clinical pictures of puerperal fever and of pyelonephritis. With the latter the temperature generally runs up suddenly quite high with morning remissions and there may be chills, but the general condition keeps good except for the symptoms from habitual constipation and the constant albuminuria.

102 Relations between Radium and Phosphorus. V. F. de Courmelles. —p. 323.

98. **Helminthiasis at Buenos Aires.**—Parodi and Widakowich report that among 300 hospital patients, 74 per cent. of the children and over 54 per cent. of the adults were found harboring helminths. There was more than one variety in over 28 per cent. of the children and over 14 per cent. of the adults. No symptoms from them were apparent in most of the cases, but it is evident that neglect to examine for helminths is responsible for the difficulty in clearing up the diagnosis in many cases.

100. **Tests for Novocain.**—Sanchez is professor of analytic chemistry at the University of Buenos Aires. He describes a number of means to identify novocain, and to estimate the purity of a specimen. He determines the latter by dropping a 0.2 per cent. solution of the novocain into a solution of 0.8 gm. bromin in 1,000 c.c. water. When pure, the novocain solution decolors a certain volume of the bromin solution.

103. **"Albumin Phosphate" in Infant Feeding.**—This is the name given by Danilevsky in 1901 to the precipitate thrown down when milk whey is treated with ammonia. It takes about a gallon of fresh pure milk to make 40 gm. of the "albumin phosphate."

104. **Pituitary Extract in Treatment of Incontinence of Urine.**—Mikhailoff reports nineteen cases of nocturnal incontinence in children and adults in which prompt benefit followed treatment with pituitary extract in some form. This seems to have an elective contracting influence on unstriped muscle fibers and, as the bladder sphincter is composed of unstriped muscle fibers, a favorable influence on incontinence of urine might be anticipated from its action. The success surpassed his highest anticipations. All the patients were relieved of their incontinence, including ten children who had no other known anomaly, a few young men who had incontinence both day and night, and five or six men of 38 to 42 with exclusively nocturnal incontinence. One man of 28 had been unable to retain his urine at night since the age of 16.

Nothing decidedly pathologic could be discovered in the urogenital organs. After four weekly injections of the pituitary extract he was able to retain his urine at night. The patients have been under observation for three or four months and there has been no recurrence of the incontinence to date in any of them. Mikhailoff does not wait for more extensive experience but hastens to call attention to this harmless and effectual means of relieving young and old from nocturnal incontinence. Time alone will show whether the results will be permanent.

114 *Recovery of Two Children from Meningococcus Meningitis. A. Schoondermark.—p. 976.

110. **Tuberculin Reaction in Diagnosis and Treatment.**—Van de Kasteele presents arguments to show that as the skin plays a very active part in the diagnosis of tuberculosis, it probably aids proportionately in the treatment of tuberculosis when the tuberculin is given intradermally. He points to the rarity of serious forms of tuberculosis in children with tuberculous lesions of the skin. The skin foci seem to immunize the child against severe general infection. Wichmann has reported a case in which pulmonary and laryngeal tuberculous lesions subsided and the patient recovered after lupus developed, consecutive to a tracheotomy. It is possible that from the local focus which we make with our injection of tuberculin, antibodies are generated and thrown out into the circulation. The absorption from this focus of toxic substances which might injure the primary tuberculous focus is probably prevented by their destruction at the point where they are produced.

111. **Mixing of Drugs.**—Van Leeuwen writes from the Pharmacology Institute at Utrecht to protest against recent publications by Bürgi and others to the effect that the potential energy of certain drugs can be enhanced by combining them. Practical experience to date has not confirmed their theoretical premises, he says.

112. **Epidemic Meningitis.**—Hagen relates that lumbar puncture gave positive findings long before there was a tendency to stiffness of the neck in the cases in his service. Whenever it appeared the patient had been sick for some time. Even when the cerebrospinal fluid is found sterile, the petechiae in the skin suggested the correct diagnosis. Even more characteristic are lead colored spots between the petechiae or alone. These in his experience always heralded meningococcus infection even when there were no signs of meningitis or the spinal fluid was sterile. They are too large for hemorrhagic petechiae. The meningococcus was found in the blood in one case with sterile spinal puncture fluid. The trouble begins with sepsis, and only later does the infection settle on the meninges. He does not hesitate to start serotherapy at once when a man evidently acutely sick develops these lead blue spots even although the lumbar puncture fluid is still sterile. In treatment he draws from 30 to 50 c.c. of spinal fluid and injects 20 c.c. of the antiserum the first three or four days. In one case he repeated the injection the same day. In case the turbid fluid does not flow freely, he makes the injection subcutaneously. Six of the men succumbed. In two of them pus was found in the right frontal sinus besides the purulent meningitis.

114. **Meningococcus Meningitis.**—The ages were 2 years and 4 months in Schoondermark's two cases in children. Meningococci were found in the lumbar puncture fluid and the antiserum was pushed, seven intraspinal injections being given, about 6 or 8 c.c. at a time. No benefit was apparent for some days, but then the children recuperated and recovered completely with no sequelae.

118 *Scarlet Fever and Milk. A. Djørup.—p. 1645.

116. **Colon Bacillus Otitis.**—Lund states that at the clinic for ear and throat disease at Copenhagen during the last ten years 569 simple mastoid operations were done, and in 372 with the middle ear operation beside. Bacteriologic examination in 306 cases showed the colon bacillus in 12, dubious in 5 additional cases. In 2 of the 12 cases there was merely mastoid suppuration, but in the 10 others there were serious complications, mostly intracranial and multiple. The 7 cases with thrombophlebitis showed infarcts in the lung in 3 and gangrene in 2, while there was one instance each of metastatic pyothorax, pleural empyema, pneumonia, pericarditis and peritonitis. There was a mastoid abscess only in 5 of the total 12 cases, but an epidural abscess was found in 9. Diffuse purulent meningitis was encountered in 5 of the 12 cases and colon bacilli were found in the fluid in one case on lumbar puncture. The colon bacillus infection seemed to occur only as a sequence to old chronic otitis media. The mortality in the 12 cases was about 60 per cent.

118. **Scarlet Fever and Milk.**—Djørup analyzes a recent epidemic of scarlet fever at Copenhagen. One day reports of cases began to come in from all over the town, and the same day it was established that all these families took milk from one milk company. Three of the employees developed scarlet fever that same day. A fourth employee had been taken to the hospital five days before, and now had scarlet fever. This seemed to be the human source, and as he had not been near the milk distributing plant for so many days, there seemed no necessity for closing it. The children's milk was ordered to be pasteurized. But the next day there were forty-five new admissions for scarlet fever, and in five days there were 236 cases notified, and 200 of the patients had taken milk from this one milk company. It was also ascertained that the supposed "human source" had entered the hospital for treatment of a burn, and that the scarlet fever had not developed until the day that the epidemic had "exploded."

The human source was finally found in one of the two dairy farms supplying the company, an immigrant girl who did part of the milking having been sick with scarlet fever for ten days when the epidemic exploded. She had kept at work throughout. This dairy farm had been telephoned to at the first. If the question asked had been "Is there any one at the farm with hives or other eruptions?" the answer would have been in the affirmative. The scarlet fever had not been recognized, no physician having been called in. The milk from this dairy farm was returned and every one on the place was examined by a physician at night and before being allowed to go to work in the morning. In the course of two and a half weeks four persons on the farm were found to have sore throat and they were at once excluded; two of them proved to be coming down with scarlet fever. The epidemic died out the fifth day after milk from this dairy farm had been excluded from the market, the extinction of the epidemic occurring almost as abruptly as the onset. The milk distributing company paid the expense of the investigation. Diarrhea was the first sign of trouble in many of those affected but nephritis was rare. The glands in the neck became enlarged in some, and several children died.

EXSTROPHY OF THE BLADDER AND ITS TREATMENT *

CHARLES H. MAYO, M.D.
ROCHESTER, MINN.

Exstrophy of the bladder is a rare congenital malformation; it is reported by Neudörfer[1] as occurring once in 50,000 births. The anomaly is probably occasioned by variations of the salts in the amniotic fluid surrounding the embryo. It is one of the most serious of malformations, as approximately one half of those suffering from it die during the first ten years of life, and the great majority are dead before they are 40. The condition is very distressing from the tenderness and the difficulty of protecting the protruding bladder, the constantly dribbling urine requiring much absorptive dressing or an equally foul smelling receptacle which leads such persons to shun society. Associated defects are epispadias in the male, an absence of the anterior pubic bone in all cases, and an apparent absence of the umbilicus, which becomes the upper margin of the mucocutaneous juncture, the urachus being absent. In the case of a child of 5 in whom exstrophy was the result of assault, it was asserted that the pubic bone later disappeared, causing the condition to resemble congenital exstrophy.[2] The lack of the pubic arch makes the pelvis apparently wider, and the sacro-iliac joints become fixed early. In the female, procreation is possible. Winslow[3] has reported the condition in a woman who had given birth to four children (Fig. 1).

The various measures for improving the condition are plastic skin covering or closure of the bladder mucosa. This method was highly developed by Roux[4] in 1852 and has been variously modified since by Thiersch,[5] Nélaton,[6] Wood[7] and others. The great defect by the plastic closure methods came from the necessity of using hair-growing skin, which later accumulates lime deposit and adds to the foulness of the uncontrolled bladder. Passavant[8] aided the closure by compressing the half formed pubic arches, and Koch,[9] König[10] and others made subcutaneous section of the bony arches. Trendelenburg[11] added to this method the partial separation of the sacro-iliac joint to more nearly approximate the pubic arches over the bladder. The septic uncontrolled pouches formed by these operations made it possible to wear some sort of drainage apparatus in which a portion of the urine could be accumulated, but the danger of diseased kidneys from ascending infection was actually increased. Additional methods of treatment were devised by Subbotin[12] and Lerda,[13] who, before closing the bladder, tunneled a space between the sphincter ani and the rectal mucosa and drew through it a folded strip of bladder wall as a tube, the anal sphincter closing the new urethra as well as the anus. The operative mortality in these cases was 25 per cent., and the bladder still remained a septic sac.

Another method for the relief of the deformity was to construct other closed cavities to serve as a bladder. Gersuny[14] separated a loop of bowel, and after establishing the continuity of the alimentary canal, brought the lower end of the loop through a tunnel opening within the anal sphincter as in the Subbotin method, the ureters being inserted into the upper end of the loop, which also developed a septic tank. The operation of Makkas[15] developed a bladder from the cecum. The ileum was divided at the ileocecal valve, which was closed on the cecal side, the ascending colon divided and both ends closed, and the ileum joined end to side in the upper segment of the ascending colon. The appendix was brought through the abdominal wall as an appendicostomy, the new bladder being emptied at regular intervals by a catheter passed through the appendix. This operation was performed in 1910. I saw his patient two years afterward. At that time the ureters were enormously dilated from the cecum to the kidneys, and the new bladder was septic. The cloaca of birds was looked on as a solution of the problem. The ureters were joined to the sigmoid or rectosigmoid, and the rectum was utilized as both a fecal and a urinary receptacle. The high mortality of this method showed a necessity for improvement in technic, but the control was good. To

avoid ascending infection and dilatation of the ureters the sigmoid was divided, the proximal sigmoid joined end to side into the rectosigmoid, and the ureters inserted into the upper end of the distal sigmoid. While the feces did not flow over the ends of the ureters directly, the gas, fluids and bacteria could not be prevented from causing infection, and there was but little improvement in the mortality. Other methods were to insert the right ureter into the appendix and the left into the sigmoid, but with these also there was ascending infection of the kidneys.

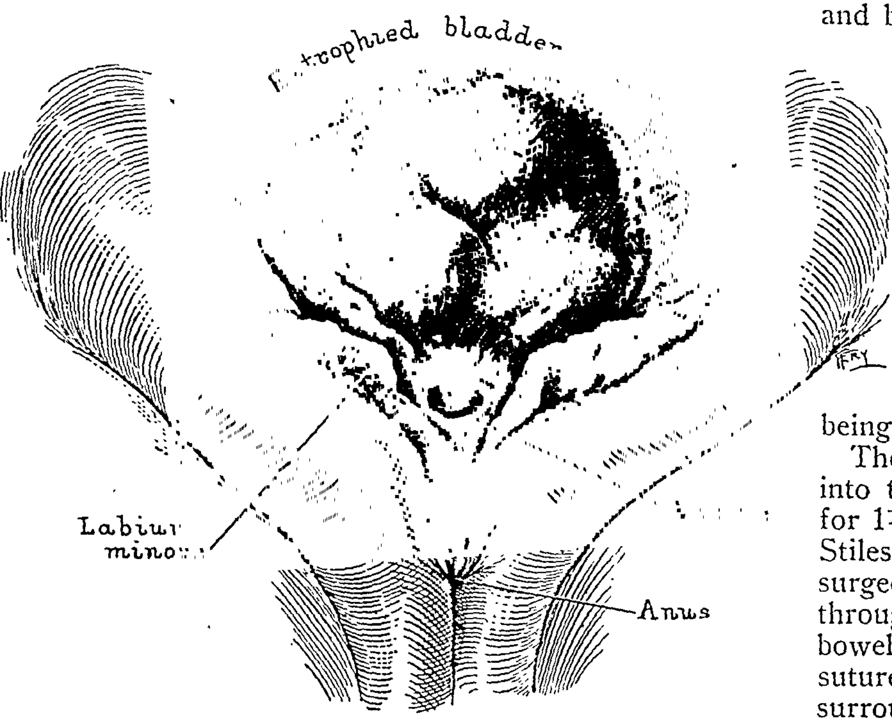

Fig. 1.—Exstrophy of bladder in the female; exposed mucosa with ureteral openings.

The next modification was to preserve the small openings of the ureters as they passed through the walls of the bladder, in the belief that this mechanism was Nature's safeguard against infection. The Maydl[16] operation, developed in 1892, removed the base of the bladder with the ureters attached and inserted the reversed segment into an incision in the anterior wall of the rectum. The operation is performed extraperitoneally and has been done transperitoneally. In the male it is not difficult, but in the female it is complicated. By this method Russian surgeons report a mortality of 32 per cent., Orlow[17] a mortality of 17 per cent. in sixty-one cases, and Drucbert[18] a mortality of 27 per cent. in eighty-one cases within fifteen days of the operation. We operated on three patients by this method, and two died. Moynihan[19] uses a larger area of the bladder in the Maydl operation, thus greatly increasing the rectal capacity. Sherman's[20] work with Peters' modification, based on the belief that the protection is in the small orifice of the ureter, was to dissect the ureter out of the bladder, retaining the mucus-covered ends intact, and to transplant them into the rectum.

It is true that Nature's method of emptying a duct is always by indirection; thus the salivary ducts, the common duct of the liver and the ureters pass through the muscularis and continue for a distance between the mucous membrane and the firmer outer wall of the cavity. Pressure from within compresses the ducts, and blocks against dilatation and ascending infection. The fact seemingly was not recognized that the mechanical principle of the passage of the ureter through the wall of the bladder and its mucosa could not be retained after the loss of its innervation. The surgical principle of such duct entrances is recognized in the Witzel[21] operation of gastrostomy and enterostomy, in which leakage is prevented by the tunnel made by folding the wall of the stomach or bowel over the tube for 1¼ inches. The Stamm-Kader[22] method accomplishes the same thing by a series of purse strings, a funnel entrance being made into the viscus.

The secret of successfully anastomosing the ureter into the bowel is to tubularize the ureteral entrance for 1¼ inches. There are two methods of doing this. Stiles[23] followed the plan of the Russian and Polish surgeons of passing the ureter into the intestine through a small opening, and depressing it into the bowel, which is folded over it, the folds being held by suture; the mechanism then consists of the ureter surrounded by the whole thickness of the wall of the intestine—the Witzel method. Coffey's[24] modification was first developed for the treatment of obstruction of the common duct of the liver by uniting it with the duodenum, and has proved most efficient for ureteral transplantation. It does not narrow the lumen of the intestine, and is carried out as follows: The peritoneum and muscularis are incised longitudinally for from 1¼ to 1½ inches down to the mucous membrane but not through it. The incision is best made in the firmer longitudinal bands of the wall of the sigmoid.

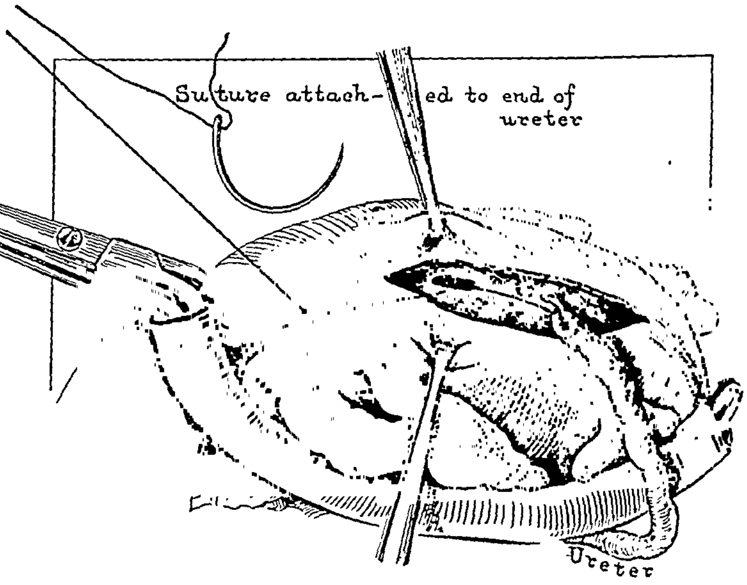

Fig. 2.—Ureter ready to be drawn through incision, into lumen of bowel.

The ureter is exposed by an incision in the peritoneum in the posterior pelvic wall, and is isolated to within

1 or 1½ inches of the bladder, where it is divided and the distal end ligated. From 2½ to 3 inches of the ureter are separated, the posterior peritoneal incision is closed by suture to the point where it emerges, the lower end of the ureter is split for one-fourth inch, a curved needle with chromic catgut is passed through the end, the catgut is tied, and the short end of the thread is cut.

The mucous membrane in the lower end of the incision in the wall of the intestine is now perforated into its lumen. In preparing for this and to prevent contamination of the wound, a large curved rubber-covered clamp is used to hold the bowel in position, and the union is made within the curve of the clamp. The curved needle on the catgut attached to the end of the ureter is passed into the lumen of the bowel through the small opening and out of the wall of the bowel one-half inch below it. Drawing the chromic catgut suture pulls the end of the ureter into the lumen of the bowel. The needle is then passed once through the peritoneum and muscularis in order that the catgut may be tied to hold the ureter fixed within the wall of the intestine. The sides of the incision in the outer wall of the bowel are closed over the ureter, the needle including its outer tissue in two or three sutures. A second row of peritoneal sutures is placed over this, extending down over the tied knot of the fixation suture which holds the ureter in place (Figs. 2 and 3). This gives the ureter a natural duct entrance. The slightest pressure from within closes the duct, but not sufficiently to prevent the delivery of urine by the automatic and intermittent waves of contraction occurring about six to eight times a minute during the period of activity.

The abdominal incision for the work is a low lateral pelvic incision, and is best made on the right side first. As the sigmoid naturally passes to the left, it can always be reached; while if the incision is made on the left side first, the slack bowel may have entirely disappeared from the attachments of the former operations. The intestine is held by a few sutures to the posterior peritoneum so as to cover the ureteral entrance. It is best to do but one side at the first operation, as the urine is absorbed from the large bowel like a Murphy drip. Tolerance is soon acquired, however, and the slight uremic mental apathy disappears in a week. The second ureter may be transplanted with no trouble in from one to two weeks after the first operation. A small tube may be kept in the rectum for the first few days unless it adds to the discomfort. Usually at once or at least within a few days the urine will be passed at moderately frequent intervals.

The right half of the colon is the absorbing side of the intestine. Little work is done by the lymphatics, nearly all absorption being by osmosis, and the fluids are taken by the portal circulation to the liver. It is not good judgment to use the right side of the colon for an anastomosis. Experimental work recently reported,[25] in which it was hoped that by utilizing a natural duct entrance into the intestine ascending infection could be avoided, showed that one ureter could be passed through the duct of Santorini, and the absorption of the urine from one kidney would not give marked symptoms, though when the second ureter was inserted the animals died from uremia. This was also shown in Connell's[26] experiments, in which the small intestine was used. Therefore we must keep to the large bowel and preferably to its lower end. Transplanting the ureters is advisable in the few cases in which extensive destruction of the base of the bladder and urethra have occurred following childbirth.

Children should be old enough to be able to attend to their own needs, that is, from 3½ to 5 years of age. In early life, also, there may be defects in the innervation of the rectum; and if prolapse of the rectum accompanies the exstrophy, this condition must be overcome by time, or by operation before the cloacal condition is instituted. After the age of 40 it is probable that ureteral anastomosis with the skin in the back is best from the standpoint of low mortality and future length of life. In this position receptacles can be readily adjusted for the collection of urine. The report of the cases mentioned below reveals the important fact that after operation these children were able to go to school and receive an education, which was impossible in their former state. The older ones are all working. One young woman has taken a three-year course in nurse's training, and a year ago passed through an attack of erysipelas without bad results.

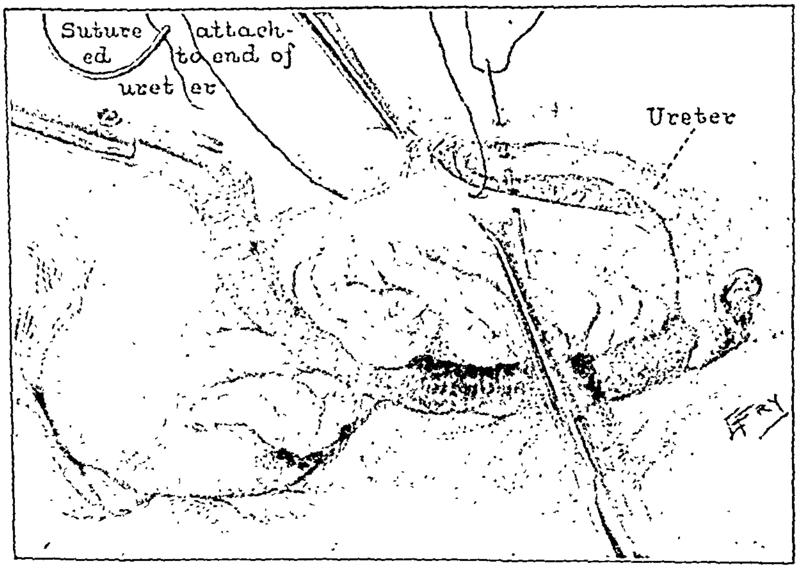

Fig. 3.—Infolded ureter in large bowel similar to gastrostomy.

Since 1896 we have seen thirty-seven patients with exstrophy of the bladder. Fifteen of these were not operated on at the time of their examination, some were too young to be operated on, and the others expected to return for operation. Six patients were operated on by the plastic method. One died six months later (traumatic exstrophy at childbirth; the child weighed 12½ pounds). The plastic operations did not afford control of the urine. Three patients were operated on by the Maydl-Moynihan method, and two died in the hospital, of uremia. Thirteen were successfully operated on by the transplantation method, with one operative death. One died from pneumonia a few weeks after leaving the clinic. One died three years after operation from pulmonary tuberculosis, and one three years after operation from typhoid fever.

NEUROTIZATION OF PARALYZED MUSCLE BY MUSCLE GRAFTING

A LABORATORY AND CLINICAL STUDY *

JOHN JOSEPH NUTT, M.D.
NEW YORK

This study was undertaken for the purpose of determining whether function could be returned to a muscle paralyzed by poliomyelitis, through the growth into it of nerves from a neighboring sound muscle. This neurotization I proposed to accomplish, not by implanting a sound nerve directly into the body of the paralyzed muscle, but by splitting the sheaths of both the normal and the paralyzed muscles, scarifying the fibers so as to remove all obstruction offered by the sarcolemma to the growth and extension of nerves, and then suturing the open surfaces of the two muscles together.

It has been my experience in one or two instances that after the transplantation of the biceps to do the work of the paralyzed quadriceps, there has followed some return of power to the paralyzed muscle. This may have been the result of unintentional muscle grafting.

In a personal communication, Sayre has informed me that in 1898, after an operation for paralysis in which all the anterior muscles of the foot were affected, with the exception of the extensor longus pollicis, he had a result which could not have been due entirely to the operation unless he unknowingly did more than he had planned. He performed the Parrish operation[1]: a fusion of the tendons of the tibialis anticus and the extensor longus pollicis, operating above the annular ligament, and, through the incision, he had made a careful examination of all the other muscles. Much to his surprise, power returned to the extensor communis digitorum. It is possible that he destroyed the intermuscular septum and the sarcolemma sufficiently to permit a muscle grafting.

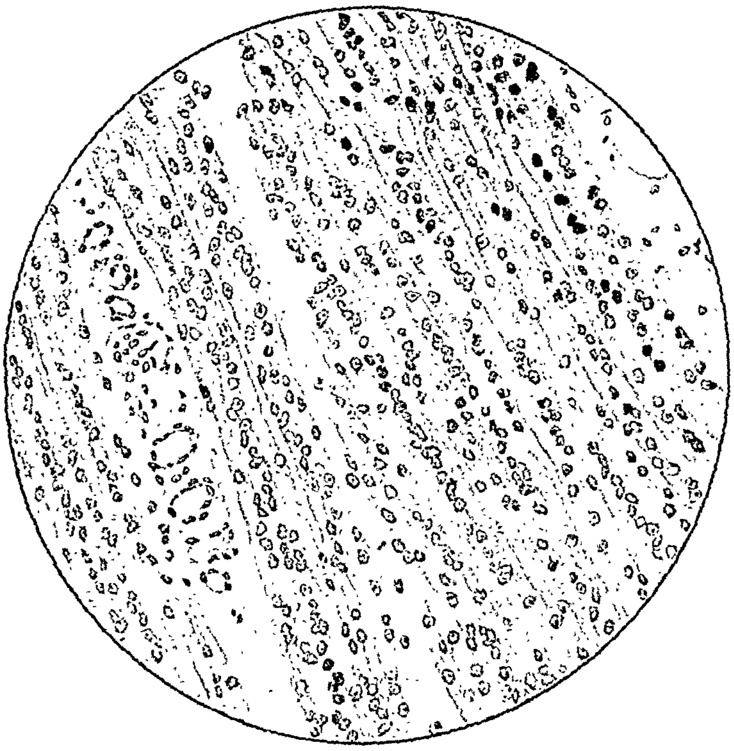

Fig. 1.—Muscle paralyzed by poliomyelitis. Fibers shrunken as in atrophy from disuse.

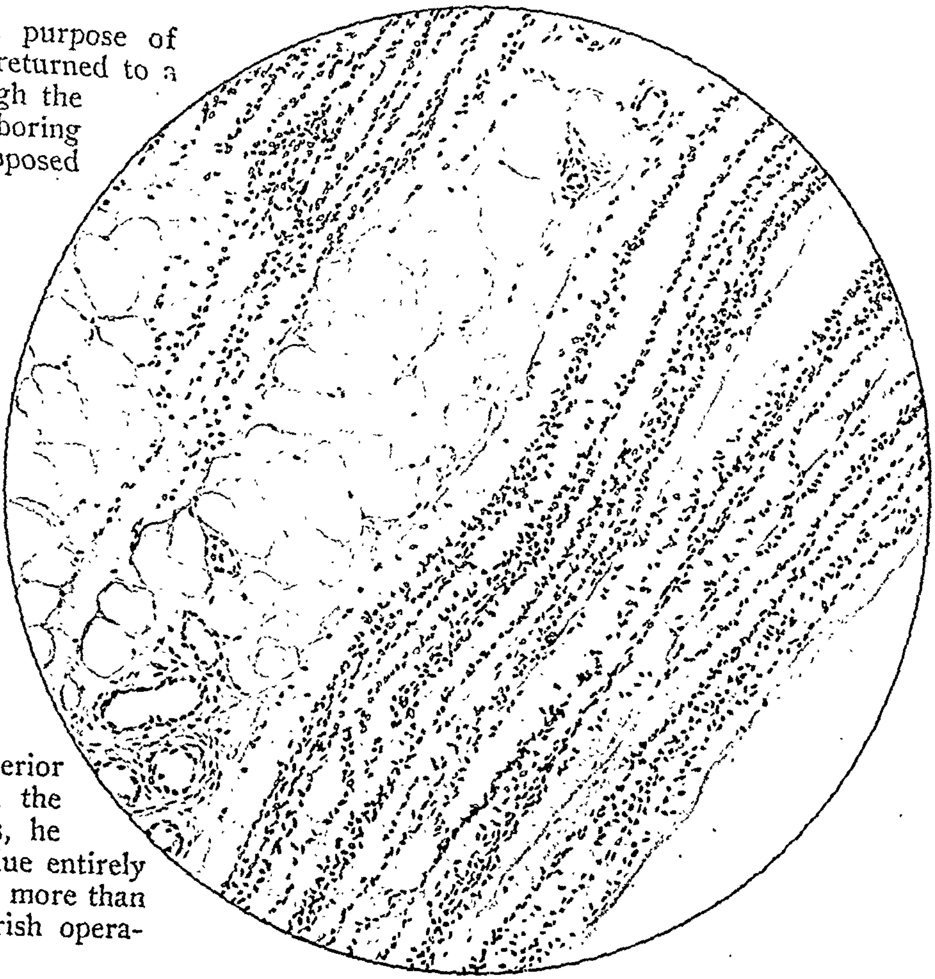

Fig. 2.—Muscle paralyzed by poliomyelitis. The great number of nuclei show that an unsuccessful attempt at regeneration has been made. Striations are absent; fibers are shrunken, and fat is deposited between them.

In June, 1905, Gersuny[2] grafted the deltoid to the trapezius for a shoulder paralysis. The patient was a young man and the cause of the condition is in doubt. After three months there was a slight return of movement. During the following months, improvement continued until in November the arm could be used normally except for the fact that it was still weaker than the other arm.

In February, 1907, von Hacker[3] operated for paralysis of the shoulder which followed an operation for tuberculous glands of the neck. His muscle grafting was at least partially successful, as the patient could lift the arm to the horizontal five months later.

The neurotization of paralyzed muscle by nerve implantation has been done by several surgeons. Heineke[4] has reported successful experiments, and Erlacher[5] has not only reported successes but claimed that hyperneurotization is possible. Steindler[6] of Iowa City has been successful in neurotizing paralyzed muscle by the implantation of sound nerves, but he does not believe it possible to hyperneurotize a muscle.

[6] Steindler: Am. Jour. Orthop. Surg., 1914-1915, **13**, 33; ibid., 1916, **14**, *707*.

Elsberg[7] has determined a remarkable fact, namely, that if an artificially paralyzed muscle is implanted with its original nerve and also another motor nerve, reestablishment of function takes place through the original nerve and not through the foreign nerve. On the other hand, if the original nerve were not implanted, the foreign nerve would take up the work. He agrees with Steindler that hyperneurotization is impossible. He also found that eight weeks of paralysis produced the characteristics of atrophy, and that eight weeks after nerve implantation, normal appearance was regained and good contraction established. He reports several successful neurotizations, in which he transplanted a portion of the sound muscle with the nerve. Gerster and Cunningham[8] report successes with nerve implantation.

By experimenting on dogs, I have sought to inform myself regarding paralytic changes in muscles and also the changes which take place as a result of muscle grafting. This part of the work has been carried on in the Department of Experimental Surgery of the New York University and Bellevue Hospital Medical College. The histologic studies have been made by Dr. Alexander Fraser of the pathologic department.

The anterior tibial and the sciatic nerves were selected for section in the work on dogs. After an interval following the former operation and varying from two to six weeks, the paralyzed tibialis anticus muscle was grafted to the normal peroneus. After resection of a portion of the sciatic, the vastus externus was grafted to the paralyzed biceps.

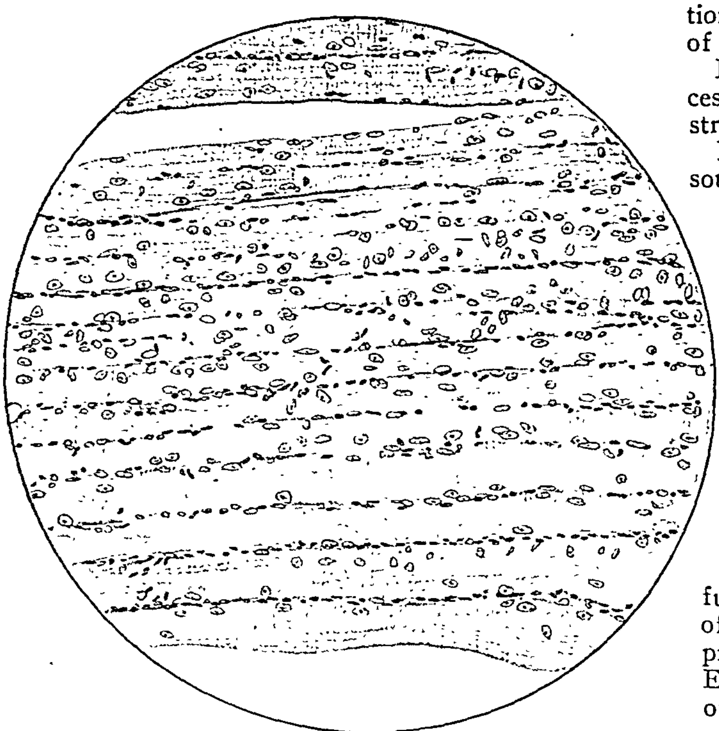

Fig. 3.—A successful attempt at regeneration in a dog. Fibers are compact, and striations may be seen.

Figure 1 shows atrophy in a specimen taken from a case of poliomyelitis. The same characteristics would be present in an atrophy from disuse. If there is absolute separation of a muscle from all nerve supply, a condition seldom obtained and perhaps impossible to obtain except in the case of the external rectus of the eye, the fibers undergo fatty degeneration. In atrophy from poliomyelitis, however, the muscle fibers are shrunken, and the nuclei increased, and there is no evidence of fatty degeneration.

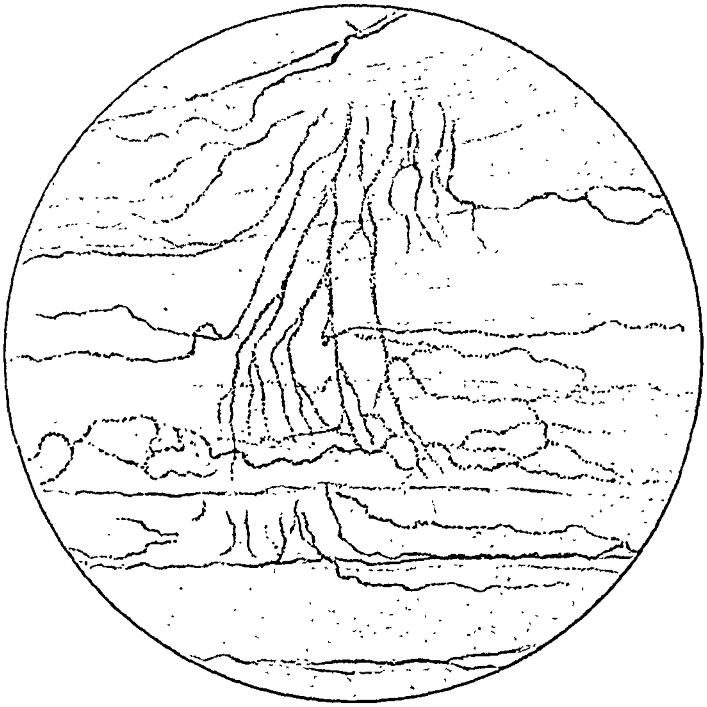

Fig. 4.—Nerves growing from paralyzed muscle above into paralyzed muscle below. Their dotted appearance and the straightness of their course are characteristic of new nerve growth.

Figure 2 shows an unsuccessful attempt at regeneration. The great number of nuclei testify to the activity of the endeavor, but there are no striations of fibers.

Figure 3, obtained from a dog, illustrates the successful attempt at regeneration. Note the nuclei, the striations and the compactness of the fibers.

Figures 4 and 5 show the growth of nerves from the sound muscle into the paralyzed muscle.

Figure 6 shows an end plate which in all probability is from the new nerve growth following the grafting operation.

The last three specimens were taken from a dog six weeks after the grafting operation and nine weeks after the artificial paralysis.

The operations on patients have been performed at the State Hospital for the Care of Crippled and Deformed Children and at the College Clinic. Specimens were taken and examined by Fraser from all of the clinical cases except six. The extent of atrophy was found not to be commensurate with the time since the attack, but to depend on the completeness of the paralysis. Loss of function may be complete in two muscles, and yet one of them may have sufficient nerve supply preserved to prevent the complete atrophy experienced by the other. Electricity has not helped me in estimating the extent of the paralysis, that is, the extent of the nerve supply remaining after the easily demonstrated loss of function. The discovery of some method of ascertaining the exact condition of the muscle before operation is greatly to be desired.

It is quite obvious that any attempt to regenerate a muscle which has lost all trace of muscle fiber would be futile. This was true in several of the patients operated on. They are all reported as cases of muscle

---

8. Gerster and Cunningham: Med. Rec., New York, 1917, 92, 23.

grafting, since I finished the operations as nearly as possible as originally planned.

The operation is done as follows: An incision is made to bring into the field the bellies of the two muscles. Both are split lengthwise. The deeper edges of the two opened surfaces are sewed together with chromicized catgut. A few interrupted sutures are so placed as to approximate the central parts of the two freshened surfaces, and then the upper edges of the cuts are sewed together. The skin wound is then closed.

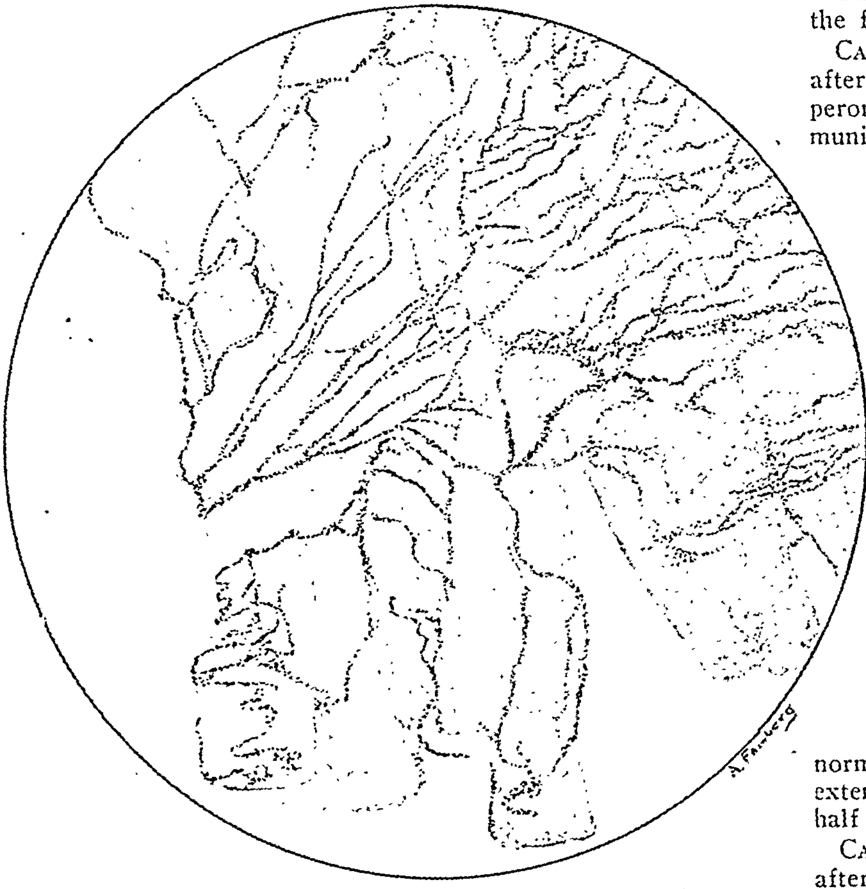

Fig. 5.—Another section showing new nerve growth.

It will be seen that even if nothing is gained by such an operation, nothing is lost. No function is sacrificed, as is the case in such operations as muscle transplantation, tendon fixation and nerve implantation. The objection to early operation, which is so valid in all other procedures, does not hold good for this operation.

Sixteen cases, all I had done up to August, are here reported in the order of operation. In four of them, two paralyzed muscles each were operated on, making a total of twenty muscle graftings. Seven were complete failures, although one of these was operated on as recently as July 27 and may yet prove to be of some value. Six patients show a slight return of power, which, however, is by no means sufficient to be of functional use. This slight power, as we know from similar results in muscle transplantation, may add to the strength of the joint and thus be of some benefit. Four cases have given fair results and three good results. The last seven cases give us the courage to report our work at this time, although we fully realize that much more will have to be done in both the laboratory and the clinic before the operation should be either unconditionally accepted or discarded.

REPORT OF CASES

Case 1.—C. B., aged 15, was operated on, Dec. 15, 1915, after an attack occurring nine years before. The normal gastrocnemius was grafted to the paralyzed peroneus longus. There was no return of power.

Case 2.—J. D., aged 18, was operated on, Dec. 11, 1916, after an attack in early childhood. The normal soleus was grafted to the paralyzed peronei.

The result was good, as the peronei can now contract and the foot can be abducted.

Case 3.—G. B., aged 14, was operated on, Feb. 12, 1917, after an attack occurring five years previously. The normal peroneus longus was grafted to the paralyzed extensor communis digitorum.

The result was good, as it was estimated that there was a return of fully half the muscle's normal power. A second operation was performed, March 18, when the normal biceps was grafted to the paralyzed vastus externus.

The result was slight, as the patella can now be moved upward and outward in attempts to extend the leg, and, with the opposition of gravity removed, extension is possible.

Case 4.—E. N., aged 9, was operated on, Feb. 12, 1917, after an attack occurring at the age of 3. The normal tibialis anticus was grafted to the paralyzed extensor longus pollicis. There was no return of power.

Case 5.—B. S., aged 13, was operated on, Feb. 23, 1917, after an attack occurring seven years previously. The normal peroneus longus was grafted to the paralyzed extensor communis digitorum. There was a slight return of power.

Case 6.—J. M., aged 10, was operated on, Feb. 23, 1917, after an attack occurring four years before. The normal extensor longus pollicis was grafted to the paralyzed extensor communis digitorum. The result was good, as fully half the normal power was restored.

Case 7.—H. B., aged 9, was operated on, March 7, 1917, after an attack occurring six years previously. The normal extensor longus pollicis was grafted to the paralyzed tibialis anticus and the normal soleus to the paralyzed tibialis posticus. There was no return of power.

Case 8.—M. M., aged 4, was operated on, March 12, 1917, after an attack occurring ten months previously. The normal biceps was grafted to the paralyzed vastus externus. A fair result was obtained with the opposition of gravity removed; the patient can extend his leg.

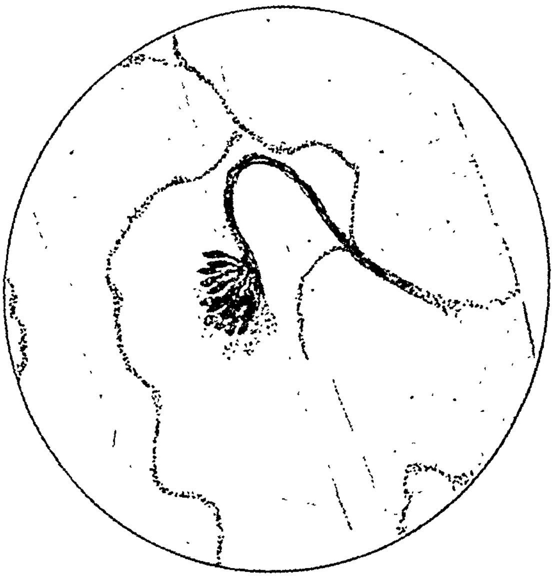

Fig. 6.—An end plate from a muscle-grafting specimen, in all probability from the new nerve growth.

Case 9.—J. C., aged 2, was operated on, March 12, 1917, after an attack occurring one year previously. The normal tibialis anticus was grafted to the paralyzed extensor communis digitorum, and the normal flexor longus digitorum to the paralyzed soleus. The result was a fair return to the extensor communis digitorum, and a very slight return to the soleus.

Case 10.—M. H., aged 6, was operated on, March 15, 1917, after an attack occurring one year previously. The normal extensor longus pollicis was grafted to the paralyzed tibialis anticus. The result was a slight return of power.

Case 11.—H. McC., aged 9, was operated on, March 23, 1917, after an attack occurring one year previously. The normal peroneus longus was grafted to the paralyzed extensor longus digitorum. There was no return of power.

Case 12.—R. L., aged 9, was operated on, April 1, 1917, after an attack occurring seven years previously. The normal biceps was grafted to the paralyzed vastus externus.

There was a slight return of power, so that the patient can now extend his leg, with the opposition of gravity removed.

Case 13.—E. H., aged 11, was operated on, May 3, 1917, after an attack occurring at the age of 2. The normal peroneus was grafted to the paralyzed soleus, and the normal extensor longus pollicis to the paralyzed tibialis anticus.

Fair results were obtained in the tibialis anticus and none in the soleus.

Case 14.—M. E., aged 12, was operated on, May 7, 1917, after an attack occurring in early childhood. The normal peroneus longus was grafted to the paralyzed soleus. The result was fair, as the muscle now contracts with perhaps half its normal strength.

Case 15.—W. L., aged 12, was operated on, July 27, 1917, after an attack occurring five years previously. The normal extensor longus pollicis was grafted to the paralyzed tibialis anticus. The result was a slight return of power.

Case 16.—R. S., aged 5, was operated on, July 27, 1917, the time of the attack being unknown. The normal extensor longus pollicis was grafted to the paralyzed tibialis anticus. There was no result.

Death Rate and Invalidity in Australia.—The report of the Committee Concerning the Causes of Death and Invalidity in the Commonwealth of Australia, issued in 1917, contains some interesting figures on community health in that country. In 1914 the general death rate for males was 11.7, for females, 9.3 per thousand. In our own registration area for the same period, the rates were 14.5 and 12.7 per thousand. One of the reasons assigned for the lower rate in Australia is the fact that the country is peopled with young men and women. A standardization for age would increase the rates.

The infant mortality rate in 1913 was 72.2 per thousand infants born alive. The lowest rate ever recorded in Australia was 68.5 in 1911. New Zealand had a rate of 51.4 in 1914. The rate in the United States, in our most progressive cities, when it does not exceed 100 is considered very favorable. The birth rate in Australia in 1914 was twenty-eight per thousand as against forty-four per thousand in New South Wales in 1864 and thirty-eight in Victoria in 1870. This shows a decrease in the birth rate, as in European countries and the United States.

THE USE OF RELAXATION INCISIONS IN DEALING WITH EXTENSIVE UNSTABLE SCARS

JOHN STAIGE DAVIS, M.D.
Fellow of the American College of Surgeons.
BALTIMORE

The treatment of tightly stretched unstable scars that frequently break down has long been a source of worry to the surgeon, and of distress to the patient.

This type of scar usually follows extensive deep burns, or loss of tissue by trauma when the wound has been allowed to heal by the slow process of cicatrization, without the aid of skin grafting or of plastic operation.

The original wounds are always large and usually involve the entire circumference of a part, such as the leg or thigh, or occasionally the calvarium. In other words, the scar surrounds and compresses the part.

Some of the scars are bluish red with fine superficial vessels, while others are pale and seem to have little or no blood supply. Frequently there are superficial ulcers of varying size scattered over the surface. The scars are as unstable as wet tissue paper, and the slightest injury will start an ulcer that will require weeks to heal.

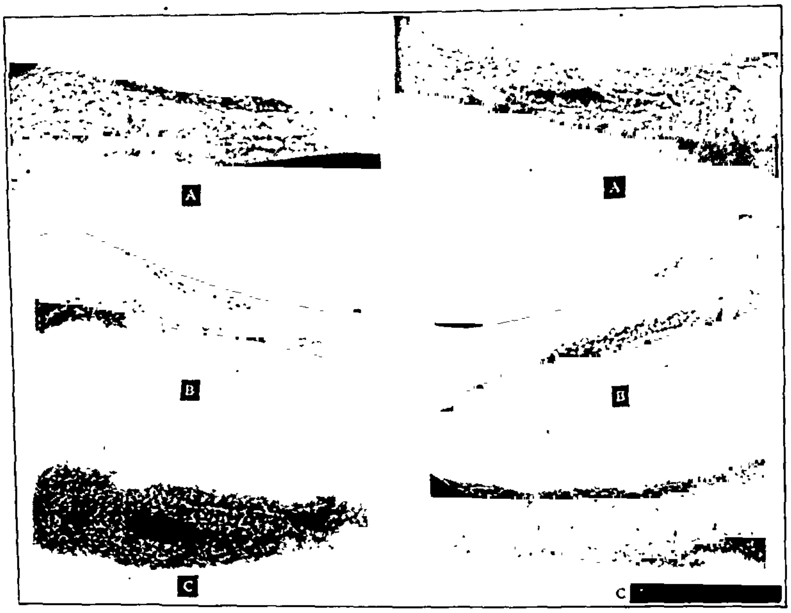

Fig. 1.—Scar involving the entire circumference of the leg. The patient had been bedridden for twenty-five months following a third degree burn. After the superficial ulcers were healed, three relaxation incisions were made under Schleich's infiltration anesthesia down to the deep fascia. The tissue was unfavorable for immediate grafting; hence granulation tissue was allowed to form in the wounds. *A*, four days after the incisions were made. The atrophy of the leg should be noted. The widths at the centers of the incisions were 3, 2¼ and 1¾ inches. These defects were grafted with small deep grafts on the fifth day after the operation. *B*, the individual grafts and the firm, healthy appearance of the scar between the grafted areas, two months after grafting. *C*, six months after grafting. The width of the grafted areas should be noted. The depressions have filled up to the normal skin level. The leg has developed, and the patient walks without difficulty, and has again taken up his work.

There is little resistance to trauma or infection, and an area that is healed may, without any apparent cause in a very short time, break down entirely, or multiple ulcers may develop.

A number of these patients have come under my care, and for a long time they gave me much trouble. After I had used many methods with little success, it occurred to me to try relaxation incisions, and to graft the defects thus made.

TECHNIC

It is preferable that the area be entirely healed before the incisions are made, but in some instances when the healing of the superficial ulcers has been extremely sluggish I have not waited for complete healing, but have operated as soon as the granulations have been brought into healthy condition. In preparation for operation in the unhealed cases, after the granulations are healthy, the part is put up in a dressing kept wet with physiologic sodium chlorid solution for twenty-four hours. The granulations are then painted with tincture of iodin, and the surrounding scar is cleaned with ether and alcohol.

Often the relaxation incisions can be made after infiltration with a local anesthetic, such as Schleich's solution, or 0.5 per cent. novocain. In other instances a general anesthetic is advisable, especially if large immediate Thiersch grafts are to be used to cover the defect.

On an arm or a leg (Fig. 1) long incisions should be made, parallel to the length of the part, down to the deep fascia or down to healthy tissue, if the destruction has been deeper than the fascia. Three relaxation incisions are usually sufficient for a limb, and they result in gaping wounds.

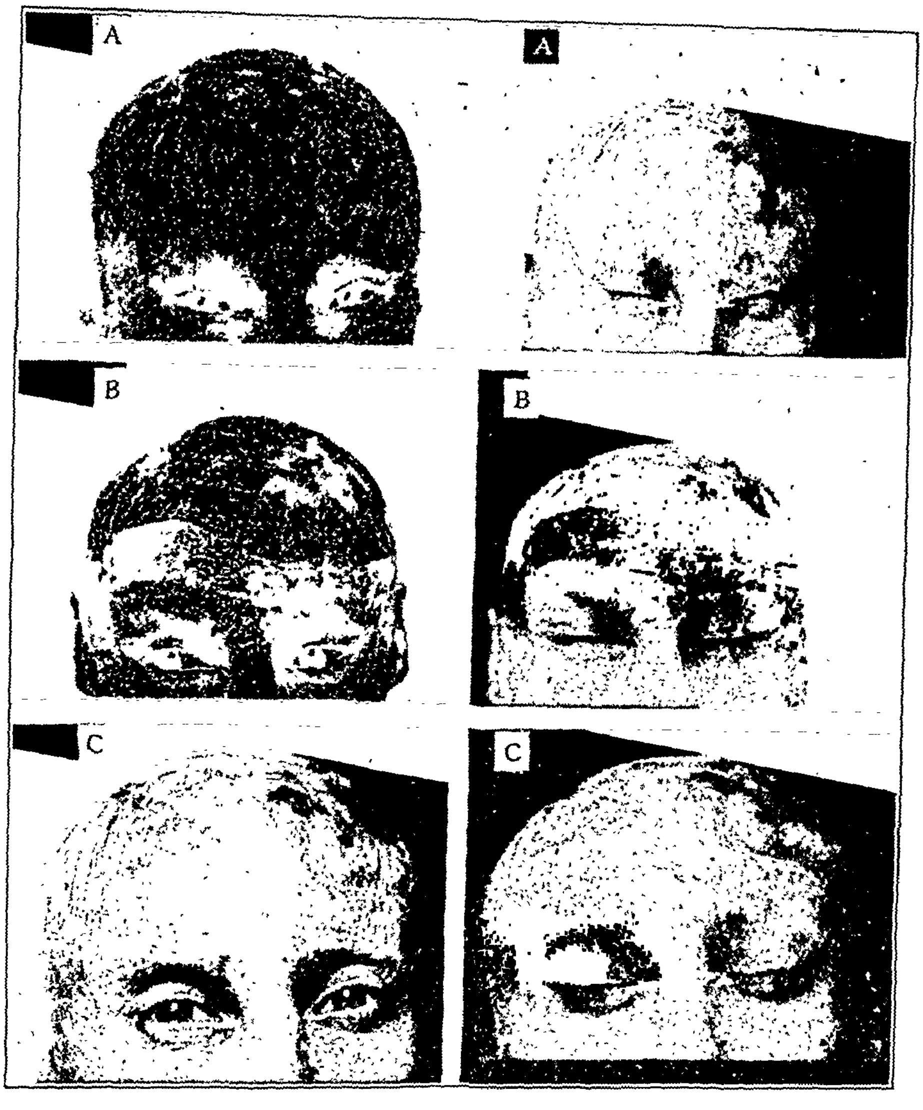

Fig. 2.—A tightly stretched adherent scar covering the entire cranium, the result of spontaneous healing following complete scalping. There were numerous superficial ulcerations. After ten days' treatment, and before complete healing of the ulcers, the relaxation incision was made. On account of the adherence of the scar to the skull, undercutting was necessary. A defect from 1⅓ to 2 inches wide was made across the forehead, from temporal region to temporal region. General anesthesia was necessary in this case, and the defect was grafted immediately with a single Thiersch graft from the thigh. *A*, before operation, five years after the accident. The face has the typical Mongolian expression caused by the pull of the scar tissue. The superficial ulcers should also be noted. *B*, two weeks after grafting. The graft has taken completely, and the ulcers are healed. Note the disappearance of the Mongolian expression. *C*, five months after grafting. The tension on the eyelids has been permanently relieved, and the condition of the scar on the vertex is much improved.

COMMENT

The immediate spread of each relaxation incision varies with the tightness of the scar. In some instances, it is as much as from 2½ to 3 inches at the center of the incision. The spread of the first incision is, of course, the widest.

After the tension is relieved, the appearance of the scar tissue between the incisions soon changes, and instead of the thin, glossy, mottled look, the tissue seems to thicken and to acquire greater stability. This improvement is much more marked after a few days.

When the scar is stretched over a broad expanse of bone, such as the skull (Fig. 2), as many horizontal incisions as may be necessary should be made down to the periosteum. The spread of relaxation incisions over bone is not so marked as over soft parts, and some undercutting may have to be done.

In these cases the beneficial effect is more marked after a week or two, but in the end the result is very satisfactory.

In some cases of very long standing the tissue, exposed by relaxation incisions, has atrophied from pressure and lack of use, and has such a poor blood supply that immediate grafting is unwise. In these cases it is advisable to wait for several days until the wounds are lined with granulation tissue, and then to apply the grafts.

In other instances, immediate grafting is justified; but this point must be determined at the time of the operation.

It is extraordinary to note the rapidity of healing of the superficial ulcers after the relaxation incisions are made.

I have used only small deep grafts and Thiersch grafts on the defects caused by the relaxation incisions. These grafts so far have been entirely satisfactory; however, there is no reason why grafts of whole thickness skin should not be used in cases in which this type of graft may be necessary.

There has been no recurrence of superficial ulceration in any case when the tension has been completely relieved by the method previously described.

CONCLUSIONS

By the use of relaxation incisions with immediate or subsequent skin grafting of the defects, large unstable scars can be strongly healed in a comparatively short time, and patients who have been incapacitated for many months can resume their usual occupations.

I have used this method in a number of cases, with uniform success, and feel that it is a rational procedure and well worth trying.

1200 Cathedral St.

Exportation of Condensed Milk.—In order to discourage the operations of food speculators who have been purchasing for export from the retail stores the brands of condensed milk which the manufacturers have set apart for the American public, the War Trade Board, at the request of the *Food Administration*, has announced the following regulation to govern the exportation of condensed milk: "No licenses shall be granted for the export of condensed, canned, powdered or other forms of preserved milk unless there shall have been filed with the Bureau of Exports a certificate of the manufacturer stating that such milk has been sold directly to the exporter and for export purposes, or unless compliance shall be had with such other regulations as may be determined by the Food Administration." According to *Commerce Reports* speculation in food products has created a false condition of the market.

PROPHYLAXIS IN CEREBROSPINAL SYPHILIS *

B. C. CORBUS, M.D.
CHICAGO

Of the treatment of general paresis, Ogilvie[1] has said:

> The real problem is to recognize invasion of the central nervous system before even the interstitial tissue or the meninges are involved to any destructive extent. It is the consistent opinion of authorities generally that these parts are invaded prior to this period. If neurologic involvement is detected at this stage, we have adequate means of controlling it, and if these are judiciously employed, general paresis will, in not far distant years, become a comparatively rare picture in medicine.

We may add, not only general paresis but any form of cerebrospinal involvement.

There is no form of the later manifestations of syphilis so heartrending to the patient and his family and so discouraging to the clinician as the involvement of the cerebrospinal system. Occurring most frequently many years after the primary infection, this class of cases presents a pitiful picture, for once the nerve tissue of the patient has been destroyed, all hope of regeneration is lost. It is true that the condition may be arrested, but most cases levy an economic toll of loss on both the state and the family.

In 1914,[2] I called attention to the value of cerebrospinal fluid examinations in so-called "cured" syphilis in patients treated by the biologic method, that is to say, by a Wassermann examination of the blood. This report showed that many patients having a negative blood Wassermann reaction for from eighteen months to two years without treatment had subarachnoid involvement. It was recommended that lumbar puncture, with spinal fluid examinations, be demanded in all cases of syphilis, no matter what the stage of the disease, as a control on future complications of the nervous system.

Since that time, as an additional diagnostic aid, 108 spinal punctures have been made on all patients, regardless of whether or not a definite history of syphilis was obtainable.

Each serum was examined for cell count after the method of Swift and Ellis, and for globulin by the method recommended by Ross Jones. The serologic examinations were made according to the original Wassermann technic, serial dilutions up to 1 and 2 c.c. being used. Recently the colloidal gold chlorid test has been employed in addition.

The percentage of cases showing involvement of the cerebrospinal system without clinical symptoms is as follows: primary, six cases with no involvement; secondary, twenty-seven cases, nine of which showed involvement, or 33⅓ per cent.; tertiary, five cases, two of which showed involvement, or 40 per cent., and latent, seventy cases, twenty-two of which showed involvement, or 31 per cent. Summing up these cases, we have, out of 108 cases of syphilis, thirty-three, or 30 per cent., which, although without definite clinical symptoms, showed early involvement of the nervous system. Surely this class of patients, if permitted to go untreated, will eventually show signs of degeneration as a result of their infection.

One eminent author[3] says that if dermatologists and genito-urinary surgeons were familiar with the early manifestations of nerve involvement they would uncover many cases of syphilis of the nervous system. This is undoubtedly true, and therapeutic attack begun early is now most promising of success. But what about the clinician who is unable to detect these early manifestations of cerebrospinal involvement?

Unfortunately, a large percentage of syphilitic patients are treated by members of the medical profession other than specialists. Often the diagnosis is delayed, and treatment is given with the object only of healing up lesions and securing a negative blood Wassermann reaction.

Today, syphilis exists everywhere and, if we read the statistics, we shall see that it bids fair to increase. The report of the United States Public Health Service, dated April 27, 1917, gives the following figures for syphilis and tuberculosis for the year 1916 for the city of New York, with an estimated population of 5,062,841: 20,128 cases of syphilis were reported, the rate being 3.592 per thousand, and 19,297 cases of tuberculosis were reported, with a rate of 3.444 per thousand. If we consider the difficulty of securing accurate data from the imperfect reporting of venereal diseases as compared with the highly efficient methods of reporting tuberculosis, the rate for venereal diseases is probably even greater.

What is going to happen to this vast army of syphilitics in the future?

Many observers have not the training or the skill to locate every minute nerve change; but a lumbar puncture, if made when the patient presents himself for examination, no matter how long previously he was treated and discharged, will reveal the true pathology as regards the cerebrospinal fluid. This is illustrated by Case 1.

CASE 1 (135).—A man came to my office one morning complaining of a slight urethral discharge. A slide was prepared, and he was instructed to urinate. This he said he could not do while I was in the room, so I went out. Returning in a few minutes, I noticed the lack of force of the urinary stream. I immediately asked him if he had ever had syphilis. "Oh yes," he said, "but I had a negative blood Wassermann." On further examination, the knee reflexes were found to be absent. This patient was strong and well, as far as he knew, and had never been sick in his life. The urinary symptoms were of such gradual development that they had attracted no attention. The spinal fluid examination revealed: cells, 122; globulin test, positive, and Wassermann reaction, positive.

With the discovery that active spirochetes can be recovered from the cerebrospinal fluid of patients suffering from cerebrospinal syphilis, ways and means of attacking the disease in the nervous system have been devised, and in some hands many of the methods have been fairly successful.

Most of the methods aim to introduce the specific agent or some modification thereof directly into the spinal canal. These methods at best, however, require special technic, and often after the most careful management, complications occur.

Having had considerable experience with the Swift-Ellis method and with that devised by Ravaut, I was reluctant to try these methods in early cases.

Few observers realize that to attempt intraspinal treatment in cases of secondary, tertiary and latent syphilis, and even in early tabes, is a mistake. In

1914 I[2] recommended that intensive intravenous injections should always be tried, especially in early cases, before intraspinal injections are resorted to. Sachs,[4] in a recent article, discusses the question of the therapeutic value of intraspinal injections. He reviews the situation impartially and comments on the failure of the intraspinal method.

Recently there has come under my observation a number of patients with slight symptoms referable to the nervous system in whom intraspinal treatment had been instituted in the form of mercurialized serum, with the result that complications more dangerous than the original symptoms arose.

Gilpin and Earley[5] believe that lumbar puncture, performed every week, or every two to three weeks, in order to reduce the pressure within the spinal column while intramuscular mercurial injections are being given, helps the mercury to pass into the cerebrospinal fluid.

Acting on this idea, I give intensive salvarsan injections combined with mercury rubbings in the following manner: Having satisfied myself by previous lumbar puncture as to whether or not definite or indefinite symptoms of subarachnoidal involvement are present, I give five doses of salvarsan, or some of the newer substitutes, in the course of two weeks. If the treatment is begun on Saturday, a second dose is given the next Wednesday, a third dose the following Saturday, a fourth dose the next Wednesday, and a fifth dose the following Saturday. The blood is examined at this time to see if arsenic is present. If so, it can be demonstrated by the Abelin test, which is as follows:

Reagents.—These are (1) resorcin, chemically pure; (2) hydrochloric acid, 20 per cent.; (3) sodium nitrite, 0.5 per cent.; (4) sodium hydroxid, 30 per cent.

Technic.—A 7.5 per cent. solution of resorcin is made up in the 30 per cent. sodium hydroxid. This can be kept as a stock solution. To 0.5 c.c. of cooled blood serum in a tube are added 8 drops of the hydrochloric acid and then 10 drops of the sodium nitrite solution, all of which are thoroughly mixed. In another tube is placed about 1 c.c. of the resorcin solution, to which is added, drop by drop, the serum treated with the acid and nitrite solution. In the presence of salvarsan or a changed amino derivative, a beautiful rose red contact ring appears most definitely in from one to two minutes. Normal serum gives a yellow ring.

One hour after the last injection, the patient is taken to the hospital, and lumbar drainage is performed. By this I mean the withdrawal of from 20 to 30 c.c., according to the pressure.

The great difficulty, as we all know, has been our inability to get salvarsan into the subarachnoid space in sufficient quantities to destroy the spirochetes.

It has been shown that salvarsan passes into milk secreted by the lacteal glands. Why, then, will it not pass through the choroid plexus if conditions are made ideal? The subarachnoid fluid is said to be secreted from the choroid plexus. If the fluid in the space is withdrawn in excess, the plexus must replace the fluid from the blood stream, which is saturated with salvarsan. This seems to me an ideal way to attack the infection. It compels the plexus to refill the canal from a blood stream saturated with salvarsan.

The patients are kept in bed for thirty-six hours with the foot of the bed elevated for twenty-four hours of that period.

In about ten days after this procedure, mercury rubbings are begun and continued for from three to four months. Then the salvarsan is again administered as previously described, lumbar drainage is performed, the fluid is examined, and the result is compared with the first examination.

It is my plan to continue the foregoing treatment twelve months after obtaining a negative spinal fluid, that is, through two series of salvarsan injections of five each and ten months of rubbings.

On alternate nights, during the treatment with mercury, the patient is rubbed on the chest and the back. Twice a week a hot bath is given, and the ointment all scrubbed off with soap and water. The patient is instructed to buy a tight-fitting undershirt, cut out the sleeves and wear this all the time under his nightshirt and also under his daily underwear, taking it off only when he bathes. This shirt rapidly fills with mercury and becomes a veritable pad, keeping the body continually in contact with the mercury.

Then, too, it is believed that by wearing this mercurialized shirt, the patient receives part of the mercury by inhalation. As he wears it continuously, night and day, some of the mercury is volatilized at body temperature, so that he has the additional advantage of mercury inhalation, with absorption through the skin. After a day or so, the odor, which at first may be very annoying, is hardly noticeable.

This shirt should be worn by the patient for at least six weeks. There is no objection to his taking a daily bath, but he is not permitted to wipe the mercury ointment from his chest and back. He should pat himself dry with a towel.

During the treatment with mercury, it is absolutely necessary to keep all fruit, fruit acids and buttermilk out of the patient's diet. If this precaution is strictly observed, with proper mouth hygiene, the gums will remain in a perfectly healthy condition. Equal parts of sodium bicarbonate and sodium chlorid make an excellent tooth-powder, which will also help to preserve the gums.

Occasionally, after six weeks of mercury rubbings, iodids are substituted for a month; then the mercury rubbings are resumed. I shall have no argument with those who prefer mercury injections to mercury rubbings. It is true that the rubbings are dirty, but in my hands this form of administration has been most effective.

REPORT OF CASES

In the following three cases, the intensive treatment was carried out. All showed stubborn infections, and a large amount of salvarsan was given, as will be seen from the records.

Case 3 (30).—H. D. H. manifested symptoms of secondary syphilis with spinal fluid involvement. The blood Wassermann reaction was positive. Treatment was begun, March 14, 1914. The patient received fourteen full doses of 0.6 gm. of salvarsan during a period of nine months, after which he showed a negative spinal fluid. Later he received two additional salvarsan injections. Since that time he has maintained a negative spinal fluid reaction without further treatment. Examinations were made, Nov. 10, 1914, Sept. 24, 1915, and May 18, 1917.

Case 3 (291).—C. G. manifested symptoms of secondary syphilis with spinal fluid involvement. The blood Wassermann reaction was positive. Treatment was begun, Feb. 3, 1913. This patient received twenty-nine doses of salvarsan during a period of three years and one month. He was one of the first treated by the intensive method, and mercury rubbings were used in conjunction with the salvarsan. He showed a negative spinal fluid reaction in January, 1916. One year later, January, 1917, without further treatment, he still had a negative reaction.

Case 4 (32).—G. K. L. manifested symptoms of secondary syphilis with spinal fluid involvement. The blood Wassermann reaction was positive. This case is most interesting, as the patient was over 50 years of age when he contracted the infection, and the diagnosis was delayed until he was in the full secondary stage. Treatment was begun, March 29, 1912. During a period of two years and seven months, he received twenty-two injections of salvarsan, together with the mercury rubbings. A negative spinal fluid test was obtained, Oct. 9, 1914. He maintained a negative serum reaction until almost one year later, Aug. 10, 1915. It is now three years since he has taken any treatment, and he writes me that he is in the best of health.

In the following three cases, spinal drainage was added to the intensive form of treatment.

Case 5 (135).—E. A. presented evidence of tabes with spinal fluid involvement. He was not aware of the spinal fluid involvement. He was feeling perfectly well. Treatment was begun, June 28, 1915. Spinal fluid examination revealed 122 cells per cubic millimeter, globulin test positive, and Wassermann reaction positive. He received five injections of 0.6 gm. salvarsan, followed by a spinal drainage. Then for three months mercury rubbings were employed. Following this, he received another five injections of salvarsan, with the same dosage, and another spinal drainage. Examination of the spinal fluid revealed 10 cells per cubic millimeter, the globulin test negative and the Wassermann reaction negative.

It took just seven and a half months of this intensive treatment, comprising ten full doses of salvarsan, with continuous mercury rubbings, to bring about the serologic change. The treatment was continued another year, ten more injections of salvarsan being given. The examination of the spinal fluid, Jan. 29, 1917, revealed 5 cells per cubic millimeter, the globulin test negative and the Wassermann reaction negative. In all, the patient received twenty doses of salvarsan. The spinal fluid Wassermann reaction was negative in six months, but the treatment was continued twelve months longer.

Case 6 (38).—R. S. presented evidences of gumma of the testicle with spinal fluid involvement. The blood Wassermann reaction was positive. Examination of the spinal fluid revealed 30 cells per cubic millimeter, the globulin test positive and the Wassermann reaction positive. Treatment was begun, Nov. 28, 1916. The patient received five doses of salvarsan, of 0.6 gm. each, after which a spinal drainage was performed. Examination revealed no marked change in the spinal fluid. Then he had five months of the mercury rubbings, and another five doses of salvarsan, with the same dosage. This was followed by a spinal drainage. Examination of the fluid at this time revealed 3 cells per cubic millimeter, the globulin test negative and the Wassermann reaction negative. The Wassermann test made on the blood at this time was also negative.

The patient showed a negative condition, and it took just ten doses of salvarsan and the mercury rubbings to bring about the change of the spinal fluid after six months of treatment. He is still under treatment.

Case 7 (121).—L. W. K. presented evidences of tabes with spinal fluid involvement. The blood Wassermann reaction was negative. The spinal fluid examination revealed 68 cells per cubic millimeter, the globulin test positive and the Wassermann reaction positive. Treatment was begun, Nov. 15, 1916. The patient received five doses of salvarsan, of 0.6 gm. each, followed by a spinal drainage, which revealed no marked change, and four months of mercury rubbings. Then he was given another five doses of salvarsan and another spinal drainage. Examination of the spinal fluid at this time revealed 4 cells per cubic millimeter, the globulin test negative and the Wassermann reaction negative.

In six months, this patient obtained a complete negative condition of the spinal fluid after ten doses of salvarsan, together with mercury rubbings. He, also, is still under treatment.

It is my purpose to give in a future paper a detailed account of all cases, showing the advantage of the intensive use of salvarsan and spinal drainage over the simple intensive form of treatment.

CONCLUSION

In cerebrospinal syphilis the ideal method of prophylaxis consists in attacking the disease during the primary stage. If correct diagnosis is made and energetic treatment instituted at this period, there should be no further signs of the infection, and subarachnoid involvement would be unheard of. The general aim in treatment, especially among otologists, laryngologists and ophthalmologists, seems to be the healing of the superficial lesions only.

Lumbar puncture, with negative spinal fluid findings, is demanded in every case as final evidence of cure, no matter how energetically the treatment has been carried out.

As a check on possible future complications involving the nervous system, lumbar puncture, with spinal fluid examinations, is demanded in every patient who presents himself for treatment after the primary period.

In view of results of my experience, extending over a year, with intensive salvarsan treatment and mercury rubbings, with spinal drainage, it is my belief that these constitute the most effective mode of treatment, at the same time causing the least danger to the patient.

AN EXPERIMENTAL STUDY OF SURGICAL SHOCK *

PRELIMINARY REPORT

JOSEPH ERLANGER, M.D.
ROBERT GESELL, M.D.
HERBERT S. GASSER, M.D.
AND
B. LANDIS ELLIOTT
ST. LOUIS

"Shock," which we arbitrarily define as a reduction of the arterial pressure to or below 50 mm. of mercury, together with the other usual signs of that condition, has been produced in the dog by (1) exposure and manipulation of the abdominal viscera; (2) a two hour partial occlusion of the inferior vena cava[1]; (3) partial occlusion of the thoracic aorta, lasting two hours; (4) twenty minute intravenous injections of 1:1,000 epinephrin,[2] and (5) the injection into the liver, via the splenic vein, of a suspension of lycopodium spores. Arterial pressure, venous pressure, jugular and portal (in a few experiments), and vasomotor tone have been followed. For the determination of vasomotor tone, a modification of the method used by Bartlett[3] has been employed: From time to time the rate of the flow is determined of salt solution under constant pressure, one high enough to minimize the effects of changing venous and collateral pressures, through a part of the

circulatory system for the time momentarily isolated for the purpose in such a way as not to injure the nerve supply of that part. These injections ("inflows") have been made in the main into the femoral artery; a few into a mesenteric and into the hepatic artery.

At the close of very protracted experiments, lasting, for example, six or more hours, the inflow rate may not be any faster than the normal initial inflow rate, and yet may show little or no mortal acceleration. The cause of this phenomenon is not yet clear. Presumably it is due in part, at least, to the development of a high state of local tone in the larger arteries, and possibly partakes of the nature of the postmortem contraction described by MacWilliam.[4]

SHOCK BY EXPOSURE OF THE ABDOMINAL VISCERA

From two to five hours of exposure and manipulation usually are necessary to reduce the pressure to 50 mm. of mercury. This does not include the time preceding the opening of the abdomen. The experiments usually occupy from about six to eleven hours each. The arterial pressure may be but little affected for several hours. During this time the vasomotor tone is usually somewhat increased, though often it is not outside of the normal range. The tone usually begins to decrease (inflow to increase) as the arterial pressure begins to fall, or to fall more rapidly, and it almost invariably passes below the normal level by the time the arterial pressure reaches shock level (50 mm. of mercury); that is to say, the inflow rate under the constant high injection pressure is then either normal or faster than normal.[5] As has been said, there often is very little further dilatation as the animal dies, though not infrequently there is then a slight constriction (asphyxial?) followed by a slight dilatation, indicating that the vasomotor center, even at the end of long experiments, may not be entirely unresponsive or inactive. On account of the peculiar reaction of the blood vessels at this time, however, it is impossible to form any definite opinion as to the extent of this terminal reserve. Portal venous pressure usually steadily falls throughout the experiment. The jugular pressure (in one experiment) showed no striking change.

THE PRESENCE OF THE ABDOMINAL VISCERA NOT ESSENTIAL FOR THE PRODUCTION OF SHOCK

After the removal of the abdominal viscera, shock develops in from three to five hours. If allowance is made for the greater duration of the preliminary operation, which, as a matter of fact, involves considerable manipulation of the viscera, the time required for the onset of shock certainly is no longer than in uneviscerated animals. The arterial pressure falls in very much the same way as in the uneviscerated. Vasomotor tone, at first, is markedly increased, but as a rule has fallen well below normal by the time shock pressure develops.

SYMPATHETICLESS DOGS

In two animals the abdominal sympathetic chain was removed, and the splanchnic nerves cut several weeks before the experiment. Shock pressure developed in one and one-half and three hours, respectively, after exposure and manipulation of the abdominal viscera. There were no changes in the rate of the femoral inflow. Shock apparently came on more rapidly in the absence of vasoconstrictor activity than in its presence, though it must be borne in mind that these animals were not so vigorous as are animals not operated on previously.

SHOCK BY PARTIAL OCCLUSION OF THE INFERIOR VENA CAVA

The observations of Janeway and Jackson were verified in almost every particular. In addition it was shown that during occlusion, vasomotor tone is usually markedly increased at first and then diminishes, so that before deocclusion (that is, before two hours have elapsed) it is always well below normal. If the arterial pressure improves with deocclusion, the tone may increase; but then it usually does not reach the normal level, and decreases again as the animal goes into shock. With death a further, usually considerable, dilatation occurs. During shock, therefore, vasomotor tone is usually well below normal but not lost. Portal venous pressure may be but very slightly increased by a grade of cava occlusion that eventually produces shock. For example, in one experiment the portal pressure was increased from 8 to only 10 mm. of mercury.

SHOCK BY OCCLUSION OF THE THORACIC AORTA

An obstruction, lasting two hours, of the thoracic aorta just beyond the arch that holds the peripheral arterial pressure at 30 or 40 mm. of mercury usually leads to shock, and usually within two hours after deocclusion, although, as after deocclusion of the vena cava, the arterial pressure after deocclusion of the aorta may for a time be almost as high as before occlusion. Vasomotor tone is markedly decreased during the period of compression, presumably as a result of the improved circulation in the brain. It increases beyond the normal on deocclusion, to decrease again as shock pressure develops, but does not pass below normal until the arterial pressure reaches, or has for some time been below, the shock level. With death, a further and very marked dilatation develops. In no other type of shock does the vasomotor mechanism possess as much residual terminal tone.[6] Portal venous pressure is below normal, excepting, perhaps, momentarily at the time of deocclusion. The jugular pressure does not change materially.

SHOCK BY EPINEPHRIN

Epinephrin administered as described by the British Committee[2] does not often lead to shock. As a rule those injections of epinephrin that do lead to shock cut down the inflow, through peripheral action, almost to zero for a considerable period. Contrary to recent statement,[7] epinephrin contracts the intestinal as well as the somatic arteries, and in these doses it may affect the large arteries (mesenteric, femoral) as well as the arterioles. The inflow method in these experiments gives no clue to the degree of activity of the vasomotor center other than to indicate that it is at least partially active to the end. Portal venous pressure is markedly increased at first, but rapidly falls, and may be below normal long before the animal goes into shock. In many instances death seems to be due to action of the epinephrin on the medullary centers and on the heart, and not to shock; for the heart or respiration may suddenly stop before shock, or even a particularly low arterial pressure, has developed.

---

[4] MacWilliam: Proc. Roy. Soc., 1902, **70**, 109.

[5] Normal vasomotor tone in the presence of a subnormal arterial pressure would result in tissue anemia and pallor.

[6] More recent experiments indicate that the vasomotor centers hold up better in an animal anesthetized with morphin and ether than with ether alone. Inasmuch as morphinized animals require less ether, we are inclined to attribute the difference to the effect of the ether on the centers.

[7] Hoskins and Gunning: Am. Jour. Physiol., 1917, **43**, 399.

SHOCK BY PLUGGING THE PORTAL RADICLES IN THE LIVER

In order to determine whether a portal obstruction resembling in character that which a hepatic constriction would develop will lead to shock, graded injections of lycopodium spores were made into the vena gastrolienalis of the dog toward the liver. A dose that completely obstructs the portal circulation at first raises the portal pressure almost to the arterial pressure. But, presumably through the opening of collateral paths, the portal pressure soon falls until it becomes somewhat less than twice the normal, and this level is then maintained with little change until the animal begins to die. Until the collateral circulation is established, vasomotor tone is markedly increased, but then becomes practically normal. The arterial pressure is falling during this period, and soon arrives at the vicinity of 50 mm. of mercury. Some time later (two and one-half hours in one experiment), vasomotor tone begins to give way, the arterial pressure falls further, and the animal dies, whereupon the "inflow" undergoes a further and rapid increase. The anesthetic can never be completely removed, but toward the end only the lightest anesthesia is needed. Jugular pressure is not materially affected. Doses of lycopodium that do not produce complete obstruction and which, after the establishment of the collateral circulation, almost double the portal pressure, may be sustained indefinitely (four and one-half hours), and may only temporarily disturb the arterial pressure and vasomotor tone.

The rabbit, presumably on account of its longer intestine, is more susceptible to the lycopodium injections. A dose that almost doubled the portal pressure, however, was withstood perfectly by one animal for two hours.

SUMMARY AND COMMENT

Shock evidently may develop during or some time after markedly interfering with the blood supply to a considerable part of the body. It can be brought on by temporary partial obstruction of the inferior vena cava and of the thoracic aorta, by administration of doses of epinephrin that practically stop the circulation for long periods of time, and by the complete plugging of the portal capillaries. Failure of the vasomotor center in shock so produced is not the main cause of the condition, for at the time shock pressure first develops, vasomotor tone may be low, as in shock produced by occlusion of the vena cava; or it may be normal, or even above normal, as in shock produced by occlusion of the aorta. Still, it is important to bear in mind that a vasomotor center that holds the vessels merely to their normal caliber at a time when the arterial pressure is subnormal is not in normal condition. A normal center, under such circumstances, would hold the arteries to less than their normal size. But under any circumstances, the tone of the center falls below normal, if it is not already below normal, very shortly after shock pressure develops, as a result either of fatigue or of deficient blood supply to the center, both consequent, we believe, on the low blood pressure. The tone of the center is never entirely lost until the animal dies. Furthermore, sudden failure of the medullary vasomotor center in an otherwise normal animal apparently does not immediately lower the arterial pressure to the shock level. Increased portal pressure is not the cause of shock as produced by obstruction of the vena cava, or of the aorta, or by epinephrin; for the portal pressure may not be raised at all (as in occlusion of the aorta), or it may be raised only temporarily (as in shock by occlusion of the cava and by the injection of epinephrin). Furthermore, by the injection of lycopodium into the portal capillaries, the portal pressure can be raised as high as or even higher than it may be raised by the aforesaid methods, and yet may not lead to shock. In the dog, at least, obstruction of the portal capillaries to lead to shock must be practically complete; even the rabbit may withstand, almost with impunity, a marked increase in portal pressure.

We conclude, therefore, that by these procedures processes are started peripherally that eventually lead to shock. It is conceivable that shock that is brought on by exposure of the abdominal viscera also owes its origin to peripheral circulatory or nutritional disturbances of the same nature, but limited in this case to the organs maltreated. In the latter type of shock the portal pressure is not increased, and the vasomotor center has begun to fail, by the time the arterial pressure has fallen to 50 mm. of mercury. Before this pressure is reached, the arterioles may be constricted somewhat more than normally. Evidently, therefore, the question as to whether or not the arterioles are actively constricted in this type of shock depends largely on the pressure criterion of shock that is adopted. Indeed, it is possible that if shock pressure could have been induced more rapidly by this procedure, the center might have been found normally or even supernormally active at the time the animals went into shock. Complete vasomotor failure occurs only after death, though the tone residuum seems to be smaller in shock brought on by exposure than in other types of shock.

Obstruction of the portal area alone does not bring on shock as rapidly as an obstruction of the inferior vena cava of the same grade, if the level to which the portal pressure is raised by these procedures may be regarded as a criterion of the grade of obstruction. Presumably, therefore, contrary to Mann's[8] contention, the abdominal area is scarcely more potent in the production of shock than other parts of the body of comparable vascularity. This is indicated also by the fact that shock develops in eviscerated animals as rapidly as, indeed even more rapidly than, in normal animals.

We conclude, therefore, that the sole primary disturbance that leads to shock is not the retention of blood in the veins and capillaries of the splanchnic area, nor failure of the vasomotor center, two views that are quite prevalent at the present time. So far as we have gone, however, our results are not incompatible with the view, now apparently in the ascendency,[2] that the reduced pressure is to be attributed to a reduction in the effective volume of blood. Indeed, practically all of our results can be made to fit into this interpretation. But if this is the correct explanation of shock, our experiments thus far have thrown no light on the mechanism of blood depletion, or on the location of the displaced blood.

Of the five methods by which we have succeeded in producing shock, four, namely, obstruction of the cava and of the aorta, injection of epinephrin, and complete portal obstruction, certainly accomplish this by markedly reducing for some time the blood supply to a considerable part of the body; and it is not impossible that the fifth method (exposure of the intestine) works in a similar manner, the reduced blood supply here possibly being due to the processes associated with the onset of the first stages of inflammation.[9] One of these methods (obstruction of the aorta) undoubtedly leaves practically unaltered the functional capacity of the brain, the spinal cord, the heart, the vasomotor mechanism, etc. For these reasons we have developed the following working hypothesis:

---

[8] Mann: Bull. Johns Hopkins Hospital, 1914, 25, 205.

Long lasting deficient blood supply starts a more or less extensive reaction, possibly of the nature of an inflammation. Engorgement of the small veins and capillaries,[10] and transudation of blood plasma are two of the early consequences of the reaction, and account for the diminution in the effective blood volume of shock. If acidosis occurs in shock, as reports from the front now seem to indicate, might not this acidosis also be the result of the deficient oxidation which deficient blood supply undoubtedly has in its train?

While it is possible so to induce shock (for example, by obstruction of the aorta) as to leave unreduced the functional capacity of many of the organs, we do not entirely agree with the view now current that in shock the heart, the vasomotor mechanism, etc., are always normally active. From the work we have thus far done, we have gained the impression that under the influence of the low blood pressure of shock the heart, while still capable of considerable exertion, has not the normal reserve. Neither does the vasomotor center respond as readily or as markedly to reflex stimulation; it may not be able to hold the arterioles to a normal caliber under a normal pressure, and seems to be set so as to maintain a new and low pressure level, so that in plethora produced by the intravenous injection of glucose,[11] for example, the increased output of the heart fails to raise the arterial pressure materially. We have evidence also that in shock the respiratory center is sluggish, and is working very close to the limit of viability.

Reports from the front[12] indicate that "the occurrence of shock in the wounded soldier when seen soon after the infliction of his wound is exceedingly rare"; it usually appears in patients giving "a history of great exposure to cold and to fatigue during the time which elapsed from the receipt of their injury, to their arrival in the hospital." Such views lend strength to the opinion that laboratory shock is not very different from shock as seen in war surgery. On the basis of such reports, we venture to suggest, as the causative factor of shock, reduced circulation brought about possibly through the action of pain stimuli, and of a certain amount of hemorrhage, on the vasoconstrictor mechanism, this reduced circulation starting in its train such events as follow, for instance, the injection of epinephrin, and the temporary partial occlusion of the aorta, or of the vena cava.

We have not yet succeeded, through stimulation of the vasoconstrictor center, either reflex or direct, in inducing in animals a peripheral constriction of the duration that is necessary, in our experience with other methods, to start the animal on the road to shock. Possibly this can be accomplished only in the conscious animal, and therefore cannot readily be done in the laboratory.

INTRASPINAL TREATMENT OF SYPHILIS OF THE CENTRAL NERVOUS SYSTEM

ANOTHER VIEW

HOMER F. SWIFT, M.D., NEW YORK
Major, M. R. C., U. S. Army; U. S. Army General Hospital No. 1
(Presbyterian Hospital, New York)
FRANCE

In a recent address, Sachs[1] throws discredit on the principles and practice of intraspinal injections in the treatment of syphilis of the central nervous system. It had been arranged that the other side of the subject should be presented by me during the session at which Dr. Sachs made his address, but orders into active military service prevented.

It is naturally impossible to refer to the records and notes on the cases under my care for the past eight years, so that this communication must necessarily be in general terms. In a recent article,[2] however, are published the details in the treatment of cases which represent examples of practically all stages of the disease. As I was naturally interested in the welfare of my patients, both the bedside and the laboratory features of each case were accurately recorded. To neglect either one is not in accord with the modern tendency in clinical medicine. To disregard the laboratory picture of the disease is at least reactionary, for most of our knowledge of the action of drugs has been the result of laboratory investigation. In syphilis, the laboratory evidences of disease are of paramount importance, and changes in them give us a valuable measure of the efficacy of our therapeutic measures. In them also the personal element in measuring change is reduced to a minimum.

In considering the treatment of syphilis of the central nervous system, it is not advisable to throw all the various forms of the disease into one class and have a hard and fixed method of procedure for all. It is always well to separate, as far as possible, the symptoms that are the result of active disease from those that are the result of scars. Obviously, one does not expect to restore scarred nerve tracts or centers. The elimination of active syphilitic foci and the arrest of a progressive degeneration are the objects of our therapeutic efforts.

In the large majority of the tabetics in whom the Wassermann reaction was rendered negative in the blood and spinal fluid, there has been no progressive downward course as determined in periodic clinical examination. On the other hand, in those tabetics in whom it was impossible to influence appreciably the abnormal laboratory findings, the disease was often progressive. The cerebrospinal fluid from these resistant cases often showed a gold curve of the paretic type, and probably the persistence of the Wassermann reaction was due to the paretic nature of the disease. It is my experience, in common with most other workers, that our therapeutic efforts in paresis lead to little more than an increase in the number and length of the remissions. The disease usually terminates fatally. The period of useful life, however, seems to be lengthened, and the period of hospital confinement shortened.

---

[1] Sachs, Bernard: Truth About Intraspinal Injections in Treatment of Syphilis of Nervous System, The Journal A. M. A., Sept. 1, 1917, p. 681.

[2] Swift, H. F.: Response in Treatment of Syphilis of Central Nervous System, Am. Jour. Syph., 1917, **1**, 524.

In considering intraspinal treatment, it is well to differentiate sharply between the injection of salvarsan or neosalvarsan in amounts or concentrations that are injurious to the spinal cord, and the injection of serum, perhaps reinforced with a fraction of a milligram of salvarsan, which is practically never followed by any bladder or rectal disturbance. Although such serum contains only minute quantities of salvarsan, the fact that it is definitely spirocheticidal has been established by several workers. I have shown that the intraspinal injection of normal serum is at times followed by a diminution in pleocytosis and in the strength of the Wassermann reaction. In some cases that were stationary under this form of treatment, there was a further improvement when "autosalvarsanized serum" was substituted for normal serum. Hence we have two favorable factors, namely, normal serum and spirocheticidal substance, at work as the result of the injection of a serum which does not injure the delicate central nervous tissues.

So far as I am aware, nothing has been discovered in the recent work on the anatomy of the subarachnoid space and the physiology of the cerebrospinal fluid that is in any way contradictory to the principle of subarachnoid injection of therapeutic agents. While there has been an occasional report of the finding of arsenic in the spinal fluid after the intravenous administration of salvarsan, by far the majority of investigations have yielded negative results. Therefore, we are justified in concluding that the choroid plexus and the capillaries are usually effective barriers to the passage of arsenic into the cerebrospinal fluid.

In Weed's work on the formation and elimination of cerebrospinal fluid, even though he proved that the direction of the flow was outward from the perineuronal spaces, he did not prove that there was not a free circulation of the fluid. Blackfan and Dandy showed that, after intraspinal injections of finely divided carbon, there was a rapid distribution of the particles throughout the subarachnoid space. They showed also that phenolsulphonephthalein injected intraspinally was demonstrable in the fluid obtained a few minutes later from the ventricles, and that the same dyes could be quickly detected likewise in lumbar puncture fluid after injection into the lateral ventricles. From this evidence we should expect a fairly rapid distribution throughout the subarachnoid space of serum injected intraspinally.

The statement attributed by Dr. Sachs to Amoss, that the virus within the brain and spinal cord in poliomyelitis cannot be reached by intraspinal treatment alone, does not invalidate the principle of intraspinal injection in either syphilis or poliomyelitis.[3] It simply shows that in such diseases it may be well to attack the pathologic condition both through the blood stream and through the cerebrospinal fluid.

In fact, I never contended that intraspinal treatment *alone* was the best or the ideal treatment of syphilis of the central nervous system. The method was advocated only as an addition to other therapeutic measures. In my experimental work, it was necessary to eliminate all other forms of treatment in order to demonstrate that this form, of itself, was of decided value. This I feel I have demonstrated. The question is not one of intraspinal versus intravenous treatment, but of the value of the two methods combined. I have seen patients that did not respond to the intensive general treatment show improvement when intraspinal injections were added to the general treatment. I have also seen patients that showed only moderate improvement under intraspinal treatment alone improve more rapidly when intravenous treatment was added.

Intraspinal injections are not advisable in all cases, because not infrequently general treatment alone is sufficient. But when the general treatment is shown to be only moderately satisfactory, the addition of intraspinal injections is often of decided value.

Furthermore, I do not pretend that the present method is the final one. Doubtless, we may look forward to the time when we shall have drugs that are more efficient than salvarsan when applied both intravenously and intraspinally; but until that time has arrived, we are both obligated to and justified in continuing the use of procedures of determined therapeutic value.

---

[3] In fact, I am not aware that Amoss has published such an exclusive or dogmatic statement. The reference would appear really to be to the combined intraspinal and intravenous serum treatment of poliomyelitis. Since epidemic poliomyelitis is a systemic as well as a special nervous infection, the combined treatment is advocated, not because the intraspinal injections are incapable of reaching all parts of the nervous organs, but because it is desirable to generalize the distribution of the immune serum throughout the body in the shortest space of time.

PHYSICALLY HANDICAPPED CHILDREN

RECOMMENDATIONS FOR OUTDOOR, FRESH-AIR AND OPEN-WINDOW CLASSES *

ADELA J. SMITH
Assistant Director of Physical Training for Physically Handicapped Children
FRANCES COHEN, M.D.
AND
I. H. GOLDBERGER, M.D.
Assistant Directors of Educational Hygiene, New York City Public Schools
NEW YORK

The beneficial results obtained through open-air treatment of respiratory diseases, particularly pulmonary tuberculosis, have influenced educational hygienists, as well as physicians, to adopt similar methods for the care and treatment of other disabilities common among schoolchildren.

Among the 800,000 children attending the New York City public schools there are hundreds of physically handicapped children, including those affected with active pulmonary tuberculosis, and with bone, skin and glandular tuberculosis. There are also many pretuberculous, anemic and crippled children, and cardiac cases. As these children cannot attend the regular classes, provision must be made for their comfort, health and progress in school by some process of segregating them into special classes, of providing special classroom and personal equipment, and a relaxed curriculum.

Because of the varied types of physical defects, and of the different kinds of treatment necessary, these children cannot be grouped in any one type of classroom. Since this is true, we believe in the segregation of groups of physically handicapped or subnormal children, according to the type of case, into (1) outdoor classes, (2) fresh-air classes, and (3) open-window classes, as outlined in the accompanying table. A system of segregation which partly embodies the recommendation contained in this article is at present in operation in the public schools of New York City.

---

* From the Department of Physical Training and Educational Hygiene, Department of Education, New York City.

OUTDOOR CLASSES

All cases of active pulmonary tuberculosis should be placed in classrooms of this type. A distinction should be made, however, between cases of active pulmonary tuberculosis and all other types of active tuberculosis.

Classrooms for children suffering from active pulmonary tuberculosis should be located on ferry boats, in parks, on piers, on hospital roofs, etc., but never in school buildings. In addition to the outdoor classrooms, provision should be made for a heated indoor lunch room on the same floor. When hospital roofs are utilized, stair climbing should be eliminated, through the use of an elevator. These classes are situated outdoors, and the outdoor temperature and adverse weather conditions may be partly regulated by movable glass wind and storm shields, which permit the passage of sunlight. Under the systems in use at the present time, canvas curtains and other cloth materials are used for wind shields. These are unhygienic from several points of view. They do not transmit sunlight, or prevent drafts, and they become dusty from prolonged use.

RECOMMENDATIONS FOR OUTDOOR, FRESH-AIR AND OPEN-WINDOW CLASSES

Type of Classroom	Special Groups	Type of Case	Temperature	Type of Structure				Type of Room Equipment	Type of Personal Equipment
				Structure	Location	Ventilation	Heating		
I Outdoor	1	Pulmonary tuberculosis (active)	Outdoor temperature regulated by glass storm shields	Outdoor room; no walls; movable glass wind and storm shields; also a warm indoor lunch room	On ferry boats, piers, hospital roofs, in parks, etc., but not in public schools; stair-climbing to be avoided	Direct	No artificial heat	A specially constructed adjustable movable chair resembling a Morris chair with desk attachment, rendering but one furniture equipment necessary for sitting and sleeping purposes; this is an evident economy; at present, desks, seats and cots are used	Wind-proof outer garment, with hood attachment—an outfit which may be easily washed so as to be sanitary Foot covering—Sitting out canvas-covered knee boots with felt insoles Army blankets—For use on very cold days, or when sleeping Bloomers — For additional warmth, if necessary, the girls wear bloomers under their skirts Sweaters, coats, caps and mittens are provided by the children, since these are articles of clothing commonly in use by all
II Fresh-air	1	The pretuberculous, i. e.: (1) Children exposed daily to tuberculosis in their homes (2) The so-called malnutrition and anemic type (3) Gland and skin tuberculosis	Not higher than 50 F.	Indoor room; specially constructed pivoted windows, so as to admit as much fresh air as possible without drafts	Corner room southern exposure, not higher than one flight	Direct	1. Artificial heat	Same as outdoor classroom	Same equipment as outdoor classroom
	2	Pulmonary tuberculosis (arrested)					2. Artificial heat		
III Open-window	1	Normal children attending regular classes	From 50-60 F.	Open window with specially constructed window ventilators	1. Any floor	1. Direct	1. Artificial heat	1. Regular classroom equipment	Sweaters, coats, leggings, mittens, caps, and bloomers for the girls
	2	Subnormal children, i.e.: (1) Children discharged from fresh-air classes (2) Children predisposed to respiratory diseases other than tuberculosis (3) Possible cardiac cases: i.e., doubtful murmurs, mainly functional (4) Mild chorea cases (5) Selected organic cardiac cases			2. Any floor	2. Direct	2. Artificial heat	2. Regular classroom equipment	
	3	Cases of organic cardiac disease in which further school segregation and prophylactic care are indicated			3. Not more than one flight	3. Direct	3. Artificial heat	3. Special equipment as in fresh-air class	
	4	Classes for cripples: A. (1) Cripples, nontuberculous, poliomyelitis cases, etc. (2) Cardiac cases in which school transportation is indicated B. Cripples; bone tuberculosis of all types			4. Not more than one flight	4. Direct	4. Artificial heat	4. Special adjustable equipment	

Since body heat must be provided through the child's own activities, not only should there be sufficient space for classroom activities and exercises through the use of movable furnishings, but the personal equipment of the child should permit unhampered activity. For these reasons, movable chairs should replace fixed desks and seats. A specially constructed chair, now in process of construction, is recommended. It resembles a steamer chair or Morris chair with a desk attachment. It is adjustable, and furthermore, it can be used for sleeping purposes, rendering necessary only one set of classroom furnishings. This arrangement is a distinct advantage to the physical well-being of the child, as well as an economical provision. In the planning of classroom equipment, it is essential to take into account the need of a period for rest or sleep immediately after the noonday meal, a health measure which prominent specialists recommend for physically handicapped children, such as those suffering from carditis and tuberculosis. A careful consideration of the dietary of the physically handicapped child, both at school and at home, is of prime importance, and necessitates home visiting on the part of the teacher and the school nurse.

For the personal equipment, certain essential garments and coverings are recommended. This includes a wind-proof outer garment with hood attachment, an outfit easily washed, and therefore sanitary. Over the shoes a foot covering consisting of sitting-out canvas-covered felt knee boots with felt insoles is worn. These are warm and well ventilated, in contrast to the rubber arctics sometimes worn, which make the feet cold and damp by causing excessive perspiration.

An army blanket should be used on very cold days, or when the child is sleeping. It is hygienic because it is easily cleaned. The sleeping bag now commonly in use limits the physical activity of the child, and is a menace, because it rapidly becomes unhygienic and hazardous from the standpoint of dust, vermin and contagion, and, in addition, is difficult to clean. Furthermore, this cumbersome, immobilizing equipment is a real danger during fire drills and other emergencies.

Bloomers should be provided for additional warmth if necessary, to be worn under the girls' skirts. These may be made in the sewing department of the school. Sweaters, coats, caps and mittens should be provided by the children, since these are articles of clothing commonly in use by all.

It is evident that this type of personal equipment furnishes sufficient warmth, even on the coldest days, and allows the child opportunity for unhampered activity and physical training, besides being a great asset in times of fire drill and other emergencies.

FRESH-AIR CLASSES

Two special groups of physically handicapped children are included under this classification. The first group includes the pretuberculous children, that is to say, those exposed daily to tuberculosis in their homes, those suffering from malnutrition or anemia, and those suffering from gland and skin tuberculosis. The second group consists of children in an arrested stage of pulmonary tuberculosis.

The fresh-air classroom should be an indoor room located not higher than one flight, in order to eliminate excessive climbing of stairs for physically handicapped children. Preferably, it should be a corner room with a southern exposure, provided with specially constructed pivoted windows, to admit as much fresh air as possible without draft. Artificial heat should be available, but care should be taken to prevent the temperature from exceeding 50 F. The same type of classroom and of personal equipment recommended for use in the outdoor classrooms should be used in the fresh-air classrooms. A lighter weight personal outfit may be used, because of the higher temperature of the rooms. Similar methods should be observed in regulating the diet and periods of rest for children in these classes.

OPEN-WINDOW CLASSES

Four special groups are included in this classification. The first is made up of the normal children attending regular classes. The second includes physically subnormal children, those discharged from fresh-air classes, those who are predisposed to respiratory diseases other than tuberculosis, those who display possible cardiac symptoms, such as doubtful murmurs, mainly functional, those showing mild symptoms of chorea, and selected children showing symptoms of organic cardiac disease. The third group consists of the cardiac patients who require further school segregation and prophylactic care. The fourth group comprises the crippled children. To this group belong the nontuberculous cripples, that is to say, those suffering from poliomyelitis, scoliosis, spastic paralysis, congenital malformation, amputations, progressive muscular dystrophy, etc. It also includes children with cardiac diseases for whom transportation is indicated, as well as cripples suffering from bone tuberculosis of all types.

The open-window classroom requires no structural changes. The ventilation should be direct, fresh air being admitted through open windows equipped with specially constructed window ventilators, to prevent drafts. Under present methods, the open windows are not equipped with window ventilators, and the children are exposed to drafts. The temperature in the rooms should be maintained at a point between 50 and 60 F., by the use of artificial heat. The classrooms for crippled children and for those having marked chronic organic diseases should be located not higher than one flight up. The restriction need not apply to the location of open-window classes for normal and subnormal children designated in the accompanying table, in Groups 1 and 2 under the third section. There is also no need of special furnishings for these two groups. The crippled children and the cardiac patients needing special segregation, however, require adjustable school furniture carefully adapted to their physical disabilities.

It is the opinion of cardiac specialists that certain cardiac patients require rest in school, prone. Therefore, a chair of the type recommended for use in fresh-air classes, adaptable for both school work and sleeping purposes, should be used, rendering but one classroom equipment necessary.

Crippled children require a still more specialized type of adjustable furniture, because of the various kinds of mechanical appliances used in the treatment of their orthopedic defects. It is evident that the long iron leg brace, plaster hip spica and plaster jacket present definite problems of seating, which must be solved by the structural adjustment of the furniture. The furniture now in use for classes of crippled children in the New York City public schools solves these problems. Both desk and seat have a central floor support, instead of the side supports of regular furniture, and are fastened to the floor. This provision leaves ample floor space, both for the locomotion of crutch patients, and for full extension of rigid limbs of brace patients, when the latter are seated. Aisle spaces should not be less than twenty-four inches wide.

The desk top is so constructed that a variable plus or minus distance of great range may be instantly obtained to meet the special seating needs arising from the mechanical appliances worn by the crippled child.

The vertical adjustment is readily made by means of a hand screw on the central supports.

The seat is provided with an adjustable back, similar to that of a Morris chair, with a cane center to prevent undue pressure. This cane back is removable, so that all pressure on sensitive spines may be prevented. The front half of the chair seat is divided anteroposteriorly into adjustable sections, which may be lowered to various angles to meet the requirements of the various types of leg braces. The seat is pivoted, revolving on ball bearings in an arc of 180 degrees, to provide greater mobility and facility for the crippled child in sitting and standing. Additional accessories in seating for the comfort of the child include foot rests, foot braces and air cushions.

Each classroom for nontuberculous cripples is provided with a cot, a sleeping chair and a blanket for emergency use. Each classroom for children with bone tuberculosis is equipped with a cot or a sleeping chair and a blanket for each child to meet the orthopedists' recommendations of a sleeping period in school for this group.

Crippled children are provided with transportation by stage to school and to their homes.

When greater warmth is necessary, children in all open-window classes should be provided with sweaters, coats, leggings, mittens, caps and bloomers for the girls, in addition to their skirts. As these are articles of clothing in common use, no additional expense for personal equipment is needed. The personal equipment of the teacher should be similar in character to that worn by the children in the special class to which she has been assigned.

SUMMARY

1. The type of physical defect should be the basis for the segregation of groups of physically handicapped children in special types of classrooms, that is to say, outdoor, fresh-air and open-window classrooms.

2. The range of temperature is governed by the type of physical defect in each special group.

3. Glass wind and storm shields are recommended to admit light and regulate heat, replacing the canvas or wood protectors now in use. Specially constructed window ventilators should be installed in all open-window classes, to prevent drafts and to protect children seated near the open windows.

4. No classroom for physically handicapped children, with the exception of the kind mentioned in Groups 1 and 2, of the third section in the accompanying table, should be located higher than the second floor unless an elevator is available.

5. In outdoor and fresh-air classes, movable, adjustable chairs are recommended instead of fixed desks and seats. This equipment could then be used for sleeping, rendering but one set of classroom furnishings necessary. A movable equipment in outdoor and fresh-air classrooms has the following additional advantages: (*a*) Direct drafts on children are easily avoided. (*b*) Greater space for classroom activities and physical training is provided. (*c*) The children are permitted greater freedom. In classes for cripples, additional mobility is made possible through specially constructed desks and pivotal chairs.

6. The type of personal equipment should allow the greatest possible freedom for schoolroom activities and physical exercises, and should eliminate the danger arising from fire drills and other emergencies. It should also be sanitary, so as to be easily cleaned. The type of equipment commonly in use fulfils none of these requirements. Before a child is placed in a special classroom with lowered temperature, he should be provided with sufficient underwear and appropriate outer clothing, as well as storm equipment, so that he may not feel the effects of exposure when he leaves the classroom at the end of a school session.

THE MORTALITY FROM PELLAGRA IN THE UNITED STATES

WILLIAM F. PETERSEN, M.D.

CHICAGO

By force of circumstances, greater attention is at present being directed toward dietary problems than ever before. The growing disproportion between a practically stationary income and an increasing cost of foodstuffs has resulted in considerable hardship during the past few years, and has brought with it an accentuation of diseases commonly associated with deficiencies in diet, such as pellagra and scurvy. Profound alterations in the labor market have led, furthermore, to a far-reaching migration from southern agricultural to the northern industrial centers. Under such circumstances it is appropriate at this time to discuss briefly the recent pellagra statistics, and to call attention to the widespread distribution of the disease in the United States.

TABLE 1.—PELLAGRA MORTALITY IN THE NORTH ATLANTIC STATES *

	Deaths	
	1915	1916
Maine	10	15
New Hampshire	5	10
Vermont	3	3
Massachusetts	26	37
Connecticut	1	1
Rhode Island	8	7
New York	12	27
Pennsylvania†	?	?
New Jersey	5	4

* Population, 29,246,000; deaths, 1915, 70; 1916, 104; mortality per hundred thousand population (excluding Pennsylvania), 1915, 0.33; 1916, 0.5.

† No statistics available.

TABLE 2.—DEATHS FROM PELLAGRA IN THE SOUTH ATLANTIC STATES *

	Deaths		Rate per 100,000 Pop.	
	1915	1916	1915	1916
Delaware	0	0	0	0
Maryland	15	3	1.1	0.2
District of Columbia	16	9	4.4	2.5
West Virginia†	?	?	?	?

* Population, 13,343,000; deaths, 1915, 5,049; 1916, 2,524; mortality per hundred thousand population (excluding West Virginia), 1915, 42; 1916, [illegible].

† Deaths reported, but the total number not available to the state health office.

‡ No statistics collected in Georgia; the mortality given is estimated.

§ Statistics incomplete.

That the diet is of basic import, either as a contributing factor or as the etiologic agent in producing pellagra, has been generally accepted by observers, although it must be admitted that no one interpretation of this relation to the disease has been definitely accepted. The corn ration more or less prevalent in the pellagrous districts is not in itself responsible, although it may be one of a number of factors that tend to bring about a state of nutritive deficiency, since zein, the chief protein constituent of the corn, is the only one of the commonly used proteins that is definitely lacking in certain of the amino-acids. The more recent work of Goldberger and his associates has done much to confirm Funk's contention that the disease is due to a vitamin deficiency.

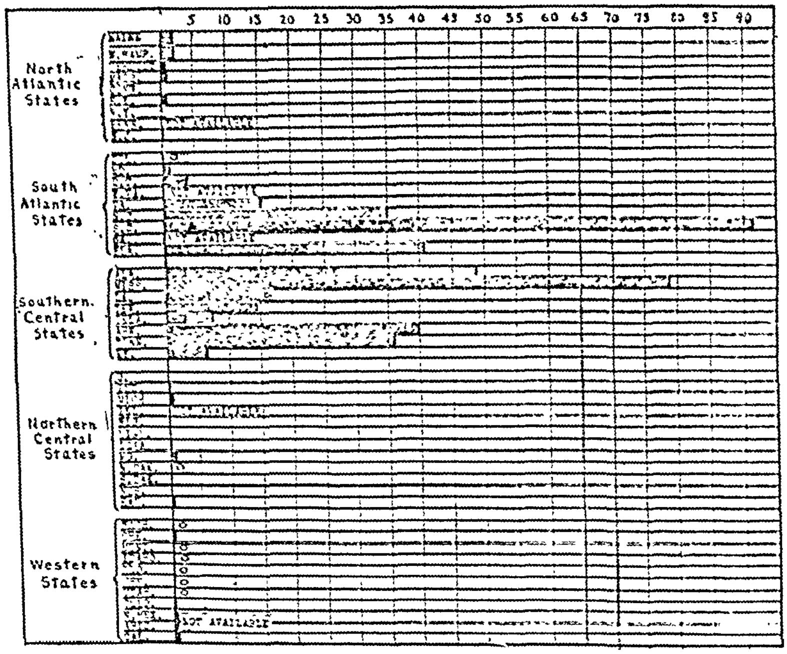

Fig. 1.—Graphic representation of pellagra mortality per hundred thousand population during 1915 and 1916. Shaded columns indicate mortality in 1915; black columns indicate mortality in 1916.

The possibility is not excluded that, instead of dealing with a deficiency, we have to do either with an intoxication from the absorption of toxic products originating in the intestinal tract and related to an altered flora (that such bacterial changes occur has been repeatedly demonstrated), or that a specific organism, as yet not isolated, causes the disease. The epidemiologic data collected by the Thompson-McFadden Commission and by Jobling in Nashville can be interpreted as lending support to the latter hypothesis.

The attention of the profession was directed to pellagra at a time when a rapid increase in the number of cases followed a period of financial stringency (1907-1908). This early period was probably followed by one in which the actual number of cases decreased, although the statistical evidence of this decrease was apparently negated by the increase in the number of cases that were correctly diagnosed. This period was followed by one of very definite and continuous increase in the mortality rate, until a maximum was reached in 1915, the number of recorded deaths for that year being well over 10,000.

In Tables 1-5 the states have been grouped and the pellagra mortality, as reported to the state health officers, has been collected; the graphic representation of the statistics is shown in Figure 1.

THE REDUCTION IN THE MORTALITY RATE

It is at once apparent from Tables 1-5 that a striking reduction in mortality took place during the year 1916, the total number of deaths recorded for 1915 being 10,663, while during 1916 only 6,289 were recorded in the state health offices. This reduction was of greatest extent in the South Atlantic group of states, where the mortality declined from 42 to 21 per hundred thousand population.

When the figures are examined on the basis of race (Table 6) it will be observed that a greater reduction occurred in the colored than in the white race.

INCREASE IN MORTALITY IN THE NORTH ATLANTIC STATES

While a decrease occurred in the chief pellagrous districts, it is rather interesting to observe that in the New England states the mortality, although still low, practically doubled during the year 1916, so that the death rate for Maine and Vermont, for instance, is almost as great as in some of the states directly bordering the pellagrous area.

THE STATISTICAL AND THE ACTUAL MORTALITY RATE

There is very little doubt that the diagnosis of pellagra submitted on the death certificates to the various state health offices is almost invariably correct. The statistics err only in the omission of a vast number of deaths actually due to pellagra but improperly entered on the records as deaths due to other causes. It is very probable that the actual mortality from the disease is from 50 to 75 per cent. greater than is indicated in the statistics presented. This condition is brought about by the following causes: Pellagra, contrary to the usual opinion, is a relatively chronic disease in the white race, and the death, when it does take place, is almost invariably attributed to the diarrhea or its resulting inanition. Symptomatic diagnoses, such as

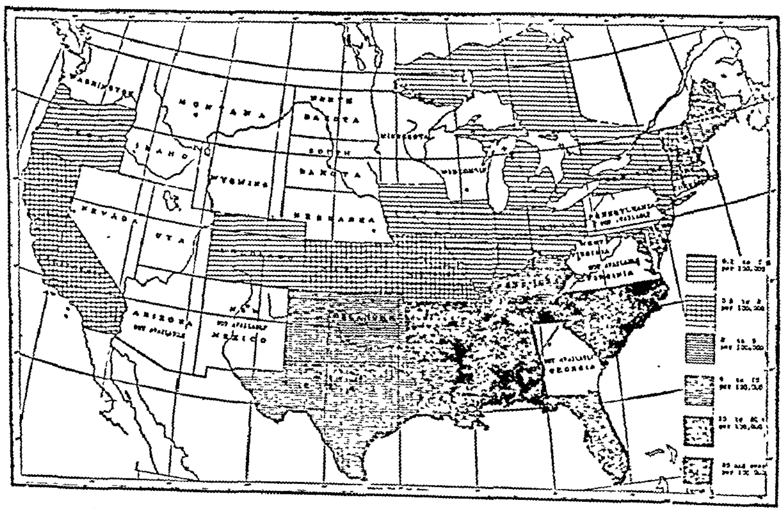

Fig. 2.—Pellagra mortality of the white race in the United States.

dysentery, tuberculosis of the intestine, and chronic gastro-enteritis, are found commonly recorded for deaths due to pellagra, as well as symptomatic diagnoses referable to the changes resulting in the central nervous system. We have also to consider that a certain number of deaths recognized by the physician as due to pellagra are not entered by that name on the death certificate because of the prejudice on the part of the laity to a diagnosis involving to a certain extent the social status of the family.

THE MORBIDITY FROM PELLAGRA

Health authorities in the Southern States estimate that approximately 0.5 per cent. of the population is frankly pellagrous. With a population of about 32,500,000 in the pellagrous area, this would mean that there are some 165,000 pellagrins.

It has been estimated by others that for each death from pellagra there are at least fifteen living patients. This ratio applied to the mortality figures for 1915 would result in an estimated total of 157,000. Both of these estimates are undoubtedly greatly below the actual morbidity.

SUMMARY

While the accompanying map (Fig. 2), showing the distribution of the pellagra mortality for the white race during 1916, illustrates that pellagra is still predominantly a disease of the Southern States, nevertheless, deaths occur with considerable uniformity in all states with the exception of those in the northwest part of the country. In Canada, deaths from pellagra have been recorded[1] only in the Province of Ontario, although undoubtedly isolated cases occur in other parts of the Dominion.

TABLE 3.—NUMBER OF DEATHS FROM PELLAGRA IN THE SOUTH CENTRAL STATES *

	Deaths		Rate per 100,000 Pop.	
	1915	1916	1915	1916
Alabama	1,109	677	48.4	26.6
Mississippi	1,535	840	79.0	43.0
Louisiana	301	295	16.6	16.4
Texas	661	452	14.5	10.0
Oklahoma	152	71	7.2	3.2
Arkansas†	680	500	40.0	28.0
Tennessee	830	607	36.0	26.0
Kentucky	150	120	6.5	5.0

* Population, 19,270,000; deaths, 1915, 5,418; 1916, 3,562; mortality per hundred thousand population, 1915, 28; 1916, 19.

† The mortality for Arkansas is estimated. In 1915, when about 70 per cent. of the deaths were recorded, 477 deaths were reported due to pellagra. The 1916 statistics are not as yet available, and have been estimated as having decreased in the same ratio as those of Tennessee.

TABLE 4.—SUMMARY OF PELLAGRA MORTALITY IN THE NORTH CENTRAL STATES *

	Deaths	
	1915	1916
Ohio	5	6
Indiana	7	4
Michigan	12	4
Illinois†	?	?
Wisconsin	1	0
Minnesota	0	1
Iowa	5	4
Missouri	42	39
North Dakota	0	0
South Dakota	1	0
Nebraska†	?	?
Kansas	21	10

* Population, 32,315,000; deaths, 1915, 94; 1916, 68; mortality per hundred thousand population (excluding Illinois and Nebraska), 1915, 0.37; 1916, 0.27.

† Statistics from Illinois and Nebraska not available.

The maximum mortality was evidently reached during 1915; since then the number of deaths has diminished. In the colored race the decrease in the mortality has been proportionately greater than in the white race. With the migration to the Northern States of large numbers of colored people, it is very probable that a considerable number of pellagrous individuals will have been included.

Regulations Governing the Dispensary Treatment of Tuberculosis.—The department of health of New York City has recently amended the sanitary code to provide that "no public dispensary where communicable diseases are treated or diagnosed shall be conducted or maintained otherwise than in accordance with the regulations of the Board of Health." This amendment includes ten regulations requiring that the examination and treatment of persons affected with pulmonary tuberculosis be conducted in a special dispensary or department of a dispensary; that proper microscopic examinations of sputum shall be made; that the maximum number of patients examined shall not exceed five an hour; that the necessary medical and nursing staff shall be on duty on all days set apart for the reception of patients; that a proper follow-up system be maintained, that circulars of instruction and advice shall be furnished, and that all applicants be examined at the time of their first visit, irrespective of their place of residence; that an adequate supply of approved sputum receptacles be provided and the use of cuspidors be prohibited; that complete and adequate records be kept of every case of pulmonary tuberculosis examined, such records not to be open to inspection by the public other than the representatives of the Department of Health of the City of New York and such persons as may be authorized by the law to inspect such records; and that every department of a dispensary wherein persons are treated for pulmonary tuberculosis shall employ proper facilities for the examination and treatment of the nose and throat lesions.

ETIOLOGIC FACTORS IN GROSS LESIONS OF THE LARGE JOINTS

OBSERVATIONS FROM ONE THOUSAND ONE HUNDRED CONSECUTIVE NECROPSIES *

HERBERT C. CLARK, M.D.
ANCON, CANAL ZONE

The routine performance of a necropsy, generally speaking, does not include a section and an examination of the joints unless the clinical history or the external appearance of the joint happens to indicate the presence of arthritis. There was no departure from this rule at Ancon until Dr. L. B. Bates began the application of the Wassermann test. He soon noticed that a number of the laborers who responded in a positive manner to the test had associated with their clinical history an ill defined type of arthritic symptoms. This feature became so significant among the negro laborers that Dr. Walter Baetz,[1] then in charge of the negro medical service, made a clinical study of the acute arthritic conditions occurring in his service. In his report, in 1913, of 100 cases of acute arthritis among negro laborers in the Panama Canal Zone, he thus named the types according to the frequency of their etiologic factor; syphilitic arthritis, 63; gonorrheal arthritis, 28; undetermined arthritis, 6; dysenteric arthritis, 2, and tuberculous arthritis, 1.

The important position given to syphilis in this report was so surprising that it stimulated some interest in what might be found at necropsy. Since the report of Baetz, others have occasionally appeared which also indicate the importance of syphilis in this respect. A study of the joints in 200 necropsies in Berlin showed that after exclusion of the typical types of joint disease there still remained in this series 178 bodies without a typical type of arthritis which revealed macroscopically visible changes in the joints in at least 143 individuals.[2]

Various textbooks on clinical medicine and on pathology grant but small space to a discussion of syphilis and age respecting lesions in the joints. In the fullest account to which I have ready access[3] is the statement:

> Syphilitic affections of the joints make their appearance either at the time of the secondary eruptive stage or in the tertiary stage of the disease. In the secondary stage the affection takes the form of a serous synovitis, resembling that associated with acute articular rheumatism. In rare cases a like effusion takes place even in the later stages; but as a rule the tertiary syphilitic arthropathies are of a chronic kind, and are characterized by the formation of gummatous nodes and thickenings in the capsule, proliferation of the synovial membrane, and fibrillation and erosion of the cartilage. Syphilitic arthritis may occur as a primary affection of the joint, or may be due to the extension into it of specific inflammation from the periosteum or bone marrow.

Since so little could be found regarding the incidence of gross pathology in the joints, and especially regarding the possible relation of syphilis to joint lesions, it seemed desirable to follow the local clinical observations with some anatomic observations. It was arranged to do a Wassermann test in all cases with a grave prognosis, and in the event of no antemortem test, to apply it to the postmortem serum whenever it was in a satisfactory state for analysis. To the routine necropsy examination was added a section of the large joints: the shoulders, hips and knees. Other joints were opened only when there was a clinical history or gross external evidence of disease in them or when extensive change was noted in the large joints mentioned.

It is common knowledge that a necropsy often reveals a lesion in the middle ears, accessory sinuses, tonsils, gallbladder, duodenum, appendix and the genito-urinary system that had not declared its presence, or had had its clinical picture obscured by the more important disease present at the time of death. With this fact in mind, it is to be expected that a joint might be the seat of a lesion which represents a remote sequel to a disease that may be little related to the disease causing death.

It is not the intention to include in this series of cases all those showing very small areas of degenerative change in the cartilages, such as flattening and change of color at the points of pressure, or effusions such as commonly occur in the joint cavities just as in other serous cavities in some chronic diseases. Only those joint changes are to be discussed which have offered a *well defined gross lesion* of the cartilages, bone or joint content. Since the inauguration of this method of examination, 1,100 necropsies have been performed. Less than 1 per cent. of these individuals were considered "arthritic suspects," yet 172 cases offered some significant type of a well defined gross lesion. It is quite impossible thoroughly to dissociate the various etiologic factors known to produce arthritis in the discussion of this series, since many of the individuals had a remote history or the present evidence of more than one possible etiology. As in many such studies, the matter resolves itself into the expression of a personal opinion; and after weighing the general findings, both clinical and pathologic, surrounding these cases, I am led to arrange them in the order given in Table 1.

TABLE 1.—ETIOLOGIC FACTORS IN ONE HUNDRED AND SEVENTY-TWO CASES OF ARTHRITIS

	Number of Cases
Syphilis	96
Arteriosclerosis	33
Gonococcus	10
Undetermined	10
Streptococcus	6
Staphylococcus	5
Tuberculosis	4
Pneumococcus	2
Meningococcus	2
Trauma	2
Pellagra (?)	1
Scurvy	1

A classification for the sake of convenience in further analysis is necessitated, and therefore the 172 cases have been arranged in three groups (Table 2). Group 1 includes all cases showing a degenerative type of lesion associated with a positive Wassermann test, or with supportive lesions of syphilis found at necropsy, or with the history of having been treated for syphilis. Group 2 includes only those showing a degenerative lesion associated with arteriosclerosis and not showing the presence of any other factor acute or chronic in type. Group 3 includes all well recognized types of arthritis and the undetermined acute types.

[2] Beitzke, H.: Ueber die sog. Arthritis deformans atrophica, Ztschr. f. klin. Med., 1913, 74, 215, cited in Current Comment, The Journal A. M. A., Sept. 6, 1913, p. 779.

[3] Ziegler, Ernst: A Text-Book of Special Pathological Anatomy, pp. 285, 286.

Practically all the bodies were of negroes or of negro mixtures. Nearly all were of persons who had been hard laborers, tradesmen on their feet all day, or domestic servants and laundresses. Of the cases listed under syphilis and arteriosclerosis (Groups 1 and 2), about 80 per cent. of the deaths had occurred as a result of chronic cardiovascular disease, renal disease or chronic disease of the central nervous system (many of the persons had been insane).

The Wassermann test on the blood was positive in sixty-six of the ninety-six cases in Group 1; in two additional cases there was a positive spinal fluid test, eight could not be tested, and in nineteen there was a negative response but a history of syphilis, and supportive lesions of the disease at necropsy. The various special tests for the spinal fluid were not applied to the cases in this series.

Totals........	1,100	96	33	43

Table 3 gives a list of some of the lesions found associated with the cases under Group 1 and believed to be "supportive lesions" of syphilis.

It is not considered important to discuss the cases in Group 3, since they were all well defined acute types that have already been indicated. Several of these cases, however, represent a secondary invasion by an acute factor of a joint already the seat of the chronic degenerative type of arthritis about to be described, and it is to be expected that such a joint, with its plates eroded and its nutrition below normal, would frequently favor the localization of an acute process.

The lesion found in the cases under Groups 1 and 2 were identical in character, and therefore the description of the lesion found in Group 1 will suffice.

LESION IN THE UNCOMPLICATED CHRONIC DEGENERATIVE TYPE OF ARTHRITIS

The knee, being the most common location of the process, is best suited to illustrate the lesion. The external examination of the joint seldom offered any sign of the change to be exposed by the disarticulation of the joint. The cavity was usually almost dry or partially filled with a straw colored, transparent, gelatinous material. The synovial membrane many times presented no visible change, but infrequently it was found thickened, red and granular, and more infrequently containing a polypoid growth with a little flaky material or perhaps some free pieces of cartilage floating in the scanty joint fluid. Adhesions spanning the joint cavity between the bone surfaces were almost never found. The most common and significant change to be found was located in the cartilages at the points of the greatest "occupational pressure." The cartilage of the patella, and the condyles of the femur and of the head of the tibia were in many instances almost destroyed; but the majority of the cases revealed a loss of substance in the cartilages only in those regions subjected to the greatest and longest continued pressure strain in the daily use of the joint. The buffer influence of the semilunar cartilages in most instances saved the tibia from extensive involvement; but the center of each condyle, the groove between the condyles at a little higher level, and the surface of the patella suffered such extensive losses of cartilage that comparatively large areas of bone were exposed. Many times this bony bed would be rough, red and cancellous in character, while at other times it was a polished, red surface. No pus or fibrin filled these exposed places, and granulations were seldom present. The patella appears to be the first to suffer, as a general rule; since, in what is considered to be the earliest stage of the process, the cartilage of this bone shows the most extensive softening, fibrillation and lemon color, and this condition is often present when the other bones show but scant involvement. The final stage of the lesion appears to be represented by those cases revealing complete absorption of the cartilages and exposure of large areas of bone at points corresponding to the pressure areas.

COMMENT

The character, position and size of the joint lesion strongly suggest a degenerative result and absorption rather than the local action of micro-organisms, although such a joint could well be expected to favor a secondary invasion by some pyogenic factor, since its devitalized condition and constant use would facilitate the localization.

It is believed that chronic vascular disease, such as syphilitic arteritis and arteriosclerosis, reduces nutrition to the joint plates, and that at the "pressure areas" nutrition is further reduced by the hard daily use of the joint, so that degeneration and absorption of the cartilages take place, finally resulting in the exposure of the bone, and being usually limited to the areas of greatest pressure. Many of the persons in this series from early life had been in the habit of carrying burdens on their heads. Frequently this load would be greater than the same person could have carried by hand. This no doubt materially increased the strain on the hips and knees, and may account for the great incidence of the knee lesions; although this joint, being a large one situated between two important epiphyses and subjected to the strain of long, large bone levers supplied by many groups of powerful muscles, is to be expected to reveal this type of lesion more than any other joint.

TABLE 3.—SUPPORTIVE LESIONS IN GROUP 1

Chronic types of meningitis and focal areas of brain sclerosis......	10
Gummas	5
Chronic orchitis	5
Arteritis obliterans	4
Chronic leg ulcer	3
Iritis	2
Rectal ulcer (stricture)........	1

It appears reasonable to suppose that syphilis may be frequently an important preliminary factor in producing this type of joint lesion. The results in the vascular system of an untreated course of syphilis are today well known, and a glance at the ages of the persons comprising Group 1 of this series will reveal a large number of adults in the early decades of life, periods earlier than senile changes are to be expected, although the lesion present resembles such a change. The summary[4] of the year's work in this laboratory for the year 1916 showed that 3,947 negroes and mulattoes were examined by a Wassermann test and that 30 per cent. were positive. When it is recalled that the 1,100 cadavers in this series of necropsies were of unselected persons with regard to the test, and that ninety-six out of 172 joint cases could be placed in Group 1, the relation of syphilis to these degenerative lesions seems to be more than mere coincidence. Syphilis and arteriosclerosis are indicated as important preliminary factors in preparing the joint plates for the development of degenerative arthritis.

TABLE 4.—DISTRIBUTION OF JOINT LESIONS

Location	Syphilis Associated: Group 1	Arterio-sclerosis: Group 2	All Other Forms: Group 3
Right knee	90	33	28
Left knee	92	32	28
Right hip	17	7	6
Left hip	9	6	4
Right shoulder	17	10	4
Left shoulder	8	9	5
Right elbow	2	0	3
Left elbow	2	0	2
Right ankle	2	0	4
Left ankle	3	0	1
Right wrist	1	0	0
Left wrist	0	0	0
Spine	1	0	2
Digits	0	0	1

These degenerative changes in the joints may represent the remote results of what Baetz has named, in the secondary period of the disease, "syphilitic arthritis."

Certainly the gross pathologist, in the absence of arteriosclerosis, should look on this condition when present in the body of a young adult as suggestive of syphilis, and apply the laboratory tests for the disease.

SUMMARY

1. Gross lesions of arthritis were found in 15.6 per cent. of 1,100 consecutive necropsies, and less than 1 per cent. of those showing the lesions were considered "arthritic suspects."
2. All but two of the persons showing arthritis were hard working adults belonging chiefly to the negro race.
3. A chronic degenerative type of arthritis included 129 of the cases, while forty-three cases were well known acute types of arthritis or some ill defined acute and chronic types combined.
4. Chronic vascular disease (syphilis and arteriosclerosis) and employment at hard labor are considered important etiologic factors in the production of chronic degenerative arthritis.
5. The focal degenerative arthritis found at necropsy in young adults offers the gross pathologist, in my opinion, some additional presumptive evidence of syphilis, and the application of the laboratory tests for the disease is indicated.

MYOSITIS PURULENTA ACUTA CAUSED BY BACILLUS TYPHOSUS

REPORT OF A CASE *

MASANAKA TERADA, M.D.
TOKYŌ, JAPAN

The pyogenic property of the typhoid bacillus was long a topic of discussion by medical writers. At present, as the result of satisfactory evidence, many authors agree that the typhoid bacillus can cause the formation of pus in various organs, although cases of typhoid followed by myositis purulenta acuta caused by the typhoid bacillus are very rare. Lately I have observed a case of myositis purulenta acuta of the upper arm caused by the typhoid bacillus during the course of typhoid fever.

REPORT OF CASE

History.—A man, aged 34, who had enjoyed good health, was suddenly taken ill with chills and fever, the temperature reaching 40.2 C. (104.3 F.) at onset. The lips were dry and the tongue was coated with a thick white fur; the appetite was poor; there was retraction of the abdominal wall, but no tenderness. At first there was slight diarrhea, but later, constipation. The spleen became enlarged, and its edge was distinctly felt below the costal margin. In the liver and the kidney no changes were clinically noted. The pulse was strong and regular, ranging 100 or more, and the heart sounds were normal. There were no changes of the respiratory organs throughout the entire course save for the occurrence of epistaxis two or three times. There were no serious nervous manifestations at the beginning, but only persisting headache and slight pain in the lumbar region. Toward the end of the disease the patient was delirious. There were no changes in the kidney. The urine was almost transparent, weakly alkaline, with a specific gravity of 1.010 and no sugar or precipitate, but with a trace of protein. The diazoreaction was positive. Microscopically there were no abnormal constituents except a few leukocytes. There were no changes in the testicle, epididymis or prostatic gland.

A few days after the onset, the characteristic rose-red rashes appeared. Two weeks later the patient began to complain of pain in both the upper arms. This attack of pain was accompanied by chills and high fever, and a reddish swelling appeared on the postero-external side of the right upper arm, extending from the elbow to the lower margin of the deltoid muscle. Petechiae were present, but a thickened periosteum was not palpable. The symptoms of the left upper arm diminished in severity. A deep incision was made in the upper third of the right arm, and a small quantity of seropurulent fluid was evacuated. Later a few blebs formed around the incision.

Bacteriologic Examination.—A few drops of the patient's blood were cultivated in bile broth and ordinary broth; both mediums showed uniform cloudiness. The growth, when cultivated on various mediums, showed the following characteristics:

Agar: After incubation for twenty-four hours at 37 C. (98.6 F.), small, circular, thin, bluish-gray, transparent colonies were seen which remained always thin.

Gelatin: All the colonies presented a characteristic appearance. After incubation at 37 C. for twenty-four hours, small, round colonies, always thin and transparent, appeared. The edge of each colony became indented and sinuous, and at the same time ridges extended from them into the center, which became thicker than the margins. The colonies developing in the depth of the gelatin and sometimes even those on the surface had quite a different appearance. They were round and opaque, and were about the size of a pinhead.

Stab Culture: After incubation for twenty-four hours at 37 C., along the line of the stab, small, round, yellowish-white and confluent colonies appeared, while on the surface there were thin, transparent and widespread confluent colonies.

---

[4] Russell, F. F.: Summary and Discussion of the Work Performed in the Board of Health Laboratory During the Year 1916, Proc. Med. Assn. Isth. Canal Zone, **10**, Part 1.

* From the microbiologic department of the Tokyo Charity Hospital-Medical College.

Milk: The bacillus grew abundantly without coagulating the milk.

Broth and Peptone Medium: The growth in these mediums showed a slight cloudiness, but gradually became more marked, and later the growth became flocculent and ultimately formed an abundant sediment at the bottom of the tube. There was no indol reaction in these mediums.

Litmus-Whey: The fluid remained transparent and reddish-purple, and the bacillus produced no acid.

Glucose-Agar: There was no production of gas.

Potato: At first sight there appeared to be no growth at all, but examination of the surface revealed a slightly moist and very thin deposit.

Morphologically, the bacillus cultivated on agar was as a rule very motile, easily stained with the basic anilin dyes, gram-negative, and rod shaped.

Immunologic Examination.—The bacillus was agglutinated markedly by typhoid-immune serum. Bacteriologic examination of the feces many times ended in negative results. Negative Widal reactions were obtained nine and fourteen days after the onset of the disease. From the fluid that flowed from the operative wound and from the blebs around the wound, a bacillus was cultivated whose properties were ascertained to be identical with those of the bacillus from the blood of the patient.

Postmortem Examination.—Local Changes: The operative wound of the right upper arm presented the appearance of myositis purulenta acuta, and on pressure a small quantity of grayish fluid flowed out.

Changes in the Intestine: In the lower part of the ileum, corresponding to Peyer's patches, were round or oval ulcers of various sizes. Their borders were as a rule undermined, and sometimes their surfaces appeared dark red. Large ulcers were seen, especially in the lower part of the cecum. The large intestine was filled with an enormous quantity of clotting, and its mucous membrane was a pale brownish gray. The spleen, the liver, the heart, the kidney and other organs also were undergoing acute degenerative changes.

COMMENT

The bacteriologic and pathologic findings justify the conclusion that the case was one of typhoid followed by myositis purulenta acuta. The onset was marked by chills and high fever. The temperature gradually fell, and in a week after the onset became normal. Soon afterward the temperature rose, and was accompanied by myositis purulenta acuta as a partial symptom of the general bacteremia.

Sanatorium Food Monotony.—The importance of nourishing food in sufficient quantities is no greater than the importance of having it pleasing and acceptable to the patient. This is recognized by the relatives, friends and well-wishers of the patient. But unfortunately in many sanatoriums attention is given only to the nutritive aspect of the food and its quantity, while a sad indifference is manifested to its no less important psychological aspects. In the patient's humble home, every effort is made—and properly—to cater to his appetite. The well sacrifice their own comfort in order to further the assimilative forces of the sick by attending to the psychic signaling of the stomach. In the sanatorium it is argued that individual attention in these matters cannot be given. Ergo, a nauseating monotony is introduced in the form of a weekly menu as unalterable as the laws of the Medes and Persians. The guaranteed stability of this dietetic order enables every patient to anticipate with apprehension and loss of appetite the exact arrival of the dish that to him happens to be intolerable. Moreover, the anticipatory distaste irradiates over other food in the same meal which would otherwise be agreeable. Thus the patient is deprived of a most important adjunct to his cure.—Samuel Wolman, M.D., *The Survey.*

Clinical Notes, Suggestions, and New Instruments

AN IMPROVED MODIFICATION OF THE DURHAM FERMENTATION TUBE

K. D. Graves, M.D., Richmond, Va.

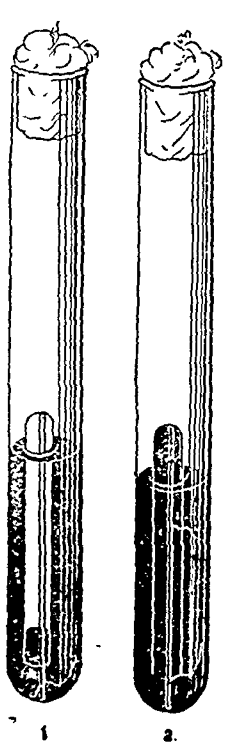
Owing to the fact that certain germs, notably the *Bacillus coli,* have specific action on lactose, breaking it up with the formation of gas when they come in contact with it in culture mediums, it has been the custom for a number of years to use a culture medium having lactose as one of its constituents as a means of testing germs for their sugar-breaking property. A number of containers for the culture mediums have been used, the first of which Smith[1] described in 1889. This bears his name, and has been the one most generally in use until the last few years.

In 1899, Hill[2] suggested a modification of Smith's tube, which consisted of a tightly fitting ground glass stopper with which to close the long arm.

Both Smith's and Hill's tubes, however, were expensive, bulky and hard to clean; hence, when Durham,[3] in 1900, described his tube, which consisted of an ordinary test tube with a smaller tube inverted inside of it, it was considered a distinct step forward.

Durham's tube, which seemed to give satisfaction, has come into general use, and is now considered equally as efficient as the Smith tube. Recently, by a large series of experiments and comparative tests, Lee and Fegely[4] have concluded that "from the standpoint of total efficiency, the Durham tube seems to be the superior of the Smith tube."

In 1914, Hall[5] showed, by a comparative table of results, the value of having a beveled or diagonal edge, instead of a square one, on the inner tube. As Hall pointed out, one objection to the Hall tube is the fact that it is impossible to determine the quality of gas formed in this tube; but this is not really important, since it is simply the presence of gas-forming bacteria that is of interest in the presumptive test for colon bacilli. The chief objection to both the Hall and the Durham tubes is that with them it is difficult to shake up the mediums sufficiently to get the germs into the inner tube in a specimen which is not heavily infected. By running duplicates, inoculated with *B. coli,* I have found that by shaking samples thoroughly several times a day, I would frequently get gas formation in tubes whose unshaken duplicates would not show gas until several hours later; and on comparing the shaken and unshaken tubes, a larger percentage of gas in the shaken tubes was usually obtained than in the unshaken ones.



Tube 1, inner test tube in position inverted over a wooden rod; Tube 2, after being heated in the autoclave, the inverted tube becomes filled with the medium.

These results caused me to feel that probably in making presumptive test of water samples for *B. coli,* this organism was present in a number of cases in such small amount that the germs did not multiply in sufficient numbers to inoculate the inner tube during the time allowed for incubation. The causes which could produce a negative report on a sample of water which had gas-forming bacteria present seem to me to be: (1) The germs might be purely aerobic; (2) the sample of water might have a tendency to stratify near the top of the tube, since it is of a lower specific gravity and does not mix

---

1. Smith, Theobald: Centralbl. f. Bakteriol., 1890, 7, 502.
2. Hill, H. W.: Jour. Boston Soc. Med. Sc., 1899, 3, 137.
3. Durham: Jour. Exper. Med., 1900-1901, 5, 353.
4. Lee, R. E., and Fegely, W. H.: Am. Jour. Pub. Health, 1914, 4, 999.
5. Hall, I. W.: Am. Jour. Pub. Health, 1914, 4, 1173.

freely with the bile medium, and (3) the live germs might be held near the surface of the medium by surface tension.

Taking these facts into consideration, I have devised a tube which overcomes the principal objection to the Durham tube. With this tube it is comparatively easy for bacteria to pass into the inner tube; it is scarcely any more difficult to make and to clean than is the Durham tube, and it is no more bulky.

Technic.—Into a test tube, about 20 mm. in diameter and 250 mm. long, is tubed about 20 c.c. of the medium to be used. (1 per cent. lactose-peptone bile, or lactose-peptone broth). Into this is dropped a tube, 30 mm. long and about 5 mm. in diameter which is inverted over a wooden rod, 50 mm. long and about 2 mm. in diameter. Wooden swab applicators will answer this purpose (Tube 1). The test tube is then slanted to an angle of about 45 degrees and heated to 15 pounds' pressure in the autoclave for half an hour; the escape valve to the autoclave is left slightly open, so that the air which was in the inverted tube escapes as the medium heats up, and its place is taken by vapor from the medium; and later, after the heat is cut off and the medium cools, the vapor condenses, and the inner tube becomes filled with the medium (Tube 2).

I have used these tubes in the laboratory of the Richmond Health Department for the past six months, running them in duplicate with the regular Durham tubes, and they have proved themselves eminently satisfactory.

ADVANTAGES

The use of this tube offers the following advantages:

1. The mouth of the inverted tube is lifted some distance from the bottom of the test tube, allowing free circulation of the mediums in and out of the inverted tube.
2. Shaking is more thoroughly accomplished, since the impact of the inverted tube with the wooden rod causes a sort of churning movement, which draws in and expels the mediums.
3. Raising the mouth of the inverted tube causes a certain amount of gas which is formed between the mouth of the inverted tube and the bottom of the large tube to be caught.
4. The inside tubes are easier to fill, as they are raised from the bottom of the test tube, and a much better egress is offered for the air which they contain.

A DEVICE TO IMMOBILIZE THE HEAD AND EYELIDS DURING OPERATIONS ON THE EYEBALL

E. R. Crossley, M.D., Chicago

Many forms of lid speculum have been devised for controlling the eyelids during operative procedures on the eyeball, most of which depend on the force of a spring of some character to retract the lids. All these devices have their weakness in their frailty and the fact that the patient "can squeeze the eyeball itself" with the lids and actually throw the speculum out of the eye during the operation.

With the ordinary form of speculum, the routine procedure before doing a cataract extraction, after the patient has been placed in position on the table, is to talk to him to get control and his confidence and attempt to exert a hypnotic influence on his mind. If he happens to be a good patient, the surgeon succeeds. If nervous and excitable, as most are, he may roll the head to one side at the critical moment, when the knife is through the anterior chamber, and interfere seriously with the incision or cause the operator to do serious damage to the eye with the knife, if he does not dexterously follow the movement of the head.

The most serious damage may come after the incision is completed and the anterior chamber is open. He may squeeze violently enough to throw out the lens and vitreous through the opening, and lose the eye entirely. Then the patient is told that it was his own fault, for he squeezed. This is not a true statement, for the act is largely involuntary on his part, and we as operators, knowing it to be such, are responsible and should take some positive means to control the patient so that such mishaps are impossible. Undoubtedly, this common accident has occurred to all who are doing an extensive amount of this kind of work.

In the presentation of this appliance for the immobilization of the head and eyelids during operations on the eyeball, I offer a mechanical device that takes complete control of the head and eyelids more effectively and efficiently than a trained assistant can possibly do.

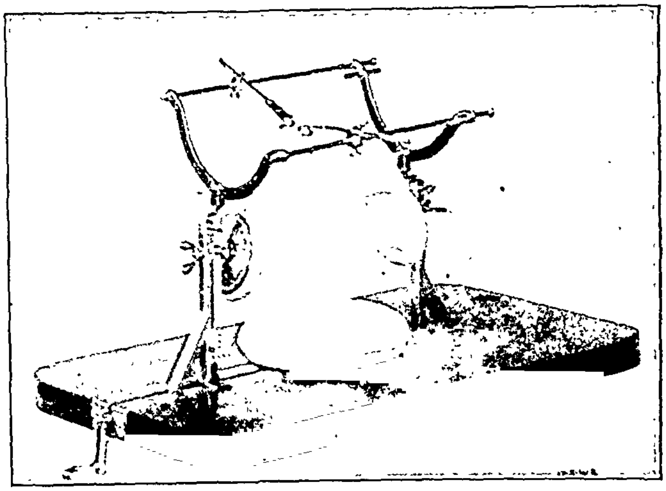


Fig. 1.—Apparatus for immobilization of the head and the eyelids.

With this head clamp and eyelid retractor, the operator can go to his operation with a feeling that no accident is going to occur to detract from his good results, and that he can positively assure his patient that he cannot move and injure himself during the operation.

This reassures his mind and inspires confidence in the operator, obtaining a perfect control of the situation that is impossible to obtain otherwise.

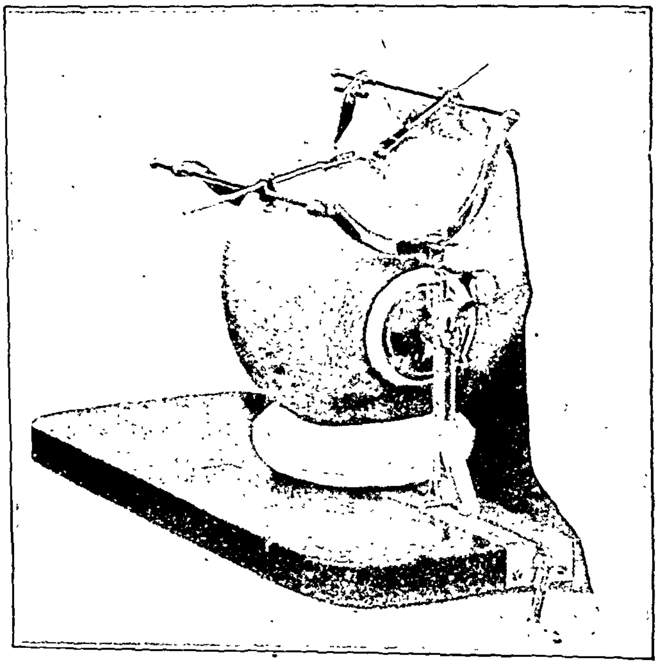

Fig. 2.—Patient with head and eyelids fixed ready for operation.

The apparatus consists of two parts, the base and superstructure or framework carrying the lid hooks.

The base consists of a rectangular wooden block 12 by 22 inches, lengthwise through which is a long screw on which are mounted two strong metal uprights, one of which is stationary, and the other movable. Attached to these are large pads, which grasp the sides of the head as the one approaches the other. The superstructure is a metallic frame which attaches easily to the uprights. On the crossbars of this structure are mounted two sliding locks, for fixing the lid hooks after the lids have been retracted.

Figure 1 shows the apparatus fully set up. Between the two uprights is placed a circular pad which serves as a comfortable head rest. The length of the base is 22 inches, the average width of surgical tables. By means of clamps, the apparatus is fixed firmly to the table on which the patient lies.

Figure 2 shows the patient on the table with the head and the eyelids fixed ready for operation.

In this illustration it will be noticed that the lids are retracted away from the eyeballs, preventing any possibility of squeezing.

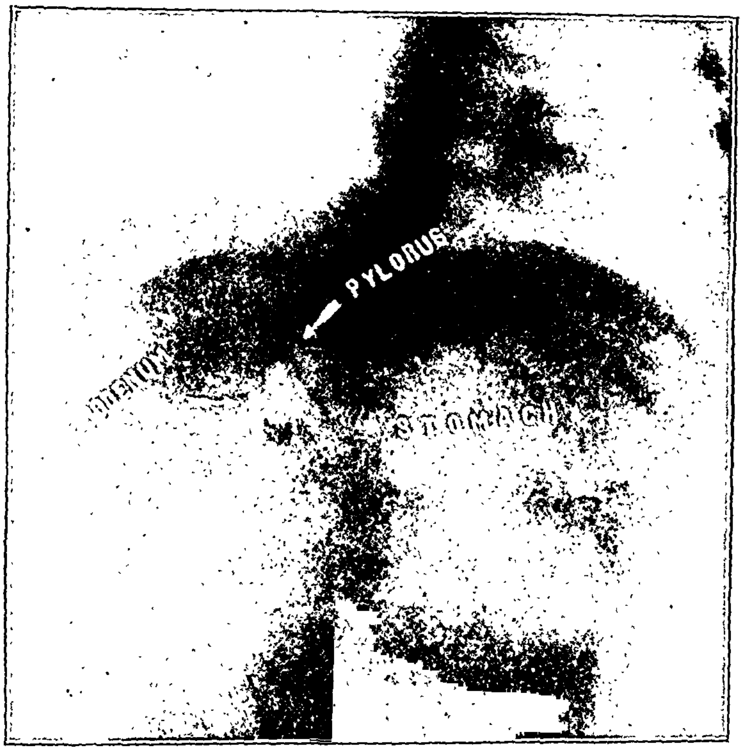
OPEN SAFETY PIN IN AN INFANT'S STOMACH AND DUODENUM

C. Winfield Perkins, M.D., New York

A mother, after a temporary absence, entering the room of her child, aged 14 months, noted that the youngster was swallowing with difficulty. These symptoms terminated in a short time. The mother, naturally becoming suspicious, examined the child's clothing, and where there had been two safety pins, only one was in evidence. A physician was then consulted, and a careful watch for symptoms with a daily examination of the stools was made, without any results. The child all the time seemed perfectly well, showing no symptoms of discomfort whatsoever. A week passed, and the little patient was referred by Dr. J. P. Seward for roentgen examination.



Position of safety pin two weeks after the accident. Stomach distended. The duodenum is indicated by the white dotted line.

Fluoroscopic and roentgenographic examination visualized and open safety pin lodged in the pyloric region. It was decided to wait a while longer with the hope that the pin might pass, as the child continued in good physical condition. The second roentgenogram, a week later, showed the pin located in the same position, associated with a distended stomach and the beginning of some gastric distress, for the child was now continually sleeping on the abdomen. Operation was now decided on, and Dr. W. G. Crump of New York removed the open safety pin, the location and position of which were of exceptional interest, the bar of the safety catch having passed the pylorus into the duodenum, while the sharp end of the pin was embedded in the gastric mucous membrane of the pyloric region, thereby assuming the anatomic angle between the pylorus and the first portion of the duodenum. It can readily be seen that the passage of the pin under such circumstances would be practically impossible.

The child recovered without incident after the operation.

A TUBE FOR BLADDER DRAINAGE IN THE FIRST STAGE OF SUPRAPUBIC PROSTATECTOMY

Edgar G. Ballenger, M.D., and Omar F. Elder, M.D., Atlanta, Ga.

As a rule the major portion of the time required for the preliminary bladder drainage in a two-stage prostatectomy is taken in securing a snug-fitting purse-string suture around the tube.

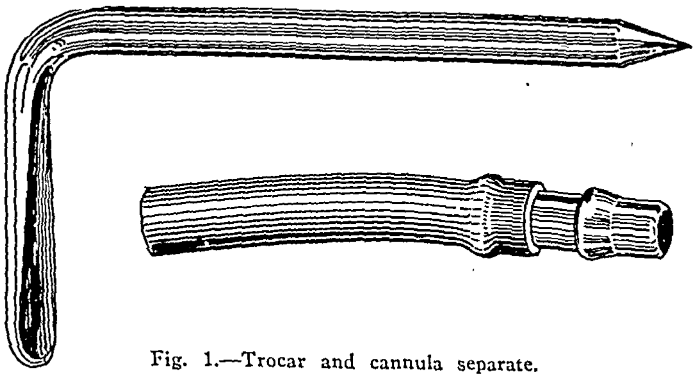

Fig. 1.—Trocar and cannula separate.

To shorten this time and to facilitate the procedure, we have devised a trocar-drainage tube, which is carried through the bladder wall by means of a pointed obturator, which is then taken out, leaving in place the drainage tube, which is connected to a rubber tube, and the urine allowed to flow out.

No suturing of the bladder wall is required, as the tissues composing it are merely pressed apart and it fits snugly around the tube, which cannot slip out of the bladder because of a shoulder on the part of the tube in the bladder. Another shoulder on the outer part of the tube prevents its slipping into the bladder. The obturator is sharpened in a rounded manner and therefore has no cutting edges.

The skin incision, which has been made in the usual manner, is closed with two or three silkworm-gut sutures. The usual care, of course, should be taken to have the bladder distended and the peritoneum pushed well up out of the way. The operation can always be done under gas-oxygen anesthesia or novocain, as it is not necessary to have the muscular relaxation that is required for a purse-string suture.

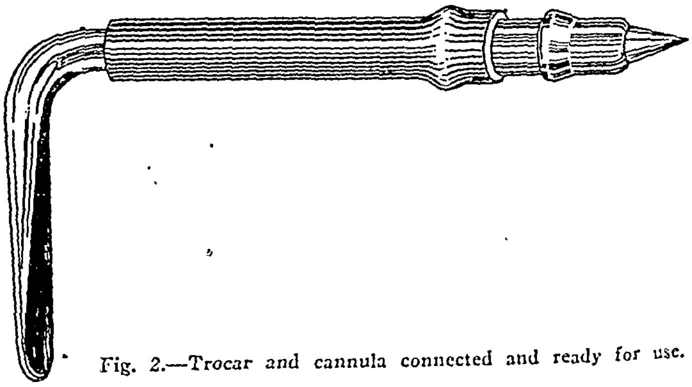

Fig. 2.—Trocar and cannula connected and ready for use.

The advantages, therefore, of such a tube are a shorter time for the operation, a milder anesthesia, and an opening in the bladder which fits the tube so closely that no leakage of urine occurs.

As can be seen from the illustrations, a rubber tube is firmly connected to the outer end of the metal tube. This permits an easy connection to the tube leading to the bottle into which the urine drains. The caliber of the tubes we have employed is one-half inch.

A CARDIOSPASM DILATOR

J. W. Larimore, M.D., St. Louis

The cardiospasm dilator described here was developed to meet certain exigencies in the treatment of cardiospasm cases. It was made by using an ordinary stomach tube of small diameter and attaching to its end the tapering tip of a small bougie. A rubber balloon was then fastened about the tube and bougie end, as shown. About this was placed a bag made of very light weight silk, and so cut that when the first or inner balloon was inflated, there would appear a constriction about the middle. A second balloon was fastened over this. Air-tight fastening of the ends of the balloons was made with rubber cement and winding with small silk thread. This constitutes the dilator proper. Another small balloon may be added inside the first large balloon at its proximal end (Figs. 1 and 2*B*). This balloon is also covered by a silk bag which limits its degree of inflation. Its tube for inflation may extend, as is shown, *through the lumen of the* stomach tube. By a three-way stopcock on the proximal end of the apparatus, either the small balloon or the large outer balloons may be inflated. The small balloon is used by inflating it primarily for locating the instrument definitely within the constriction. It may or may not be used, as circumstances demand.

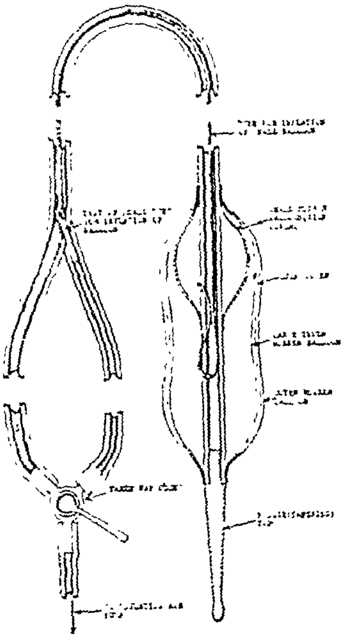

Fig. 1.—Construction of cardiospasm dilator.

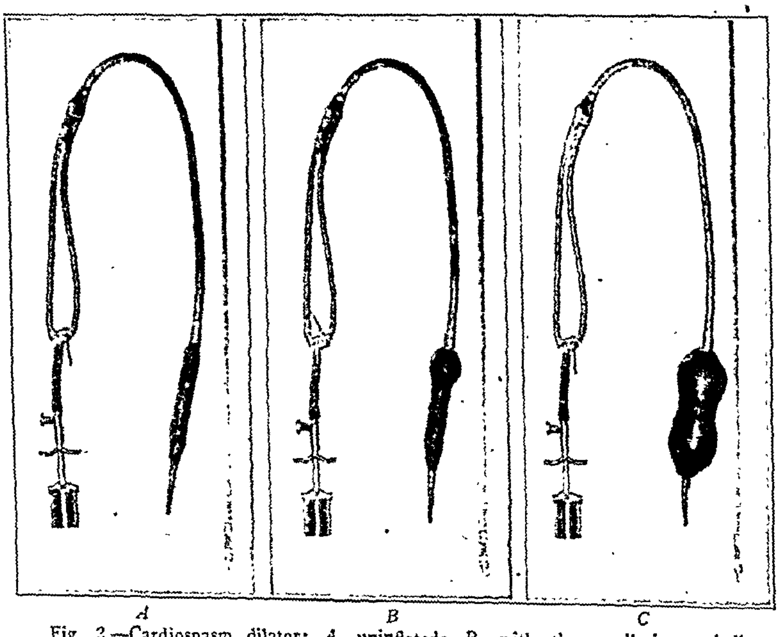

Fig. 2.—Cardiospasm dilator: *A*, uninflated; *B*, with the small inner balloon inflated; when this is introduced to the constriction, the large balloon is properly placed within the spasm; *C*, with the three walled dilating balloon fully inflated.

Air inflation has been found most satisfactory, and is accomplished by the pump from a blood-pressure apparatus. The instrument is shown in the illustrations, and its dimensions may be determined from the accompanying measure.

It has been found that a manometer need not be used, and that the expression of pain by the patient is an adequate and sure guide. The number of strokes of the pump necessary to secure inflation to a moderate or high pressure may be previously determined, and with this knowledge the extent of dilatation during treatment may be readily estimated by counting the strokes which are sufficient to produce pain reaction.

A mandarin is unnecessary for the introduction of the instrument. The tapered bougie tip makes unnecessary preliminary dilatation with bougies. The construction of the inflation balloons allows the instrument to establish itself at the constriction level without slipping above into the sac or below into the stomach.

PELLAGRA IN CHILE

Howard K. Tuttle, M.D., Coquimbo, Chile, South America

I believe that this case of pellagra is the first to appear in Chile.

History.—A white girl, aged 11 years, was brought to our company dispensary for treatment. The other members of the family, including three sisters and two brothers, were in good health. The patient first noticed that the skin on the backs of the hands was becoming red, and that the redness was gradually extending up the forearm, being accompanied by considerable burning and itching. Later the disease appeared on the face, forehead and sides of the neck; the tongue was swollen and sore, and the mouth hot and dry. There were pain in the epigastrium, intense thirst and severe attacks of vomiting. Diarrhea accompanied by cramplike pains in the lower abdomen had been present for some time. Nervous symptoms, such as headache, dizziness, choking sensations, tenderness over the spine, or mild convulsions, also disturbed the patient.

Physical Examination.—The skin over the backs of the hands, forearms, face, forehead and sides of the neck was covered with a reddish-brown, scaling, thickened epithelium. On the hands and arms the scaling was very marked, and extended from the base of the nails to within about 3 inches of the elbow, ending in a distinct outline at the dress sleeve. The mucous membrane of the tongue was swollen, reddened and thickened, but smooth, except for a few deep fissures. The patient had a sad, forlorn facial expression. There was some tremor, and a slow, unsteady gait, showing marked weakness. Palpation revealed severe pain over the epigastrium and dorsal spine.

Treatment and Course.—All corn, cornmeal, rice and dried vegetables were prohibited, and meats, fish, eggs, fruits and milk substituted. Arsenic and dilute hydrochloric acid in proper doses were given internally, and an ointment composed of oil of cade, zinc oxid and petrolatum was applied. Under this treatment the dermatitis showed considerable improvement, especially on the face. This treatment had been instituted during the winter months, but when spring returned, the child was again living in the careless condition of poverty and indifference. The disease began to make rapid progress, resulting in extreme emaciation, anemia, mild dementia and death.

COMMENT

This case presented symptoms so distinct that they could hardly have been mistaken. It is of particular interest, since it serves to illustrate the wide distribution of pellagra, and it is probably the first case reported from Chile.

Disease Defined.—Disease is that condition of an individual in which there is, apart from the normal changes due to age, an alteration of the structures or functions or sensations usually found in the average man of any particular race.—Prof. Ernest S. Reynolds, Bradshaw Lecture.

SYMMETRICAL OSTEOMYELITIS FOLLOWED BY COMPLETE REGENERATION

George Blackburne, M.D., Newark, N. J.
Assistant Attending Surgeon, St. Michael's Hospital; Assistant Attending Gynecologist, Newark City Hospital

M. R., white girl, aged 12 years, was referred to me in December, 1914, with the following history: Five months before, the ends of both thumbs had become swollen and painful. A pustule appeared on the ball of each thumb. These pustules were incised by the patient's physician, evacuated and dressed at intervals for this period. Amputation of the terminal phalanges was suggested, but was refused by the family, who at about this time moved to Newark and brought the child to me.

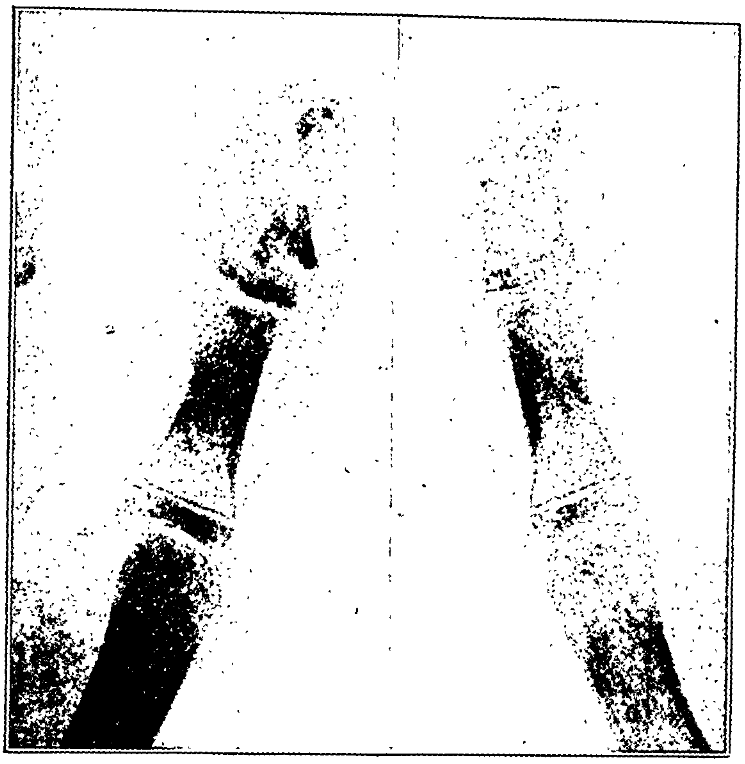

Fig. 1.—Condition of thumbs, Dec. 28, 1914.

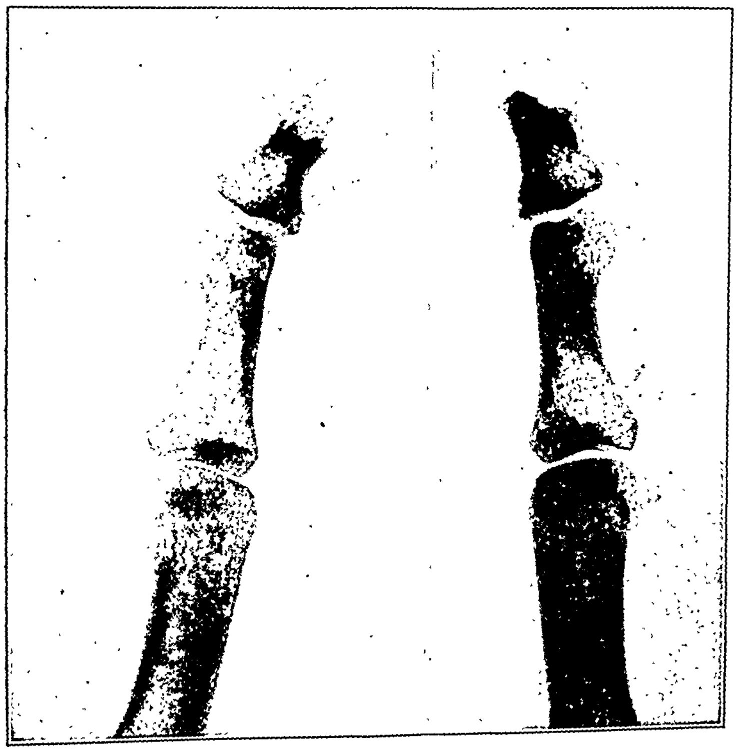

Fig. 2.—Regeneration of phalanges, January, 1917.

Examination revealed a sinus on the ball of each thumb, and loose bone could be detected on probing. A roentgenogram taken by Dr. C. F. Baker, Dec. 28, 1914, revealed complete destruction of the terminal phalanges of each thumb, extending to the epiphyseal line. There were loose sequestra, in each case, as shown in Figure 1. Under local anesthesia, the sinuses were enlarged and the sequestra removed. This was followed by healing in about three weeks.

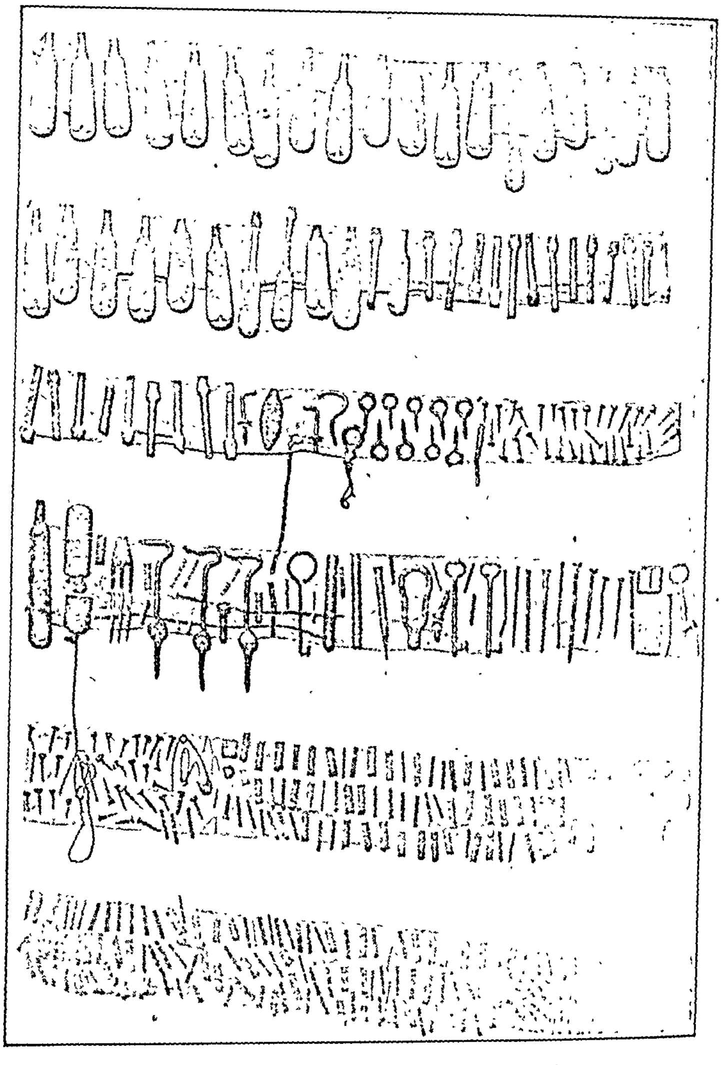
No further attention was given the patient until January, 1917, about two years later, when on examination bone had apparently reformed, and a second roentgenogram (Fig. 2) was taken, showing complete regeneration of the phalanges.

This case seems of particular interest, both from the standpoint of etiology (probably neurologic) and from the end-result.

A CASE ILLUSTRATING FOREIGN BODIES IN THE STOMACH

E. L. Eliason, M.D., Philadelphia

The patient was operated on in Dr. J. B. Carnett's service at the Philadelphia General Hospital. He was referred from the men's nervous ward for operation for acute empyema of the gallbladder. At operation this condition was found, with 213 gallstones. In addition, 452 foreign bodies weighing 3 pounds were removed from the stomach. The patient made a good recovery.



Foreign bodies removed from the stomach.

REPORT OF CASE

J. S., man, admitted, June 16, 1917, to the neurologic service of Dr. Charles Potts in a rather pronounced state of melancholia, had a chill, July 4, and his temperature rose to 105 F. Physical examination revealed a rigid abdomen with marked tenderness and rigidity over the upper right rectus muscle. The leukocytic count was 11,800.

When the patient was transferred to the surgical ward the following day, the temperature had fallen to 100, and the rigidity was less. A few days later, because of a return of the symptoms, a further examination of the abdomen was made. Rigidity and tenderness were again found over the gallbladder. In addition a mass was found with an irregular outline filling the right loin and extending across the abdomen and merging above with the liver. The mass on palpation was found to be movable, and gave the impression of a bag of stones. Dr. R. G. Torrey of the medical service reported the same findings, and further stated that the mass seemed distinct from the liver, but that it could not be clearly outlined on account of muscle rigidity. A hypernephroma of the right kidney was thought of, as was also a retroperitoneal neoplasm. The patient had vomited a rusty brown fluid, which was examined for blood and found negative. No roentgenogram was taken.

July 16, I operated through a modified Martin J-shaped incision. The gallbladder was found enormously distended, greatly infiltrated, and covered with organizing lymph. The duodenum, colon and omentum were closely adherent to it. Filling the entire upper abdomen was a greatly hypertrophied stomach, filled with foreign bodies. The stomach was opened and found to be filled with 452 bodies consisting of nails, pins, tacks, spoons, hooks, glass, forks, etc., as shown in the illustration. The printers' type was wedged so tightly in the pyloric end of the stomach that it had to be picked apart by the finger before it would come loose. The stomach was emptied and closed by a triple tier suture. The gallbladder was next removed and found to be gangrenous and filled with pus and stones.

The patient was drained and returned to the ward. The postoperative course was rather stormy for forty-eight hours, but the patient then improved rapidly. On the third day the patient tried to remove the safety pin from his drainage tube and swallow it.

August 10, the bile drainage had stopped and the wound was almost entirely healed. Roentgenoscopy revealed no foreign bodies in the gastro-intestinal tract. The patient stated that he swallowed the first foreign body just three weeks before operation.

August 14, the patient was out of bed.

August 23, the patient was surgically ready for discharge.

320 South Sixteenth Street.

THE USE OF CALCIUM CHLORID TO PRESERVE MOISTURE IN ANATOMIC SPECIMENS AND CADAVERS

William F. Hemler, M.D., Washington, D. C.
Assistant Professor of Anatomy, Georgetown University School of Medicine

On account of the high price of glycerin, we began to experiment, about a year ago in the laboratories of Georgetown University School of Medicine, to obtain if possible some other substance to keep anatomic specimens moist. As a result, we have adopted for this purpose purified calcium chlorid.

Brain specimens were first hardened in a 5 to 10 per cent. solution of formaldehyd, for about two months, and then transferred to the saturated solution of calcium chlorid, in which they remained for one week. They were then placed on ordinary dissecting room trays, without any cover, except another tray inverted to keep out the dust, but in no solution whatsoever and without even a damp cloth covering to retain moisture.

These specimens have now been kept in this manner for periods ranging from one to nine months, at ordinary room temperature and during the hot months of a Washington summer.

The specimens are perfectly moist and well preserved, and in these trays are readily accessible for study by the students. The gray and the white matter are to be distinguished better than in fresh brains.

By putting about 2 pounds in the embalming fluid for each cadaver, we have apparently been successful also in keeping them moist during dissection.

1330 East Capitol Street.

Military Medicine and Surgery

TENDON OPERATIONS FOR GUNSHOT INJURIES OF THE HAND

LEO MAYER, A.M., M.D.
NEW YORK

In a recent series of articles[1] I outlined the principles of a new system of tendon transplantations based on the anatomy and physiology of tendons. The essential principle of this system lies in the coordination of each step of the operation with the exact anatomic and physiologic facts, as ascertained by researches on the cadaver, by animal experimentation, and by operations on human beings. Thus, the tension under which the tendon is sutured conforms to the normal tension, a physiologic fact hitherto unknown; the transfer of the tendon from its original bed to the new site follows the laws governing the gliding mechanism of tendons; the implantation of the tendons is such as to assure an anchorage as firm as the normal; even in the postoperative treatment the length of time allowed before exercise is begun is determined by exact experimental data. The results attained by the method, as observed in 250 cases of poliomyelitis and in fifty tendon transfers subsequent to gunshot injuries, justify its employment as a sound surgical procedure.

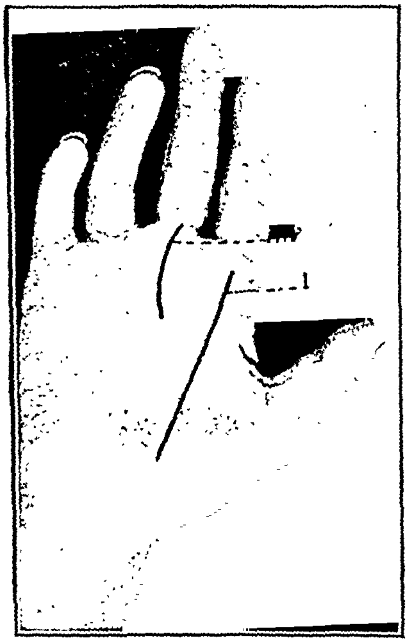


Fig. 1.—The incisions for transplantation of the flexor sublimis tendon of the index finger for the severed flexors of the middle finger: 1, first incision; 2, second incision.

At the present time a double significance attaches to a rational system of tendon operations. First, there is the large group of poliomyelitis cases in which decided improvement of function can be obtained by tendon transplants; secondly, there will unquestionably, provided the war is not brought to an abrupt conclusion, be a large number of patients with gunshot injuries, on whom similar operations can be satisfactorily performed. That this group of patients will probably represent no small percentage of those to be treated in our American base hospitals is shown by my experience during a three years' service as surgeon to a 500 bed Red Cross base hospital near Berlin, where of 1,400 operations, fifty, or almost 4 per cent., were performed on tendons.

The purpose of this paper is to draw attention to several tendon transplantations hitherto not described, which I have found of service in gunshot injuries of the hand. One of the commonest lesions seen in a base hospital is a perforating wound of the hand, the wound of entrance being located on the palmar aspect, and the larger star-shaped wound of exit on the dorsum. Almost always one or more metacarpal bones are fractured, and the flexor and extensor tendons of one or more fingers are completely severed. Such an injury leaves the patient with a badly crippled hand, since one or more fingers are not merely useless but in the way. Despite the usual demand for amputation of the helpless members, it seemed to me advisable to conserve wherever possible, even though a complete restoration of function could not be hoped for. Therefore, in all cases in which the hand was not irretrievably shattered, I attempted to restore function by means of tendon operations for both the flexors and the extensors. These operations cannot be considered in the same category as the physiologic transplantations described in my previous articles, since from the nature of the injury it is impossible to utilize a tendon sheath as a path for the transferred tendon, and since the transferred tendon must be sutured to another tendon instead of being directly attached to the bone. In other respects, however, they conform to the principles of the physiologic method.

---

[1] Mayer, Leo: Surg., Gynec. and Obst., 1916, **22**, 182, 298 and 472.

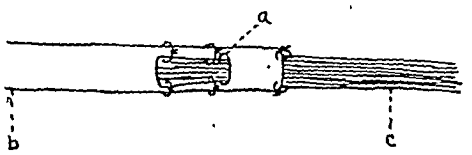

Fig. 2.—Suture of tendon to tendon when overlapping is possible: *a*, button-hole opening; *b*, flexor profundis tendon of the injured finger; *c*, transplanted flexor sublimis tendon.

TECHNIC

The operation for the severed flexor tendons consists in transplanting the sublimis tendon of the adjacent finger and suturing it to the distal end of the injured flexor profundus tendon; that is, two adjacent fingers are thus supplied with the profundus tendons alone, since the one sublimis tendon is converted by the operation into a deep flexor. The steps of the operation, which I always perform under local anesthesia, are as follows:

(For the purpose of illustration I will assume that both flexor tendons of the middle finger have been severed, and that a mass of scar tissue the size of a 50 cent piece occupies the midpalmar region and is densely adherent to the bone.)

The first incision runs from a point 2 inches distal to the annular ligament in a line with the tendons of the index finger to the proximal phalanx of this finger (Fig. 1). The incision is deepened through the palmar fascia, until the sublimis tendon is visible throughout its course.

The second incision is made distal to the scar tissue over the severed flexor tendons of the middle finger; it is about 1½ inches long, slightly bowed, with the convexity toward the little finger, and extends to the base of the middle finger.

The flexor tendons of the middle finger are then dissected free from the adhesions which usually bind them down. The operator must pay particular attention to this step, since adhesive bands frequently extend well into the sheath. When properly freed, gentle traction on the flexor profundus tendon should produce flexion of the finger.

A subcutaneous channel is then bored with a dressing forceps from the proximal end of the first incision to the second incision. This step of the operation is usually rather difficult, owing to the presence of scar tissue. It is better to give the channel a slightly curved direction, since a straight course would necessitate boring between scar tissue and bone; the slight curve tends to be obliterated by the action of the tendon as soon as active motion has begun, whereas boring between scar tissue and bone tends to produce adhesions which nullify the effect of the operation. When a channel sufficiently roomy to accommodate the tendon has been bored, the sublimis tendon of the index finger is divided at the metacarpophalangeal joint, dissected away from the deep tendon, and drawn through the subcutaneous channel as rapidly as possible so as to avoid drying.

The final step of the operation consists in suturing it to the flexor profundus tendon of the third finger. I have applied this suture in two ways. When both tendons are well developed and can be made to overlap for three-fourths of an inch, I make a buttonhole opening in the tendon of the injured finger about a quarter of an inch from its severed end, and thread the sublimis tendon through this opening (Fig. 2); the two tendons are held together by means of from four to six fine interrupted chromic gut sutures so placed as to flatten the tendons against one another. To promote firm fixation of the tendons to another, it is advisable to traumatize slightly the surfaces of the tendons which are brought into apposition.

Another method of tendon suture is indicated if the tendons are friable or cannot be made to overlap. Under these conditions I have found that the first suture method did not give sufficient security. Therefore, after suturing the tendons by means of the Lange stitch (Fig. 3 *A*), I reenforce this suture by transplanting a piece of fascia from the calf. The technic of this procedure when practiced occasions no difficulty. A 3 inch incision is made a hand's breadth above the annular ligament of the ankle and a strip of fascia 2 inches long and 1 inch wide is dissected away from the muscles. Particular care is taken to handle only the corners of the fascia, so as not to injure the loose fatty tissue, which at this point covers the deep surface of the fascia and is of particular importance in facilitating the normal gliding mechan-

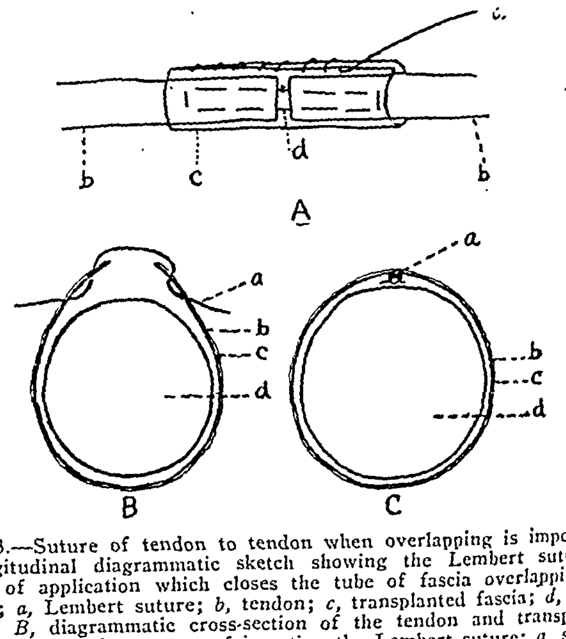

Fig. 3.—Suture of tendon to tendon when overlapping is impossible: *A*, longitudinal diagrammatic sketch showing the Lembert suture in process of application which closes the tube of fascia overlapping the tendons; *a*, Lembert suture; *b*, tendon; *c*, transplanted fascia; *d*, Lange suture. *B*, diagrammatic cross-section of the tendon and transplanted fascia indicating the manner of inserting the Lembert suture; *a*, suture; b, fascia (superficial surface turned toward the tendon); *c*, fascia (deep surface turned outward); *d*, tendon. *C*, diagrammatic cross-section of the tendon and transplanted fascia after the Lembert stitch has been drawn taut. Note that the smooth deep surface of the fascia adapted to the gliding function is turned outward: *a*, suture; *b*, fascia (superficial surface); *c*, fascia (deep surface); *d*, tendon.

ism of the muscles and tendons. At each corner of the fascial flap a suture is taken to permit more ready handling.

The assistant grasps two of these sutures, the operator the other two, and in this way the fascia is transferred from the calf to the hand. The sutured tendons are then lifted out of their bed so as to pass two of these fixation sutures beneath them. By means of a continuous Lembert suture the fascia is made to form a tube closely surrounding the sutured tendons (Fig. 3, *A*, *B* and *C*). The fascia is so placed as to turn its glistening deep surface outward; if the Lembert suture has been properly inserted, the point of union of the two tendons is completely hidden by a smooth strong envelop well adapted to a gliding function.

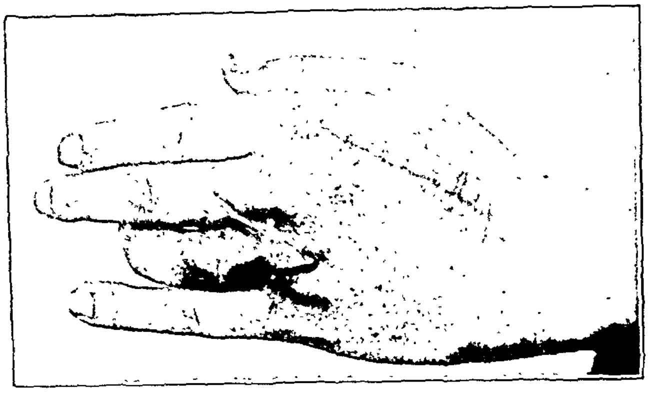

Fig. 4.—The incisions for transplantation of the index finger tendon of the extensor communis digitorum to replace the severed extensor of the ring finger.

The results obtained by either of these tendon sutures are satisfactory. The first method is, of course, the one of choice on account of its simplicity. The operation is concluded by applying continuous skin sutures.

A similar operation can be performed for the divided extensor tendon, provided the tendon of the extensor indicis proprius has not been injured. It consists in transplanting the tendon of the extensor communis digitorum, which runs to the index finger, to replace the injured tendon. The extensor indicis proprius suffices, I have found, to extend the index finger. A 4 inch incision (Fig. 4) lays bare the index finger tendon of the extensor communis digitorum. A second incision over the severed extensor tendon frees it from the scar tissue which usually holds it adherent to the bone. By means of a subcutaneous channel the substituting index tendon is transferred to its new position and sutured to the injured tendon by one of the methods previously described.

In performing the tendon suture the rule governing the normal tension of tendons must be respected. Research studies[2] on animals have shown that when under narcosis the origin of the muscle and the point of insertion of its tendon are approximated, the tension is zero. In other words, in the case of the flexors of the fingers, when the fingers are passively flexed while the muscle is at rest, the tendons of the flexor muscles show no appreciable tension. Consequently, when the operation is being performed, the tendon should be sutured in such a way as to give just this normal degree of tension.

AFTER-TREATMENT

In the after-treatment, the most important question is when to begin active exercise of the transplanted tendon. The animal experiments referred to in my previous articles were of comparatively little assistance in deciding the question, since in them the tendon was attached directly to bone, whereas in these operations the tendon was sutured to tendon. By beginning exercise too soon, one ran the risk of tearing the tendons apart before firm union had taken place. By postponing active exercise too long, one permitted dense adhesions to form. In my first case, I began exercise too soon, namely, one week after the operation. The tendons tore apart, and a secondary operation had to be performed. In the second case, in which I waited three weeks, the final result was disappointing because adhesions prevented a free gliding of the tendon. In subsequent cases, I immobilized the tendons for two weeks before permitting function. The best exercises are the voluntary contractions of the patient's muscles. In some cases, when it was difficult to secure the patient's cooperation, I employed a galvanic current to secure the necessary muscular contraction. As soon as about 20 degrees of motion had been secured, the tendon was strengthened by simple resistance exercises. For at least four weeks following the operation, the fingers and hand should be protected by a splint that holds the operated finger in such a way as to remove all tension from the suture. Failure to observe this rule can prove disastrous, as was shown in the case of one particularly ambitious patient who, contrary to orders, removed the splint while working in the garden two weeks after the operation. He happened to fall on the outstretched finger, and the suture gave way.

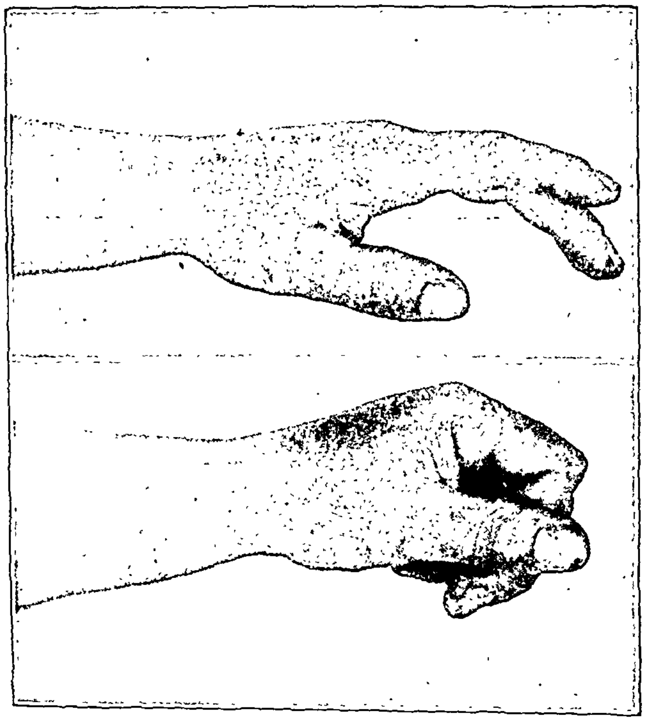

Fig. 5.—The degree of flexion secured by transferring the flexor sublimis tendon of the index finger for the severed flexor tendons of the middle finger; upper, fingers extended; lower, fingers flexed.

The outcome of the operations were satisfactory to my patients although not entirely satisfactory to me. Primary union occurred in all but one case, in spite of

---

2. Mayer, Leo: Surg., Gynec. and Obst., 1916, **22**, 196.

the presence of shell fragments, and extensive scar formation. A complete restoration of function, however, I could not secure. In the most successful cases about 75 per cent. of the normal range of motion returned (Figs. 5 and 6). With this degree of motion my patients were able to use the finger for typewriting, holding pen and pencil, for light farm work, even, as in one case, for playing the piano. As a rule, the operations for the extensor tendon gave better results than that for the flexor. Sacrificing the flexor sublimis tendon produced distinct weakness for six or eight weeks after the operation; practically the normal strength returned when adequate exercise was instituted. The sacrifice of the extensor tendon of the index finger was scarcely noticed by the patients.

As stated before, these tendon operations on the hand are not ideal physiologic procedures. They represent an attempt to improve a desperate condition by a conserving method instead of ruthlessly sacrificing the entire finger. In the eyes of the patient the discomfort of the operation was fully repaid by the partial restoration of function. To the surgeon interested in tendon work these cases should form an incentive to further study, and to the perfection of a technic that will give a more complete restoration of the normal tendon motion than I have been able to secure in this first series of operations.

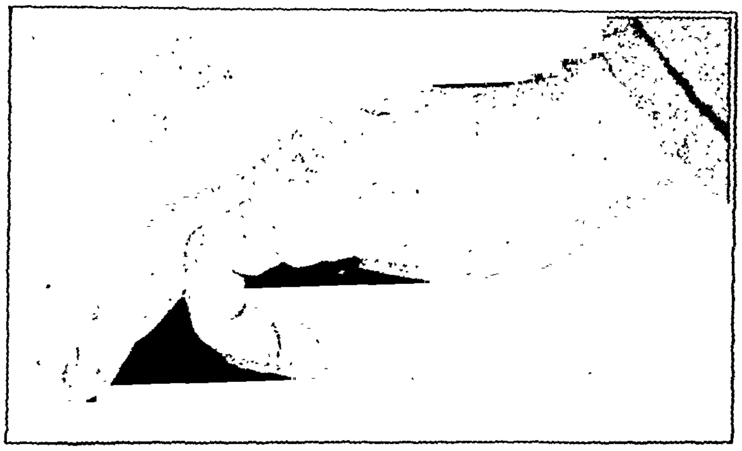

Fig. 6.—The extension made possible by transfer of the extensor tendon of the index finger (extensor communis digitorum) after complete division of the extensors of the ring finger. (The same hand is shown in Figure 4.)

41 West Eighty-Third Street.

War Activities for Antituberculosis Associations.—The National Association for the Study and Prevention of Tuberculosis has made suggestions for a course of action to be followed by state, county and community tuberculosis associations with reference to men drafted for the Army. These suggestions were formulated as the result of conferences with Army officers, public health officials, Y. M. C. A. and other organizations engaged in war work. They have been found practicable in four of the cantonments where action has been taken to carry them out. They include the procuring of a record of men rejected for service in the Army because of tuberculosis or suspected tuberculosis; those rejected by local examining boards, rejected applicants for enlistment in the United States Marine Corps and those rejected by regimental surgeons in the camps and cantonments; follow-up work for all cases discovered, which would include the work of visiting nurses, who should be asked to make a survey of families of rejected conscripts; educational work for soldiers which would include the distribution of pamphlets and folders, lectures and talks in connection with the entertainments provided by the Y. M. C. A., the Knights of Columbus, etc., which would include motion picture reels, medical talks, etc.

CARDIOVASCULAR LESIONS AND TUBERCULOSIS

METHODS AND RESULTS OF EXAMINATIONS BY THE CARDIOVASCULAR AND TUBERCULOSIS COMMISSION AT THE SECOND PLATTSBURG TRAINING CAMP FOR RESERVE OFFICERS

ALBERT P. FRANCINE, M.D., PHILADELPHIA
Captain, M. R. C., U. S. Army
CAMP GORDON, ATLANTA, GA.
J. WOODS PRICE, M.D.
First Lieutenant, M. R. C., U. S. Army
AND
FRANCIS B. TRUDEAU, M.D.
First Lieutenant, C. S., U. S. Army
SARANAC LAKE, N. Y.

On account of the military roster, we were assigned for examination one company a day, averaging 135 men. Each member of the board examined his third of this number, and any men found with signs in heart or lungs deviating from the normal were held up for combined study by the board.

In beginning our work we had no very definite plan to follow, except that our instructions, as to what would disqualify from active service or require a recommendation for special service, were plainly set forth in the very definite and excellent circulars, Nos. 20 (for tuberculosis) and 21 (for cardiovascular conditions) of the War Department, Surgeon-General's Office.

METHODS

The men in each company were assigned to us in groups of ninety in the afternoon, reporting at 1:30 p. m., and the remaining forty or forty-five men next morning, reporting at 10 a. m. The holdups from the previous day, of whom there were usually from five to ten, were reexamined by the board between 8:30 and 10 a. m. daily.

These groups reported to a sergeant in a large locker room and dormitory adjoining the three small examining rooms (bedrooms), and he entered on the form below their name, age, company and regiment. Then each examiner took a group of five men to his room and proceeded with their examination. Each examiner had a medical orderly who acted as clerk and filled in the accompanying form from dictation.

After some experimenting, we finally fixed on the following routine:

1. The five candidates were lined up and their pulses taken, standing and before undressing.

2. Then they stripped to the waist, and each man was inspected for abnormal pulsations, the character and location of the maximum heart impulse was determined, and the boundaries of the heart were outlined by percussion.

3. Then the whole five were made to exercise for about half a minute by marking double time and at the same time driving their arms forward and back, and at the command of "Halt" the examiner went down the line ausculting with care each man's heart. If when he reached a man his heart had already quieted down, he was made to exercise again. But with five men, the amount of exercise indicated was usually sufficient to keep the last man's heart well accelerated by the time he was reached. It was for this reason that we finally fixed on a group of five men and because better order and quiet could be maintained, than with a larger number, and it was also easier for the orderly at the desk.

4. Following the examination of the heart, the examiner proceeded with that of the lungs, confining this to thorough auscultation after cough and on deep inspiration. When any

deviation from the normal was found in heart or lungs, the examiner did not attempt to study the condition thoroughly, but told the man to report at 8:30 next morning for study by the combined board.

5. Each man was told to dress as the examination of his lungs was completed, and his pulse was again recorded before he left the room.

FORM FOR RECORD OF EXAMINATION

Name: Age: Company: Regiment:
Pulse rate, dressed, standing: Abnormal pulsations:
Maximum heart impulse: Thrills:
Cardiac boundaries, left: Right:
Accentuations: Arrhythmias:
Pulse rate, after dressing: After resting, if above 112:
Lungs:

After a little experience, we found that it took about twenty minutes to examine satisfactorily these groups of five men. This allowance of time can, of course, be cut down to twelve or fifteen minutes by not counting fully and not recording the pulse, except in those cases in which it is palpably rapid, or very slow. But we feel that in this work, which is exacting and in which one must remain standing and alert, the faster work is not compatible with the concentration and thoroughness which is its fundamental purpose. It also spoils the interest of the work, and it becomes a mere grind, for the work is interesting if done without rushing, and in the large number of men examined one may expect at any time to come on an interesting lesion, as will appear from the subjoined report. Hence, we do not feel that a man can do this work right, day in and day out, and work more than six hours a day.

At times we did more than this. We had to complete the examination of a company of coast artillery, which had been suddenly ordered away, 180 men in all, in one morning; and then went on with our ninety men in the afternoon, 270 men that day, or ninety men for each examiner. But it would have been impossible to have kept this pace up, nor did we in the case of the artillery men attempt to record the pulses or even to count them, but quickly satisfied ourselves that the rate was not abnormally rapid or the reverse. We think the strain and hurry showed in another way, for whereas we held up, for further study, as a rule, from five to ten men out of every company of 135 or 140 men, out of this battery of 180 men, we held up only two men at the end of the morning's work. Our examination, therefore, was probably not so thorough.

Again, a certain group of seven of the companies could be assigned to us only in the afternoons, so that their examination had to be completed then, averaging forty-five men for each examiner, with no work at all in the mornings. This we found an unsatisfactory arrangement.

From our experience, therefore, we would conclude that a full day for an examiner doing this work in a routine manner and thoroughly would be forty-five men in the afternoon and twenty men in the forenoon. This would not include the holdups, who would report to the board for study before the individual examinations began. In other words, about sixty-five men a day for each examiner and the holdups to be studied by the board is a full day's work. An outside limit would be forty-five men in the afternoon and thirty in the forenoon, or seventy-five new men a day for each examiner.

In regard to the holdups, it is very important that any lesions in the heart and lungs, even though not sufficient to disqualify, be carefully noted and reported to the Surgeon-General, in view of a possible future claim for pension for disability in line of duty.

While the foregoing does not seem numerically a great deal, or the hours very long, yet when one comes to standing on one's feet for six hours and ausculting hearts and lungs continuously day in and day out, and doing it with attentiveness, for one must neither lag nor grow inattentive, it makes a very adequate and even exacting working day.

RECOMMENDATIONS

We feel that:

1. Six hours a day is a full day for this work if done as a routine.

2. The new men should be examined in groups of five by each examiner working separately.

3. It should not take more than twenty nor less than fifteen minutes to complete the examination of these groups of five men for cardiovascular lesions and tuberculosis.

4. Each examiner should examine not less than sixty nor more than seventy-five new men a day.

5. The holdups from the previous day should report next morning for reexamination by the entire board, if the board is a small one, and this should constitute the first work of the day. Of course the holdups from each morning and afternoon period can be reexamined by the board immediately after the individual examinations on the same day. This has the advantage of not requiring the return of the holdups the next morning; it has the disadvantage of the examiners' not being fresh at the end of the afternoon's work, and there is the disadvantage of the candidate's not being fresh, as he is after a night's rest.

6. When the board is a large one, for instance, fifteen or twenty medical officers, the president of the board should select two other members to act with him as a clearing committee to whom all the holdups should be referred for final disposition. This insures uniformity of judgment and good order. The whole time of this committee will be occupied in keeping up with the holdups of the ten or more officers who are doing the routine examinations, and in the clerical work involved. The holdups of the other examiners for each day should report the following day to the clearing committee, divided, if numerous, into two groups, one in the morning and one in the afternoon.

7. The assignment of the men to the examiners should not be confined to company divisions because time is thereby lost all around; but assignment should be made by fixed numerical groups, the guiding factor being the quota stated above for each examiner. Thus three examiners, who are also doing the holdups, should be assigned sixty men in the morning, and 135 men in the afternoon, a total of 195 men, or in round numbers 200 men a day, as the extra five men could readily be added to the morning's quota of sixty. Or if the men must be assigned by companies, then the number of examiners should be adjusted to these numerical groups. In our case, with four examiners working, we could have examined two companies daily, whereas three examiners did not have quite enough to do taking one company a day, and yet could not possibly have taken two, in addition to the holdups. Where the companies number 250 men, four examiners should be assigned for each company, or according to this ratio. Thus, sixteen examiners should complete 1,000 men a day, but this board should total nineteen officers, three for the holdups.

8. There should be out of a group of 200 men, as a rule, from five to fifteen holdups daily (in the class of men in camps for reserve officers) to be studied by the board next morning.

9. The holding up of a man in this way does not in any sense mean his disqualification, and this should be explained

to him, but is simply in order that his condition may be adequately studied, and a detailed report noted for transmission to the Surgeon-General at the final completion of the examinations.

RESULTS

The holdups resolved themselves into two groups, those that had to be written up, and those that could be readily passed. Of the latter the great majority had rapid pulses. There is a wide variation of rate according to the time of day, and the character of the military exercises or drills to which the men have been subjected previous to the examinations. In the morning, the pulses as a rule ran in slow rhythm, or when the men had been doing map making or signal corps work. These averaged between 64 and 74 standing, and between 74 and 84 following the exercise test (after dressing). But in the afternoon, after a hurried or heavy lunch or a morning's hard drill, we found the majority varying between 84 and 100, and many above 100, even 120, before exercise test. The latter offered some difficulty, because even after sitting or lying down while the examiner continued with his work, many of them could with difficulty be counted below 100 (a persistent rate of 100 or above disqualifies). Accordingly, we were forced to send quite a number to the hospital for hourly observation of the pulse before we could let them go. Following this method in the more thorough search for an etiologic factor, we disqualified two candidates (Cases 1 and 3).

There is also to be taken into consideration the factor of nervousness as a cause for rapidity of pulse. Generally speaking, this played a minor rôle with the men we examined, although they were in many instances fearful of the result of the examination on account of their earnest desire to serve. There was very little effect of nervousness noted in the men who came in the morning; and as stated above, there were the other more obvious factors for acceleration of pulse rate in the men who came in the afternoon. Usually, when nervousness was a factor, a little rest brought the pulse down, or it was down when the candidate was reexamined next morning. This was true in every instance but one (Case 16), and this candidate was finally passed for active service in the absence of definite cause.

We discovered also a number of murmurs, systolic in time, in the pulmonary area and in the third and fourth interspaces to the left of the sternum, the area of auscultatory romance of Balfour. There were sixteen out of 3,134 candidates, or 0.51 per cent. These murmurs are striking, and their pathogenesis an interesting academic question; but clinically, in the absence of enlargement of the heart and accentuations, and with good response to the exercise test, they are not of particular significance, though they should be reported. Case 14 is a good example. They are not infrequent in long chested types, but occur also in big, well formed thoraces, and are not uncommon in early adult life.

There were also a number of men who developed after exercise a functional systolic murmur at the apex, transmitted into the axilla. Their hearts were, however, organically normal, and their response to exercise and pulse rate good. These were passed, and numbered fifteen out of 3,134 cases, or 0.47 per cent. Case 12 is an example.

We found also a number of cases in which the maximum impulse of the heart was in the sixth interspace when standing, but frequently in the fifth when recumbent, and inside the nipple line and normal in character, without enlargement of the heart. Of these there were passed for active service, but reported, seventeen out of 3,134 cases, or 0.54 per cent. Case 15 is illustrative.

There was one very interesting case of total bradycardia (Case 17). There was one case of idiopathic dextrocardia; and there were several cases of moderate hypertrophy in athletes, without valvular lesion.

Another large group was temporarily held up on account of "colds" and râles in the chest. Acute bronchitis was quite prevalent, indeed, almost universal in the earlier period of the camp, though not all showed râles. The three members of the commission took an active, resonating and synchronous part in this general infection. The differentiation, however, between bronchitic râles and tuberculosis offers no great difficulty, and a little study cleared up this group of holdups.

There were the usual findings of atelectatic râles at the apexes, and the so-called marginal râles at the bases in front; but in these cases the men were not as a rule even held up, unless the râles were unduly persistent.

In regard to the organic cardiovascular lesions found, and the causes for disqualification, or recommendation for special service, and in regard to the similar regulations as applied to tuberculosis, the report of the individual cases is the best exemplar. We feel that the practitioner of medicine or any one interested in this subject would do well to familiarize himself with circulars of the War Department, Surgeon-General's Office, Nos. 20 and 21, which are brief, explicit and illuminating.

CARDIOVASCULAR DISEASES

TABLE 1.—RESULTS OF CARDIOVASCULAR EXAMINATIONS OF CANDIDATES

	Number	Per Cent.
1. Candidates in reserve officers' training camp examined	3,134	.....
2. Accepted	3,124	99.06
3. Disqualified because of cardiovascular lesions	4	0.127
4. Recommended for special service but allowed to continue course at training camp	4	0.127
5. Passed for active service, but with functional lesions reported	51	1.62
6. Found with cardiovascular (organic) lesions (3 and 4 above)	8	0.255

The following four candidates were disqualified for active service and recommended for discharge:

Case 1.—*Physical Findings.*—S. G. E., aged 23, was remanded to the hospital for study of the pulse rate, where during six days' observation it was with few exceptions persistently above 100, averaging over 120 per minute. There was bilateral enlargement (moderate) of the thyroid, with a fine tremor of the head. There was no marked tremor in the hands or the fingers on extension. The heart was normal in size and there were no murmurs. There was little dyspnea after the exercise test, but the pulse rate was excessively rapid and there was palpitation of the heart.

Diagnosis.—Hyperthyroidism.

The candidate was disqualified for active service.

Case 2.—*Physical Findings.*—G. H. B., aged 36, an artist, could not keep up with the work. Double time caused serious dyspnea and faintness. He could control himself only by sitting down and holding his head between his knees. He had a chronic cough. He was poorly developed and of slight physique. The heart was overacting and very irritable. The pulse was regular but rapid. The heart boundaries were normal. The man developed marked dyspnea after exercise. Breathing was very labored. The facies was anxious.

Diagnosis.—Myocardial insufficiency.

The candidate was disqualified for active service.

Case 3.—*Physical Findings.*—F. L. M., aged 29, was of nervous type. After five days in the hospital the pulse remained persistently over 100, remaining between 88 (once), 112, 128 and 132, most frequently 128. He stated that he stood the work well. The heart apparently was normal. There was no evidence of hyperthyroidism or tuberculosis.

Diagnosis.—Persistent tachycardia.

The candidate was disqualified for active service.

Case 4.—*Physical Findings.*—E. W., aged 47, had an area of definite dulness to the right of the arch in the second and third interspaces, with expansile pulsation, unequal pulses and some arteriosclerosis. There was no tracheal tug. The heart was hypertrophied and dilated, with the left boundary two finger breadths outside the nipple line, with diffuse and heaving impulse. There were no murmurs, but the sounds lacked muscle tone. There was passive congestion of both bases. In the urine, red and white blood cells and albumin were present.

Diagnosis.—Aneurysm of arch; dilatation of heart with failing compensation.

The candidate was disqualified for active service.

The following five candidates were recommended for special service, though it should be understood that as Plattsburg was a training camp for line officers, a recommendation for special service was, as a rule, tantamount to disqualification for active service, to the extent at least that the candidate in question could not, even if he completed his training, receive a commission as a line officer. As a matter of fact, however, there might be occasional demands for special service. For instance, the commanding officer was asked to nominate a small group of men for balloon service in connection with liaison work; and through the kindness of the camp surgeon, Candidate 5 was allowed to take this service. He was extremely anxious to do something, and though at first disqualified for active service, he never left camp.

Case 5.—*Physical Findings.*—M. A. L., aged 35, had been a professional singer and later a musical manager. He was quite fat, and nervous and anemic. The heart was much enlarged to the left, the boundary being two finger breadths outside the nipple line, with the maximum impulse diffuse and heaving. There was no murmur nor accentuations. Response to exercise was poor. He showed considerable dyspnea after the exercise test. The pulse was very rapid. The urine and the Wassermann test were negative.

Diagnosis.—Hypertrophy and dilatation of heart.

The candidate was disqualified for active service and recommended for special service.

Case 6.—*Physical Findings.*—R. P. C., age 30, big chested and of athletic type, had been through the last camp and stood the work excellently. The left boundary of the heart was one finger's breadth outside the nipple line with the impulse under the nipple. It was forcible but not heaving. There was a loud systolic murmur heard at the apex and transmitted to the axilla. There was accentuation of the second aortic sound. The man had had acute articular rheumatism in 1902.

Diagnosis.—Mitral regurgitation.

The candidate was recommended for special service, and allowed to continue training at Plattsburg.

Case 7.—*Physical Findings.*—J. W. M., aged 22, gave a history of an acute heart attack following a 2 mile race from which he was in bed three months with fever and rheumatic pains. This was seven years ago. He was of a big athletic type, and had been a track man at college. There was a loud systolic murmur, heard at the apex and transmitted to the axilla and back. The heart was not enlarged. There was no accentuation of second sounds. Response to exercise and pulse rate was good.

Diagnosis.—Mitral regurgitation without enlargement of heart, and well compensated.

The candidate was recommended for special service, and allowed to complete training at Plattsburg. He was subsequently passed for active service by Major Janeway, and so is not included in figures for candidates recommended for special service.

Case 8.—*Physical Findings.*—L. R. B., aged 26, had a distinct presystolic murmur with a very sharp first sound over the maximum heart impulse, with the right boundary one finger's breadth to the right of the sternum. He had slight dyspnea after the exercise test, but his general condition was good; he was big and powerful, and had played on a varsity football team.

Diagnosis.—Mitral stenosis.

The candidate was recommended for special service, and allowed to complete training at Plattsburg.

Case 9.—*Physical Findings.*—C. A. W., aged 24, had an enlarged heart. The left border was one finger's breadth outside the nipple line. The impulse was under the nipple, forcible but not heaving. There was a systolic murmur in the third interspace to the left, transmitted upward and heard at both the pulmonic and the aortic areas, less at the aortic. Response to exercise was good. The pulse rate was within normal limits.

Diagnosis.—Aortic stenosis.

The candidate was recommended for special service, and allowed to complete training at Plattsburg.

In regard to the candidates showing functional or accidental murmurs, or who showed nonsignificant deviations from the normal, of whom there were fifty-one out of 3,134, or 1.62 per cent., the following case reports are quoted as illustrative. These candidates were all passed for active service following the rulings laid down in Circular 21, War Department, Surgeon-General's Office.

Case 10.—*Physical Findings.*—W. H. G., aged 26, had a malformed chest resulting from a fall from a bicycle in childhood. The heart boundaries were normal, except that the maximum impulse was in the sixth interspace standing, returning to the fifth interspace when prone. There was a soft systolic whiff at the apex, localized to the bell of the stethoscope, heard under all conditions except at full inspiration. There were no accentuations. Response to exercise and pulse rate was normal.

Diagnosis.—Accidental murmur. Motile heart.

The candidate was passed for active service.

Case 11.—*Physical Findings.*—J. W. B., aged 28, had a long chest and a motile heart. The boundaries of the heart were normal, but the maximum impulse was in the sixth interspace, standing, and the fifth interspace, prone. It was normal in character. When the candidate was standing, without exercise, no murmur was heard. After exercise, a fairly loud systolic murmur developed which was heard at the apex, in the axilla and in the back. This was heard also in the third and fourth interspaces to the left of the sternum, both on full inspiration and on expiration. Response to exercise was very good, and the pulse rate was normal.

Diagnosis.—Functional mitral systolic murmur.

The candidate was passed for active service.

Case 12.—*Physical Findings.*—C. S., aged 30, had a systolic murmur at the apex after exercise and transmitted into the axilla. The heart was normal in size. The pulse rate and response to exercise were normal. The murmur was not heard when the man was quiet. There were no accentuations.

Diagnosis.—Functional mitral systolic murmur at apex.

The candidate was passed for active service.

Out of 3,134 candidates, there were fifteen cases, or 0.47 per cent., showing functional systolic murmurs at the apex.

Case 13.—*Physical Findings.*—W. W. C., aged 29, was tall, very thin, flat and long chested, with a marked funnel shaped depression. The heart was normal in size and action. The apex beat was normal and not heaving. There was heard a systolic murmur, loudest in the third and fourth interspaces left of the sternum and in the pulmonary area, but also heard over the aortic cartilage, and also heard very faintly if at all in the vessels of the neck. After the exercise test this murmur became loud and was not altered by posture, and was heard best on full expiration, and faintly on full inspiration. Response to exercise was very good. The pulse rate and the blood pressure were normal, and the urine was negative.

Diagnosis.—Accidental murmur, probably cardiorespiratory.

The candidate was passed for active service.

Case 14.—*Physical Findings.*—W. W. B., aged 25, when quiet heart sounds were apparently normal, as were the boundaries, except that the maximum impulse was in the sixth interspace standing, and the fifth interspace reclining. Following exercise there was heard a systolic murmur best in the third interspace to the left of the sternum, transmitted upward and heard both over the pulmonary and the aortic regions. It was very faintly heard on full inspiration. There was good response to exercise, and the pulse rate was normal.

Diagnosis.—Cardiorespiratory murmur. Motile heart.

The candidate was passed for active service.

Out of 3,134 candidates, there were sixteen, or 0.51 per cent., showing cardiorespiratory murmur.

Case 15.—*Physical Findings.*—G. T. R., aged 22, showed the maximum impulse in the sixth interspace, on standing. It was normal in character. Response to exercise, and the pulse rate were normal. The heart was normal in other respects. The blood pressure was normal.

Diagnosis.—Motile heart (ptosis).

The candidate was passed for active service.

Out of 3,134 candidates, there were seventeen cases, or 0.54 per cent., in which the maximum impulse of the heart was in the sixth interspace, with the heart normal.

Case 16.—*Physical Findings.*—F. H. D., aged 26, was well developed and nourished, but of nervous type. He was in the hospital four days for study of the pulse, which at times was below 100, but was often 120 or above while standing. The pulse leaped rapidly as soon as, or soon after, the radial artery was palpated. The left boundary of the heart was in the nipple line. The maximum impulse was normal in character. No murmur, no exophthalmos and no enlargement of the thyroid were observed. In the fingers extended there was a fine but not exaggerated tremor.

Diagnosis.—Paroxysmal tachycardia, due to nervousness.

The candidate was passed for active service.

Case 17.—*Physical Findings.*—J. O. P., aged 23, had a pulse rate on standing of from 36 to 40, on three separate examinations one week apart. The ventricular impulse was conveyed regularly to the radials. The heart was normal in size; there were no murmurs nor accentuations. After exercise there developed a slight arrhythmia, which consisted in occasional interpolated extrasystoles. There were no pulsations in the veins of the neck, and no evidence of sets of waves in the jugular for each pulse beat. Except for the arrhythmia, there was good response to exercise. The candidate had been an athlete, playing on the Princeton varsity football team four years without being substituted for, and being chosen for the All America eleven. There was no history of syncopal attacks, and he went through the last camp well and was not held up for physical disability. He was big and powerful, and appeared in splendid condition. The urine and the Wassermann test were negative.

Diagnosis.—Total bradycardia.

The candidate was passed for active service.

This interesting case gave the board some concern, because it strongly suggested heart block, and heart block disqualifies. It even disqualifies in the French army, where of course the physical standards for acceptance are reduced to rock bottom. We therefore consulted Major Theodore C. Janeway of the Surgeon-General's staff, under whose supervision the board was acting, and after advice from him and further study of this candidate we felt that his condition was one of total bradycardia and not heart block, and so passed him for active service.

The organic cardiovascular lesions found in the examination of 3,134 candidates were:

Hyperthyroidism, Case 1.
Myocardial insufficiency, Case 2.
Persistent tachycardia, Case 3.
Aneurysm of arch, Case 4.
Hypertrophy and dilatation of heart, Case 5.
Mitral regurgitation, Cases 6 and 7.
Mitral stenosis, Case 8.
Aortic stenosis, Case 9.

The principal accidental or functional conditions found, not disqualifying, were:

Cardiorespiratory murmurs, in sixteen cases, or 0.51 per cent.
Functional systolic apical murmurs in fifteen cases, or 0.47 per cent.
Apex of heart in sixth interspace, increased motility or so-called ptosis of heart, in seventeen cases, or 0.54 per cent.
Many rapid pulses, and one case of apparent paroxysmal tachycardia due to nervousness.
A very interesting case of total bradycardia.
Several hypertrophied hearts in athletes, etc.

It is interesting to compare with the statistical scheme given in Table 1, the corresponding results obtained by the board in examining 584 enlisted men of the Regular Army, who were stationed at Plattsburg Barracks. These included 421 men of the Sixteenth U. S. Field Artillery, ninety-three men of Troop I, Second Cavalry, and seventy men of the Army Medical Corps (Table 2).

TABLE 2.—RESULTS OF CARDIOVASCULAR EXAMINATIONS OF REGULARS

	Number	Per Cent.
Examined	584	......
Accepted	583	99.65
Disqualified for cardiovascular lesions	1	0.17
Recommended for special service	1	0.17
Found with organic cardiovascular lesions	2	0.34

Thus the percentage of organic cardiovascular lesions among the candidates for reserve officers was 0.255, while among the enlisted men of the Regular Army it was 0.34. But, as we shall see later, the percentage of tuberculosis among the regulars was much higher than among the candidates.

TUBERCULOSIS

TABLE 3.—RESULTS OF TUBERCULOSIS EXAMINATIONS OF CANDIDATES

	Number	Per Cent.
1. Candidates in reserve officers' training camp examined	3,134	......
2. Accepted	3,121	99.58
3. Disqualified because of tuberculosis	8	0.255
4. Recommended for special service, but allowed to continue course at training camp	2	0.063
5. Passed for active service but with healed lesion reported	3	0.095
6. Found to be tuberculous	13	0.414

The following eight candidates were disqualified for active service and recommended for discharge:

Case 18.—*Physical Findings.*—W. D. C., aged 22, had many fine râles on cough to the third rib and the fifth vertebral spine on the right. Note was impaired and breathing was bronchovesicular over this area. Roentgenoscopy[1] revealed a definite lesion at the right apex extending to the third rib and fifth vertebral spine, involving the parenchyma and the root of the lung.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was disqualified for active service.

Case 19.—*Physical Findings.*—J. M. W., aged 24, had fine dry râles from the apex to the fourth rib on the left, and about the same on the right, heard posteriorly to the fifth vertebral spine. Roentgenoscopy revealed, *on the right*, scattered parenchymatous infiltration to the second rib and the fifth vertebral spine. Many fibrous strands extended from the root toward the axilla. Through the lower two thirds were a few isolated, scattered tubercles. On the left, scattered through the upper half of the lung, were numerous small, calcified tubercles. These were more conglomerate in the apex, and were characteristic of a parenchymatous infiltration to the second rib and the fifth vertebral spine. Many fibrous strands extended from the root toward the axilla.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was disqualified for active service.

Case 20.—*Physical Findings.*—J. B. G., aged 27, had fine dry râles on cough at the right apex extending to the third rib in front and to the fifth vertebral spine posteriorly, and also a few at the top of the left apex. Note was impaired on the right, and breathing was bronchovesicular. Definite lesion as indicated on the right was confirmed by roentgenoscopy.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was disqualified for active service.

Case 21.—*Physical Findings.*—A. L. B., aged 26, had fine dry râles on cough at the right apex to the second rib and the fifth vertebral spine. Note was impaired and breathing was bronchovesicular. A tuberculous lesion involving this area was confirmed by roentgenoscopy.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was disqualified for active service.

Case 22.—*Physical Findings.*—M. C. L., aged 27, had fine dry râles on cough in left apex to the third rib and the fourth vertebral spine; and in the right apex, above the clavicle. Note was impaired and breathing was bronchovesicular over these areas. Tuberculous infiltration of the areas outlined on both sides was confirmed by roentgenoscopy.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was disqualified for active service.

Case 23.—*Physical Findings.*—E. C. F., aged 30, had fine dry râles on cough at both apexes, with impaired note and bronchovesicular breathing. Râles on the left extended to the third rib, and the fifth vertebral spine; on right, to the second rib and the fourth vertebral spine. Roentgenoscopy confirmed these findings.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was disqualified for active service.

Case 24.—*Physical Findings.*—S. F., aged 36, had fine dry râles at both apexes to the third rib and the sixth vertebral spine. Note was impaired and breathing was bronchovesicular. Roentgenoscopy confirmed tuberculous infiltration in these areas.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was disqualified for active service.

Case 25.—*Physical Findings.*—A. F. B., aged 34, had an area of unresolved pneumonia at the left lower lobe posteriorly, about the size and (apparent) thickness of a man's hand; also a small area of consolidation in the right base posteriorly. Sticky râles, pectoriloquy and bronchial breathing were present over these areas, with friction in the left axilla. Roentgenoscopy confirmed findings, and the complement fixation test was positive for tuberculosis. The Wassermann test was negative. There were no symptoms, and the general condition seemed good. The candidate spoke German and was a reporter on the German front earlier in the war. He was an available man for intelligence service.

Diagnosis.—Unresolved pneumonia due to tuberculosis.

The candidate was disqualified for active service at the Plattsburg training camp, but recommended for special service after cure.

In the following two cases, the candidates were allowed to continue their training at Plattsburg, but were recommended for special service in this country afterward:

Case 26.—*Physical Findings.*—H. B. G., aged 26, had fine râles on cough above the third rib on both sides. Breathing was soft and vesicular. The general condition appeared fine, and there were no symptoms. The candidate was an athlete and competed in running races at the camp the preceding week. Roentgenoscopy revealed: On the right, scattered parenchymatous infiltration to the third rib and the *sixth vertebral spine*, with a questionable area of parenchymatous involvement along the descending trunks; some evidence of fibrosis in the apex; probable pleurisy in the apex, some of which appeared to be interlobar. On the left: scattered parenchymatous infiltration to the third rib and the sixth vertebral spine, with rather much evidence of fibrosis in this region; pleurisy at the base, with diaphragmatic adhesions.

Diagnosis.—Old chronic pulmonary tuberculosis.

The candidate was allowed to continue training, but recommended for special service afterward in this country.

Case 27.—*Physical Findings.*—G. S. C., aged 28, had dry râles and coarse friction at the right apex, and râles below the clavicle to the second rib. Roentgenoscopy revealed a lesion in this area extending to the second rib and involving also the peribronchial area. The candidate was well nourished, and his physical condition was good.

Diagnosis.—Old chronic localized tuberculous lesion.

The candidate was passed for active service at the Plattsburg training camp, but recommended for special service in this country afterward.

---

[1] As facilities for roentgen-ray work were not fully completed at the post hospital, the examinations were gratuitously made at the Adirondack Cottage Sanatorium; Dr. E. R. Baldwin kindly gave us a clinical report on some of the cases.

In the following three cases the candidates were found to have localized and well healed lesions, and were passed for active service.

Case 28.—*Physical Findings.*—W. P. H., aged 28, had a cold, but on two separate examinations (after two weeks), fine dry râles were heard above the left clavicle, breathing soft. He had been an athlete, and appeared wiry and strong. There was no cough nor symptoms.

Diagnosis.—Old localized pulmonary tuberculosis.

The candidate was passed for active service.

Case 29.—*Physical Findings.*—H. R. D., aged 28, had fine râles at the left apex, below and above the clavicle and to the third vertebral spine on the left side. Roentgenoscopy revealed cloudiness of the left apex to the second rib.

Diagnosis.—Old healed tuberculosis lesion, left apex.

The candidate was passed for active service.

Case 30.—*Physical Findings.*—T. C. B., aged 29, had fine small dry râles at the left apex to the second rib, and slight impairment of note. Roentgenoscopy revealed two calcified tubercles and slight cloudiness at the apex. The general condition was good. The candidate was strong and well nourished. There were no symptoms.

Diagnosis.—Old localized tuberculosis.

The candidate was passed for active service.

It may be pointed out in regard to the preceding group of cases that they represent a type not usually seen even by the so-called tuberculosis expert, because the men were to all appearances robust and athletic, for the most part; and practically all were free from any symptoms whatsoever that would draw attention to their condition. Their lesions, as a matter of fact, had been overlooked in previous physical examinations, of which each had passed several, before coming before the board: and it is extremely likely that the ordinary wear and tear of civil life would have failed to light up or activate their infection. The cases were in no sense early or incipient; they were not the usual type of incipient case that the tuberculosis specialists see, in which a person has spit a little blood, or lost a little weight, or had a night sweat or two, who has had, in a word, *some symptom*, however slight, which arouses his own suspicions and leads him to consult a physician, with the consequent discovery of a limited active process. They belonged to the relatively large group too large, which the general practitioner would discover if he carefully auscultated the lungs of all patients consulting him for other and trivial ailments. The lesions in every case were sufficiently plain to be revealed by ordinarily careful work.

There can be no doubt that the lesions in every case represented a much earlier childhood infection, which had failed to become acutely active; and it seems likely that the fine dry râles on cough which were elicited represented a subacute recrudescence caused by the intensive training and hard living. Such men from the point of view of their own welfare might and probably would run an unsafe risk if subjected to the exposure, fatigue and privation of active campaigning. They would certainly be an unsafe risk from the point of view of the government.

Finally, it is interesting to compare the percentage of tuberculosis among the candidates (Table 3) with the corresponding figures for the regulars that we examined (Table 4).

TABLE 4.—RESULTS OF TUBERCULOSIS EXAMINATIONS OF REGULARS

	Number	Per Cent.
Enlisted men examined	584	.....
Accepted	578	98.97
Disqualified because of tuberculosis	5	.85
Recommended for special service	1	.17
Found to have tuberculosis	6	1.027

It will thus be noted that among the candidates, the percentage of tuberculosis was 0.41 per cent., while among the regulars examined it was 1.027 *per cent.*, or more than twice as high.

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

ARSPHENAMINE.* — $HCl.NH_2.OH.C_6H_3.As:As.C_6H_3.OH.NH_2.HCl+2H_2O$. — The hydrochloride of 3-diamino-4-dihydroxy-1-arsenobenzene, corresponding to 31.57 per cent. arsenic (As).

Actions, Uses and Dosage.—The same as those of salvarsan (see New and Nonofficial Remedies, 1917, p. 45).

Arsenobenzol (Dermatological Research Laboratories).—A brand of arsphenamine.

Manufactured by the Dermatological Research Laboratories, Philadelphia Polyclinic, Philadelphia, Pa.

Arsenobenzol (Dermatological Research Laboratories) 0.4 Gm. Ampules.—Each hermetically sealed ampule contains 0.4 Gm.

Arsenobenzol (Dermatological Research Laboratories) 0.6 Gm. Ampules.—Each hermetically sealed ampule contains 0.6 Gm.

Salvarsan.—A brand of arsphenamine.

Manufactured by Farbwerke-Hoechst Co., New York. U. S. patent No. 986,148 (March 7, 1911; expires 1928). U. S. trademark No. 40,734.

Salvarsan 0.6 Gm. Tubes.—Each hermetically sealed tube contains salvarsan 0.6 Gm. (9 grains).

CHLORAMINE-T. — Sodium Para-Toluenesulphochloramide.—$CH_3.C_6H_4.SO_2NaNCl+3H_2O$, 1:4.

Actions, Uses, Dosage, Physical and Chemical Properties.—The same as those of chlorazene (see New and Nonofficial *Remedies, 1917, p. 140*).

Chloramine-T (Calco).—A brand of chloramine-T.

Manufactured by the Calco Chemical Company, Bound Brook, N. J. No U. S. patent or trademark.

NOVOCAINE. — $CH_2(C_6H_4.NH_2.COO).CH_2N(C_2H_5)_2.HCl$. —The monohydrochloride of para-aminobenzoyldiethyl-amino-ethanol.

Actions, Uses and Dosage.—See New and Nonofficial Remedies, 1917, p. 31.

Manufactured by Farbwerke-Hoechst Co., New York. U. S. patent No. 812,554 (Feb. 13, 1906; expires 1923). U. S. trademark No. 53,072.

Health and Recreation Clubs.—In the Albany public schools a campaign is going forward in the formation of health and recreation clubs among the pupils of the sixth, seventh and eighth grades of the entire school system for the improvement of their health and general well being, as well as to cultivate discipline and other good qualities and make better citizens of them. With the cooperation of the board of health and the entire school organization, including the director of health, Dr. Clinton P. McCord, a complete plan for the formation and conduct of these clubs has been worked out, and in the November number of the *Health Messenger*, the school bulletin, prepared and printed in the schools, this plan, including a form of constitution, a club manual, blanks for reporting, rules for the conduct of meetings, inspections, etc., are fully set forth. The organization of the clubs will be effected by the school nurses and teachers with the cooperation of the principals. At the end of the year, health and recreation club certificates will be awarded to those grades attaining certain standards in health habits and recreational activities. This will induce a wholesome rivalry between the boys and girls and between the different grades. This represents an effort in cooperation among the children and youth of the schools for the production of healthier, better citizens that is timely and is deserving of imitation in the schools throughout the country.

---

[*] The Federal Trade Commission adopted the name arsphenamine as the term to apply to 3-diamino-4-dihydroxy-1-arsenobenzene first introduced as salvarsan. The Council on Pharmacy and Chemistry has voted to adopt this abbreviated name in place of arsenphenolamine hydrochloride now in New and Nonofficial Remedies.

Contributors, subscribers and readers will find important information on the second advertising page following the reading matter

SATURDAY, DECEMBER 22, 1917

PRACTICAL ECONOMY

Our Journal in common with all other publications is now paying abnormally high prices for paper, supplies, labor and postage. In addition, letter postage has increased 50 per cent. To offset these extra expenses, it is necessary to economize wherever possible. Under the new postage rate the cost for sending the customary bills for Fellowship and subscriptions and later receipts would total over $4,000.00. One half of this can be saved if each Fellow and subscriber will remit without being individually notified by mail. It is believed that many will gladly do this. Under the circumstances, such notification will not be sent on the first of the year as heretofore. In lieu thereof, a remittance slip is inserted in this issue of The Journal. It is hoped that Fellows and subscribers will cooperate in this effort for economy and accept the remittance slip in place of the annual bill sent in previous years, remitting without further notification.

HOOKWORM INFECTION IN DEEP GOLD MINES IN CALIFORNIA

Hookworm disease, like other maladies associated with a microbiotic origin, can arise whenever the etiologic agent can gain entrance into the body by way of the mouth or respiratory passages, or through the skin after it has been cut or abraded. The larvae of the hookworm also can bore through the intact skin if infected dirt happens to come into contact with the body. When persons living in a hookworm infected region go without shoes, the larvae are enabled to gain entrance to the body through the feet. How persistent the danger may be is evident from the statement current that hookworm eggs will *remain* infectious for a year after they have been evacuated from the intestine. This may be the case when the eggs are exposed to the variable climatic conditions on the surface; but hookworm eggs appear to remain infectious for a period even longer than one year when they are deposited in mines, where temperature conditions remain fairly uniform year in and year out. The insidiousness of the parasite is further emphasized by the fact that it "extends its evil influence in a quiet, cumulative manner, and in different directions." As a sanitarian recently expressed it, a man cannot enjoy normal health while the worms are attached to the inside of his intestine and daily sucking his blood. It should be remembered that although a person with hookworms may not be seriously affected himself, there is always danger of his spreading the infection if he commits a nuisance in a place favorable to the development of the eggs.

The problems of the campaign against hookworm disease are rendered difficult by a variety of conditions in part formerly unanticipated, some of which have recently been discussed in The Journal.[1] Dr. J. G. Cumming, director of the Bureau of Communicable Disease, California State Board of Health, and Joseph H. White,[2] sanitary engineer, U. S. Bureau of Mines, in a report on the control of hookworm infection at the deep gold mines of the Mother Lode, California, furnish added indication of the as yet intangible character of the sources of infection, as they occur in mines. Hookworm infection has long been known to be prevalent among miners in many parts of the world. The importance of its eradication from certain mines is shown by the fact that of the gold miners working underground about 40 per cent. contract this insidious infection in some of the mining districts of California, where it appears almost to be endemic. Aside from the hygienic and humanitarian aspects, the economic loss due to absence from work on account of illness and to inefficiency that cannot be directly measured is a large one. Hookworm infection in mines is a form of industrial disease that must be combated by knowledge of both the industry and the disease. Hence the unusual complexity of the problem.

The ultimate source of infection with hookworm in the California gold mines is not known. The immediate source is, of course, in the discharges from the bowels of those infected. The factors contributory to the spread of hookworm infection operate only after the infectious eggs have been set at large by the careless disposition of human excrement. In mines the soil readily becomes polluted. A miner cannot do his work without getting dirt on his hands and clothing; therefore his safety lies in keeping the dirt of the mine as noninfectious as possible. With a mine once infected, the means whereby the miner becomes infected are obvious. An illustration of the subtle possibilities was furnished by the California investigators in their inspections of miners' shoes. As they

1. Problems in the Campaign Against the Hookworm, editorial, The Journal A. M. A., Nov. 10, 1917, p. 1611; Hookworm in the Mines of China, Nov. 17, 1917, p. 1701.
2. Cumming, J. G., and White, J. H.: Control of Hookworm Infection at the Deep Gold Mines of the Mother Lode, California, Bull. 139, Dept. of Interior, Bureau of Mines, 1917.

remark, hookworm larvae might easily work their way through a fairly good pair of shoes, but the infection would be light. When a mine is known to be infected, a miner should take unusual care to keep his shoes in good repair. At the change house of one infected mine, 107 pairs of miners' shoes were examined, and forty-three pairs, or 40 per cent., were found to be broken or worn so as to permit hookworm infection.

To meet the situation in the Mother Lode mines so as to stop future infection and minimize danger from existing infectious areas, Cumming and White recommend that every employee should be examined for hookworm infection; and every infected miner should be treated until cured. No applicant for work should be employed until he presents a "hookworm certificate" from the California State Board of Health stating that he is free from hookworm infection. All mine workmen should be reexamined about one year from the date of the issuance of the "hookworm certificate." In addition to these personal features the introduction and further extension of suitable sanitary conveniences in the form of toilet facilities is urged. Rats must be exterminated, and the drainage systems improved where necessary. Finally, it is urged by the Bureau of Mines that the miners should be instructed in the causes, nature and prevention of hookworm disease, so that they may know how it is spread, and intelligently subscribe to the remedial measures that are introduced.

THE STATISTICAL EVIDENCE OF CANCER INCREASE

There is no doubt that the number of deaths recorded as due to cancer has shown a marked increase in the last few decades in all cities and countries for which reliable statistics are available. A sharp difference of opinion exists, however, as to whether the reported mortality represents a real or an apparent increase in the disease itself. It is evident that improvements in diagnosis must account for a part of the reported increase, that deaths now recognized to be from certain forms of cancer were earlier not diagnosed as such, but were reported under deaths from "old age" or other ill defined or unknown causes. It is when statisticians attempt to determine the relative importance of this factor in swelling the list of cancer deaths that they encounter statistical difficulties, and split into two groups: those who hold that cancer mortality is increasing more or less rapidly throughout the whole civilized world, and those who hold that the increase is only apparent, not real. The latter group has received a powerful ally in Professor Willcox,[1] who discusses the alleged increase of cancer in a recent weighty monograph.

Willcox first points out that of the previous investigations of this question, two stand in a class by themselves: the study by King and Newsholme in 1893 of data mainly derived from the mortality records of Frankfort, Germany, and the more recent study (1915) by Hoffman of cancer throughout the world. It is significant of the difficulties attending such inquiries that these two studies reach diametrically opposite conclusions.

Willcox analyzes the essential data comprehensively and subtly. Perhaps the most generally interesting portion of his paper is the reexamination of the Frankfort figures, with its extension of the period covered from thirty years (1860-1889) to fifty-four years (1860-1913), and the inclusion of 9,000 deaths instead of 3,000. The Frankfort tables and diagrams show that during this period there has been no significant change in the small mortality from accessible cancer of men, and that there have been irregular changes followed by a remarkable uniformity in the mortality from accessible cancer of women. Almost all the increase occurred in the mortality from inaccessible cancer. Study of this important material therefore indicates in Willcox's opinion that the apparent cancer increase in Frankfort was probably due entirely to improved diagnosis.

Another conclusion reached is that probably not less than one tenth of the reported increase of cancer mortality is due to changes in the sex and age composition of the population. With reference to the different sex incidence he says:

> Cancer mortality is lower but increasing faster among men than among women. Both differences may be due to the fact that among men the organs chiefly attacked by cancer are inaccessible, while among women they are accessible. Hence the scope for improving the diagnosis of cancer among men was and is much wider.

Two important pieces of evidence drawn from American statistics also may be mentioned. The deaths ascribed to unknown or ill defined causes in the American registration states (of 1900) decreased between 1900 and 1915 to one tenth of the initial number. "If these deaths no longer ascribed to ill defined or unknown causes were distributed over the other causes in a random way, the transfer to cancer accounted for about one ninth of the increase in the reported mortality from that disease." This is certainly not an overstatement. Similarly the deaths ascribed to old age in the same American registration states decreased between 1900 and 1915 to a little more than two fifths of the initial figures; the death rate from this reported "cause" was lowered still more, to less than one third. There can be no doubt that a considerable proportion of the apparent cancer increase—Willcox puts it as at least one eighth—was due to transfer from the old age column to the cancer column.

Willcox points out also that the reported negro cancer mortality is lower than the white, but is increasing more rapidly, seeming to indicate here also the influence of the relative correctness of diagnosis. He also notes that the increase in reported appendicitis mortality in England and the United States is parallel with the increase in reported cancer mortality, and intimates that both may be due entirely, as they certainly are in large part, to the improvement of diagnosis. The whole argument leaves one in a frame of mind tentatively to accept Willcox's conclusions:

---

[1] Willcox, F. W.: On the Alleged Increase of Cancer, Quarterly Publications of the American Statistical Association, 1917, 15, 701.

> The cumulative evidence that improvements in diagnosis and changes in age composition explain away more than half and perhaps all of the apparent increase in cancer mortality rebuts the presumption raised by the figures, and makes it probable, although far from certain, that cancer mortality is not increasing.

THE NATURE OF MUSCULAR CONTRACTION

The theories as to the nature of muscular contraction have undergone profound changes since the opening of the twentieth century. Only a few years ago the working mechanism was still freely compared with a steam engine in which the direct combustion of fuel leads to the liberation of energy in the form of heat and motion. This analogy between the muscle and a heat engine received its greatest setback in the demonstration that muscular contraction is still possible in the absence of oxygen, without which true combustion promptly fails. As a sequence came the views that somehow very unstable energy-yielding compounds are built up in the contractile tissue, and that these disintegrate somewhat like the reaction of an explosive so as to do work. The chemical processes involved were vaguely conceived to consist essentially in "the building up of elaborate, unstable and oxygen-charged molecules, by the processes of so-called 'anabolism,' into the mystical complexes of irritable protoplasm." From the latter, energy was supposed to be discharged when the proper stimulus set off the charge, so to speak.

It is obvious that there must be something in a resting muscle which possesses some sort of potential energy; for when a muscle contracts, tension is developed and external work is done if the tension is made use of in processes requiring expenditure of energy. The energy of tension may also be allowed to appear in the form of heat. The nature of the processes involved have been greatly elucidated in recent years by the work of the Cambridge school of physiologists in England, notably Fletcher, Hopkins and Hill.[1] Today we know that the actual contractile process is not associated directly with the giving off of carbon dioxid or with the consumption of oxygen. Lactic acid is formed; but the chemical change up to this stage is not an oxidative process. What oxygen does is to remove by oxidation or otherwise the lactic acid produced by contraction. Precisely how this happens is as yet a mystery, made more obscure by the fact that outside the muscle, in the circulation, for instance, lactic acid is not directly oxidizable at physiologic temperatures. Nevertheless the dissipation of the lactic acid that is an accompaniment of the contractile process is highly important, however it may be accomplished; for lactic acid is the most obvious determining cause of the signs of fatigue; and recovery from fatigue depends in no small measure on the removal of this acid compound. Somehow, with the destruction or removal of the lactic acid, the energy of the muscular system is restored.

From this standpoint there are two chemical events involved in muscle incident to its function. The act of contraction itself is now known to be an anaerobic process independent of oxygen, but accompanied by the formation of lactic acid. In the second stage of functioning, whereby the lactic acid is removed again, oxygen plays a prominent part. We may quote Fletcher and Hopkins' formulation of these phenomena. The special processes, they state, which, when they occur within a muscle fiber, culminate in a contraction, make no call on an oxygen supply; they proceed anaerobically. The oxidations which are always associated with muscular activity are separated in time from that moment in which mechanical energy is liberated. They occur immediately afterward, and are concerned not with the introduction of the mechanical act, but with a restoration to the status quo ante. They are concerned not with stimulation but with recuperation.

Is the production of lactic acid to be regarded, then, as an undesirable incident and the substance itself as a toxic product, destined to be eliminated or destroyed as speedily as possible? Certainly not in the light of the newer conceptions, in which the acid serves as an essential agent in the machinery of contraction itself. To quote the Croonian lecturers again, the development of acid, with free hydrogen ions, in the neighborhood of colloidal fibrils gives the condition for contraction, either by increasing the molecular tension along longitudinal surfaces or by the process of imbibition, causing a resultant increase of tension in the fiber. The removal of lactic acid under the influence of oxygen will give relaxation, as the original state of tension in the fibril is restored.

The Cambridge investigators conclude that in the muscle, which, after all, forms the chief seat of metabolism, the acid intermediary product appears at such a stage and place as to have more than a purely chemical significance. It marks, on the one hand, an obligatory stage in a particular set of successive chemical reactions; but, on the other hand, it has here its special rôle to play in connection with the muscle machinery. In the evolution of muscle it would appear that advantage, so to speak, has been taken of this acid phase in carbohydrate degradation, and that by appropriate arrangement of the cell elements the lactic acid, before it leaves the tissue in its final combustion, is assigned the particular position in which it can induce those tension changes on which all the wonders of animal movement depend.

---

[1] An account of some of this development is given by Fletcher, W. M., and Hopkins, F. G.: The Respiratory Process in Muscle and the Nature of Muscular Motion, Croonian Lecture, Proc. Roy. Soc., B, 1917, 89, 444.

Such conceptions carry us far away from the earlier views as to the mechanism of muscular contraction. We can no longer look on the muscle as a simple human heat engine. We are dealing in muscular work with something of a physical as well as a chemical nature. The potential energy must be in the form of surface energy or osmotic energy or both; in any event it is not directly associated with an oxidative chemical reaction of the familiar sort. In the words of Fletcher and Hopkins:

> With an understanding that the relatively permanent physicochemical system of the muscle can, without itself undergoing chemical modification, carry changes of potential as a result of changes in its physical configuration, it becomes easier for us to realize that the foodstuffs, or at least that sugar, may be the direct source of the contractile energy. Placed in the right locality within the muscle, sugar, by a nonoxidative yield of acid at the right moment, and by a subsequent oxidation of this at another right moment, can yield its total energy in a manner exactly suited to serve the peculiar machinery in which, so to speak, it finds itself.

NEW EVIDENCE REGARDING THE FAT-SPLITTING FERMENT OF THE STOMACH

Where does the digestion of fats begin in the alimentary tract? Until only a few years ago the digestive cleavage of these foodstuffs was supposed to be a function of secretions poured into the gastro-intestinal canal somewhere beyond the stomach. An occasional investigation, it is true, had revealed the existence of small quantities of fatty acids in the contents of the latter organ after the ingestion of considerable fat; but it was not until the unexpected findings of Volhard published in 1900 regarding the existence of a fat-splitting enzyme in the stomach that the possibility of any significant gastric digestion of fats was taken seriously into consideration. A decade later von Fürth,[1] in reviewing the literature on the probable first phase of fat digestion, concluded that doubtless the stomach contains a lipolytic ferment, and that physiologically the cleavage of fats begins at this point; but he believed that the lipolytic power of pure gastric juice is distinctly less than was earlier assumed. Von Fürth attached no particular physiologic importance to possible lipolytic processes in the stomach.

The question here at issue became greatly complicated by the realization, now grown to a firm conviction, that after the taking of foods of various sorts — and particularly after a meal of fatty food — it is easy to have a reflux of duodenal contents into the stomach. Obviously the pancreatic and intestinal fat-splitting enzymes may thus gain entrance into this organ. Is this, then, the true explanation of the source of the reputed gastric lipase? The failure of the earlier workers to rule out the regurgitation of pancreatic juice from the intestine as a source of lipase in the stomach, coupled with the low values for gastric lipase reported for the gastric juice by those who have examined purer specimens of the secretion, has thrown doubt on the actual existence of such an enzyme as a product truly elaborated by the gastric membrane.

It would not be surprising to find in the stomach secretion traces of any familiar enzyme occurring in abundance elsewhere in the body. Enzymes that find their way into the blood stream are known to "escape" into the gastric juice. The circulating fluids of the body do, in fact, contain some lipase. But if we may judge by the new observations of Hull and Keeton[2] at the Northwestern University Medical School, Chicago, this will not explain the appearance of gastric lipase, which they find in pure gastric juice in a concentration five or six times that in the succus entericus and the blood serum. They searched for lipase in gastric juice collected so that no contamination with intestinal or pancreatic products was possible. In the course of the investigation it developed that gastric lipase is a very unstable substance, a fact which at length explains the failure of many who have searched for the enzyme to find it. The fasting and acid-free juice always contains an appreciable concentration of lipase; it is, however, sufficiently sensitive to alkali or acid to be destroyed by a fifteen minute exposure to hydrochloric acid of the concentration (0.2 per cent.) frequently found in the stomach contents. The enzyme may be recovered from the stomach showing low acid secretion by immediate neutralization of the juice, and from stomachs in high secretory activity, if the acid is reduced by the addition of protein.

The Chicago investigators come to the conclusion that lipase is a true gastric secretory product, rather than an accidental "contamination" of the stomach contents. The persistence of the lipase in the stomach, they maintain, certainly seems to be a function of the free acidity. An acidity of 0.2 per cent. of hydrochloric acid appears to be about the upper limit for the recognition of much lipase, but in clinical observation this free acidity is not soon reached in the normal stomach under the usual diet conditions with average amounts of protein present to hold the acid. It is highly probable, therefore, that before the acid can accumulate to the point at which it can more than saturate the proteins, the lipase enzyme will have an opportunity of doing appreciable work, as the ptyalin of the saliva certainly does and as administered trypsin must do also, according to the investigation of Long and Hull.[3] At any rate, the possible importance of gastric lipolytic activity in the sum total of alimentary digestive performances is once more deserving of respectful consideration.

Current Comment

WINTER POLIOMYELITIS

The relative rarity of winter outbreaks of poliomyelitis is one of the chief reasons why officers of the United States Public Health Service have recorded in detail an epidemic occurring in Elkins, W. Va., in 1916-1917.[4] The investigation in West Virginia has especial significance in showing the great importance of unrecognized cases and of carriers in the spread of the disease. The investigators were led to believe that types of nonparalytic poliomyelitis exist in which the symptoms are referred in the first instance to the digestive tract. These cases of digestive disturbance of slight severity are very likely an important source in the spread of poliomyelitis infection. The facts discovered in this outbreak are considered to emphasize the importance of human contact in spreading infection. No connection was found between general cleanliness, insect prevalence and similar factors, and the incidence of the disease. Indirect contact through adult passive carriers is considered as particularly important. As a measure of administrative control, the authors lay stress on the minimizing of general intermingling of adults and children, especially at times when poliomyelitis is prevalent.

THE FATE OF STRYCHNIN IN THE BODY

Strychnin has so long been employed in therapy, and has also been so conspicuous as a dangerous poison, that the question of its precise behavior in the organism has attained considerable prominence. Despite this, much of the essentially desirable information on the subject has been a mass of contradictions and confusion. This statement applies in particular to the fundamental questions as to how the alkaloid is excreted from the body and whether it experiences any alteration, deposition or destruction in its passage through the organism. From a medicolegal standpoint it has further been of decided interest to ascertain whether strychnin disappears in the course of postmortem changes attended with putrefaction; for on the answer to this hinges in no small degree the possibility of our identifying the poison in the body in which it has wrought its havoc. These problems have been subjected to renewed experimental study in the pharmacologic laboratory of the Cornell University Medical College, by Hatcher and Eggleston.[5] They found that total amounts of strychnin equal to several times a single fatal dose may be administered to experimental animals in fractional doses on each of several successive days without causing permanent injury. From this clearly established fact it must be assumed that the poison is promptly disposed of in some way. It may come as a surprise to many to learn that only a small percentage of repeated toxic doses of strychnin can be recovered from the urine. Whatever is found in this excretion makes its appearance very soon after the administration of the substance. None can be recovered a day after the cessation of the dosage. The poison, administered parenterally without lethal effects, cannot be found in the feces. These facts, evincing the failure to detect in the excreta the bulk of administered strychnin, thus point to its deposition or destruction in the body. The latter outcome seems most probable in view of the practical failure of Hatcher and Eggleston to recover the alkaloid from the tissues even after administration of very large amounts, provided death did not ensue too speedily. The often made statement that strychnin is not decomposed during putrefaction appears to be quite untenable. These findings, based on careful experimentation, are believed to clear up some of the confusion in the literature. They may not render the task of the toxicologic chemist easier in his search for evidence of strychnin in the body; but they throw light on the tolerance of the organism and its capacities for defense against harm.

CITRIC ACID IN THE URINE

The announcement has just been made by Amberg and McClure[1] that normal human urine contains citric acid. It is asserted that the amount excreted in the course of twenty-four hours is quite appreciable—"enough to play a modest rôle in the acid-base economy of the organism." One naturally thinks of food sources for the excreted product. Citric acid is found in such fruits as oranges and lemons, and it is stated to occur to the extent of from 0.05 to 0.1 per cent. in human and cow's milk. Feeding experiments with citrates make it less probable, however, that the citric acid in the urine should come from the material ingested, since the latter seems to be destroyed with considerable ease in the body. In view of the alleged constant occurrence of citric acid in another product, milk, that fraction now said to be present in the urine may likewise have an endogenous origin. The evidence furnished by the Chicago biochemists regarding the output of citric acid is indirect and therefore not absolutely convincing. Pending more rigorous proof, speculation as to its origin may therefore well be suspended.

War Cripples.—The attitude of the public toward the returned soldier will do much to make or mar the success of work with war cripples. The cripple returning from the front deserves the whole hearted gratitude and respect of the nation, but to spoil and pamper him is an ill-advised way of meeting the obligation.—McMurtrie, Columbia War Papers

Medical Mobilization and the War

RED CROSS GETS NOBEL PRIZE

The International Red Cross Committee of Geneva has been awarded the Nobel Peace Prize for 1917, and by unanimous consent of the custodians of the special fund, the prize of 1916, which was not bestowed last year, was added to this award.

WOUNDED IN ACTION

The War Department received advices, December 11, from General Pershing, that Lieut. Edgar W. Young, M. R. C., McKinney, Va., a graduate of Baltimore Medical College, in 1911, had been seriously wounded in action.——Advices from France, December 16, state that Lieut. H. Cotter Boyle, M. R. C., of Luzerne, Pa., a graduate of Temple University, Philadelphia, in 1914, had been seriously wounded, December 7, while on duty with the British forces.

MEDICAL RESERVE OFFICERS AT WEST POINT

Major W. H. Haskin, M. R. C., U. S. Army, writes from West Point that the entire medical staff at the Military Academy are Medical Reserve Corps men. The personnel is as follows: Major W. H. Haskin, Lieuts. J. F. Grattan, J. D. Kelly, Sutherland Miller and Kenneth Phelps; Dental Corps, Lieutenants Bachman and C. Van de Water; veterinarian, Lieutenant Churchill.

MOVING PICTURES AND OTHER ILLUSTRATIONS FOR THE ARMY MEDICAL DEPARTMENT

The Surgeon-General has authorized the establishment at the Surgeon-General's Library and Army Medical Museum, Seventh and B Streets, S.W., Washington, D. C., of a repository for moving pictures, slides and photographs of camp and other activities related to the work of the Medical Department. These illustrations are to be made available for instruction purposes in camps, cantonments, etc., and will be lent for use in conjunction with lectures and other courses of study in medical schools, training camps and cantonments. Donations of such illustrations are solicited.

MILITARY ROENTGENOLOGY CLASS ORGANIZES

The class in military roentgenology in the course conducted by Capt. E. S. Blaine at the Cook County Hospital, Chicago, has arranged for a permanent organization. The class is composed of thirty physicians from fourteen different states: Iowa, Indiana, Tennessee, Florida, Wisconsin, Texas, New York, Illinois, Alabama, Minnesota, Ohio, Nebraska, Kentucky and Michigan. The work is not limited to military roentgenology, but each member is required to do radiography, fluoroscopy, therapy, developing and diagnosis. In the permanent organization Lieut. Thomas D. Cantrell of Bloomington, Ill., was chosen president, and Capt. D. W. Young of Paris, Ill., secretary.

VOLUNTEER SERVICE IN SOME BRANCHES FOR MEN REGISTERED UNDER SELECTIVE SERVICE

Under date of December 17 the Provost Marshal issued to the governors of the various states an announcement that men of draft age may still volunteer for certain branches of the service. White men only will be accepted and they may enlist only in the Infantry, Signal Corps, Medical Corps and Quartermaster's Department. All men enlisted for the Medical Department will be sent to the Medical Officers' Training Camp at Fort Riley by local boards west of the Mississippi, and to the Medical Officers' Training Camp at Fort Oglethorpe, Ga., by boards east of the Mississippi. Transportation and subsistence expenses to the camps are to be furnished volunteers by the local boards.

PAMPHLETS ON VENEREAL DISEASES

The Illinois Vigilance Association has prepared for distribution several pamphlets on venereal diseases which it offers to send free of charge, transportation prepaid, to any Army officer or medical officer who will ask for them and use them carefully among the soldiers. It also offers to send single copies free of charge to any physician on receipt of a self-addressed, stamped envelop. The pamphlets consist of one entitled "For Our Daughters" by Dr. Charles Burlureaux of the French Society of Sanitary and Moral Prophylaxis; one entitled "For Our Sons" by Professor Alfred Fournier; three Great Army Records by Wirt W. Hallam, and a pamphlet containing Lord Kitchener's "Instructions to Soldiers" and an article by Prof. William T. Belfield. The address of the Illinois Vigilance Association is 58 West Washington Street, Chicago.

WAR REVENUE LAWS AND THE DISPENSING OF ALCOHOL BY PHYSICIANS

Under the War Revenue Act of Oct. 3, 1917, which went into effect, Dec. 1, 1917, hospitals, sanatoriums and physicians who use alcohol for nonbeverage purposes are required to file a bond and obtain a permit from the revenue authorities. This law is being administered in connection with the Food Control Act of Aug. 10, 1917, and applies to every one handling alcohol. Heavy penalties are provided for noncompliance with or violation of the law. Physicians should make themselves conversant with the requirements if they have not already complied with the law. Druggists may not sell to physicians, hospitals or sanatoriums nonmedicated alcohol unless the physician, hospital or sanatorium has filed the required bond and obtained a permit. Druggists may, however, sell alcohol to physicians or the general public in any quantity up to 1 pint provided it is rendered nondrinkable by a prescribed proportion of the following substances: phenol, formaldehyd, mercuric chlorid, hydrochloric acid, tannic acid, alum, lysol or liquor cresolis compositus. A druggist having a permit may fill a physician's prescription or a physician with a permit may dispense prescriptions containing alcohol provided the prescription contains other drugs sufficient to render the alcohol unfit for beverage purposes. To be able to purchase nonbeverage alcohol physicians, hospitals and sanatoriums must, in addition to having filed the bond and obtained the permit, order such alcohol on a form prescribed by the law. The penal sum of the bond must equal $3 for each proof (50 per cent.) gallon of alcohol expected to be on hand or in transit at any one time. The bond must be that of a surety company, or a personal bond signed by two sureties approved by the collector of internal revenue, or may be a personal bond secured by a deposit of liberty or other government bonds. More complete information may be obtained from the district revenue officers.

SUMMARY OF HEALTH CONDITIONS IN CAMPS OF UNITED STATES FOR WEEK ENDING DEC. 14, 1917

National Guard

With the exception of the Thirty-Fourth (Camp Cody), Thirty-Fifth (Camp Doniphan) and Fortieth (Camp Kearny) divisions, but few new cases of measles are reported from National Guard camps. In each of the divisions mentioned, with the exception of the Fortieth, the number of new cases is small as compared with the number reported for last week. In the Fortieth Division the number of new cases is 330 as compared with 279 for the previous week.

Pneumonia following measles is also rapidly decreasing in amount in all but three of the divisions in which measles has been epidemic. In the three divisions referred to, Thirtieth (Camp Sevier), Thirty-Fourth (Camp Cody), and Thirty-Ninth (Camp Beauregard), an increase in the number of cases is noted, although the total number of new cases reported in each division is not high.

For meningitis the number of new cases has increased in but two camps of the National Guard. The Thirty-Fifth (Camp Doniphan) Division reports six new cases as compared with two for the previous week and the Thirtieth (Camp Sevier) Division reports six as compared with one for the previous week. The number of new cases reported in the Thirty-Sixth (Camp Bowie) Division has decidedly decreased. The highest number of new cases reported in any other division of the National Guard is three.

National Army

In the National Army a marked increase has occurred in the number of new cases of measles in the Eighty-Seventh (Camp Pike) and Ninetieth (Camp Travis) divisions, and a slight increase in the Eighty-Ninth (Camp Funston) Division. In all other divisions the number of new cases of measles reported is insignificant.

Pneumonia conditions in all divisions of the National Army have decidedly improved during the week, except in the Ninetieth (Camp Travis) Division, in which an increase of thirty-six new cases is reported over the report of last week.

As regards meningitis, the Eighty-First (Camp Jackson) Division reports a marked increase in the number of new cases over the report of last week. The outbreak of this disease in the Eighty-Ninth (Camp Funston) Division continues to decline, but eight new cases having been reported during the week. The highest number of new cases reported in other divisions of the National Army is five. Seven divisions of the National Army reported new cases of this disease during the week.

NEWS OF THE BASE HOSPITALS

Base Hospital No. 22, Milwaukee, Wis., has been mobilized under the command of Col. Thomas Jellis Kirkpatrick, at the Light Horse Squadron Armory in Milwaukee. This unit is fully equipped, the equipment containing full hospital equipment for a 500 bed hospital, including 500 iron beds, 1,500 blankets and all accessories needed, a complete indoor telephone equipment, a complete supply of medicines, surgical dressings and surgical instruments, special eye, brain and jaw instruments, a $7,500 roentgen-ray apparatus, including 500 roentgen-ray plates, a giant magnet, complete dental outfit, three White ambulances completely equipped, one 3-ton White motor truck, one Hudson seven-passenger officers' car, one motorcycle, a fully equipped kitchen outfit, and a "Kinyoun" portable bed disinfector capable of sterilizing ten bed mattresses at one time.

Most of the professional staff have received training at medical schools and army camps. Major Curtis Evans, the director of the base hospital, has been for the last three months at the neurologic school at Philadelphia taking the course in brain surgery. Captain Beffel and Lieutenant Lillie were there with him. Major Otho Fiedler has taken the Carrel course in New York and is now at the Rockefeller Institute taking a laboratory course. Captain Gilchrist is at Fort Travis with the base hospital there. Lieutenants Eagan, Rueth and Fitzgerald are at Fort Riley. Lieutenant Foerster is taking a course in New York City. Lieutenants Senn and Brook are at Waco, Texas.

In the absence of Director Evans, Major Robert Curtis Brown has been acting director. Capt. Oscar Lademan has been doing special work in examination of heart and lungs at Fort Oglethorpe. Lieutenants Campbell and Siewart have been taking special courses in dental surgery. Major Ruhland, Captains Ivy and Harry Gradle will continue in their present service.

The following is the personnel of the hospital: Majors Curtis A. Evans, director, chief surgeon; Robert Curtis Brown, chief of medical service; Otho Fiedler, staff surgeon; Capts. Henry B. Hitz, staff surgeon, ear, nose and throat; John W. Means, oral surgeon; Herbert Walker, ophthalmology; Philip F. Rogers, staff surgeon; Eugene A. Smith, staff surgeon, roentgenologist; John M. Beffel, Francis A. Thompson and Oscar E. Lademan, staff physicians; Lindsey Dennison, quartermaster; Lieuts. Ralph T. Gilchrist, chief of laboratory; Allen Sivyer, assistant in laboratory; Orville R. Lillie, Francis B. McMahon, Ulrich Senn, William J. Egan and Edward Rueth, staff surgeons; Harry Robert Foerster, Delparde W. Roberts, Jeffry J. Brook and George M. Fitzgerald, staff physicians; Stephen Campbell and George B. Siewart, dentists; Paul B. Jenkins, chaplain, and H. I. Rice, first sergeant.

The University of Minnesota Unit, Base Hospital No. 26, is mobilizing on the university campus under orders from the War Department, and will soon be ready to entrain for Fort McPherson, Ga., when the date for departure is definitely settled. Advance notice had been received asking the unit to be ready for mobilization, and the order to mobilize found the hospital fully equipped and prepared with the quarters for the men ready when they were told to report. This unit is a combination of the University of Minnesota and the Mayo Clinic. The commissioned officers include Majors Arthur A. Law, director and chief surgeon of the university, and S. Marx White, chief of medicine; Capts. E. C. Moore, Los Angeles; Robert D. Mussey, Carl Fisher, opthalmology and otolaryngology of the Mayo Clinic, and John Bentler, quartermaster; Charles A. Reed, orthopedics, Angus Morrison, neurologist; Gilbert J. Thomas, urologist; Harry B. Zimmerman and John Staley of the university; Lieuts. Alexander B. Moore, roentgenologist; W. W. Bissell, chief of laboratory; David M. Berkman, James M. Hayes, Fred Rankin and Thaddeus L. Sclapka of the Mayo Clinic, and Moses Barron, Archibald Beard, O. M. Klingen, Thomas Snodgrass, Gordon M. Clark and Taylor B. Smith of the university.

NEWS OF THE TRAINING CAMPS

Fort Riley

The event of the past week was the visit to the camp last Saturday of Surgeon-General Gorgas. He was accompanied by Col. D. C. Howard, M. C., U. S. Army; Major Victor C. Vaughan, M. R. C., and Prof. William Welch of Johns Hopkins University Medical School. The morning was spent in Camp Funston, inspecting the camp with special reference to contagious diseases and the inauguration of methods for their prevention. Particular attention was given to meningitis and pneumonia. The afternoon was devoted to the medical officers training camp. At 3:30 all the officers, instructors and students met in the Y. M. C. A. auditorium. General Gorgas was introduced by Colonel Bispham, and spoke to the officers on the work of the Medical Corps. Short talks were also made by Major Vaughan and Professor Welch.

An isolation camp has been established between Fort Riley and Camp Funston, with about 1,600 men. A new isolation camp on the western edge of the reservation is now being built with a capacity of 2,500. To this camp are sent all newly arrived men and all old men coming back on leave. The work being done here is evidently recognized, as the Surgeon-General has just asked for three men from the contagious disease squad to be sent to Camp Doniphan for meningitis field work.

Winter has descended on the camp with a rush. After long weeks of unbroken Indian summer, we had come to believe that the much dreaded Kansas winter was a myth and that a heavy overcoat was an unnecessary luxury. But the last week has undeceived the most skeptical. Thursday was gloomy, with a strong wind gradually working around into the North. Friday brought a few snowflakes and a temperature of about 10 degrees above zero. Saturday night was 5 degrees below. Since then, the temperature has depended on the brand of the thermometer and the imagination of the observer. Fifteen degrees below zero was reported one night, but this has not been officially confirmed. For the past six days the mercury has hovered near zero most of the time; but the work of the camp has gone on without interruption. Drills, horseback riding and maneuvers have been held the same as usual. Little personal inconvenience has been experienced. The company barracks had all been lined and boarded up in anticipation of cold weather, while the officers' quarters had been weather-proofed largely according to the judgment or ingenuity of the occupants. Stoves and an abundance of coal kept barracks, quarters or mess halls comfortable. Sheeplined coats, knit helmets, fur caps and heavy gloves have suddenly become popular. In spite of zero weather, windows are opened wide at night, the officer of the day inspecting all barracks at regular intervals each night to insure adequate ventilation. The health of the camp has been excellent, only two or three being on the sick list out of nearly 550 officers. In spite of the cold weather, the largest number of officers on the sick report any one day was three, on two days there was one each and on one day two, making a total of fifteen cases for seven days, or an average of two per day, 0.36 per cent., or 3.6 per thousand. Evidently, the medical officers' training camp would be an extremely poor place for any man to start in the practice of medicine.

The first instalments of student officers for the third training camp are now coming in, about 150 having arrived during the past week. Cold weather has made all trains late, so that some of the men reached camp after dark or even late at night. Company 14 has been filled and Company 15 started. These new companies are in the barracks formerly occupied by Companies 1 and 2. The regular schedule for Company 14 started Monday. Company 15 will begin its class work next Monday. The contrast between civilian life in steam-heated houses and office buildings and camp life in barracks is much greater to the men reporting for duty now than to those who began their work in the summer. But the new men are settling down to their work in dead earnest.

White collars are soon replaced by flannel shirts, and caps by field hats. While the cold weather has made drilling and hiking heroic experiences for men fresh from civilian life, there is no shirking. The new officers are taking hold with determination. Of course, the usual jokes are being attempted. Several newly arrived officers have visited the quartermaster, earnestly asking where they can secure the "O. D. Regulation Officer's Umbrella." Some have reported to the adjutant's office and asked for "butter checks," while a number have made careful search all over camp for "Colonel Latrine's headquarters" so that they might report for fatigue duty as directed. But these stereotyped camp jokes are accepted good naturedly as a part of the game, and in a few weeks the new "Docs" have ceased to be rookies, and are ready to help take in those who have come in since their own arrival.

THE FUNCTION OF ORTHOPEDIC SURGERY IN THE WAR

The Philadelphia County Medical Society in its meeting of Nov. 28, 1917, heard several papers descriptive of the work of the orthopedic section of the Surgeon-General's Office and the plans for reconstruction after the war. Major David Silver, Pittsburgh, vice chairman, orthopedic section, Surgeon-General's Office, states that in organization of the work of orthopedic surgery the Surgeon-General has been guided very largely by the experience of the English army and has, in addition, paid special reference to: (1) the securing of a sufficient personnel; (2) provision for an ample number of beds, and (3) the reception of the wounded soldier as early as possible in the division to which he belongs and with the least possible change of dressing. There are now about eighty-five men in training in Europe, sixty men assigned to camps in this country, and eighty or more placed in courses of instruction, with a considerable number still unassigned. Especial attention has been paid to the training of men who did not have a sufficient fundamental knowledge of orthopedic surgery. For these men the plan of instruction consists of intensive courses of six weeks' duration, work in the cantonment hospitals under qualified orthopedic surgeons, and later, work abroad as assistants to qualified men.

Efforts are also being made to instruct the medical men generally, the line officers, and the enlisted men themselves in the care of the feet, the handling of minor joint injuries, and the simpler injuries of the back.

In the plan for the organization of the work in France, the Surgeon-General has arranged for the establishment of an orthopedic section in each hospital, and this will be placed beside the fracture section in order that the same brace shop and curative workshops may be used for the two. From 5 to 7.5 per cent. of the wounded are expected to be returned to this country, and these will be placed in the general reconstruction hospitals that are being planned in the various sections of the country. Here the reeducational work will be carried out.

The Surgeon-General has established a laboratory for the study of the various problems connected with artificial limbs. There will not be much difficulty in the supplying of artificial legs to the soldiers, as this has reached a high degree of perfection in the hands of the American manufacturer. The substitute arm is naturally, however, not so satisfactory on account of the complicated demands that are made on it when we attempt to supply the functions performed by the normal hand. So far it has been found more satisfactory to use some form of mechanical hook for labor, reserving the hand for social use.

Orthopedic surgery is concerned also with the industrial problem, which is as important as that of the military. The comparison of statistics clearly demonstrates the great importance of applying the same plan that has proved so valuable in military work to industrial work as well. In war we may have a great many casualties in one day, while in industry the number of daily accidents is small; this loss, however, is continuous, so that the economic loss of industrial accidents in the long run assumes an equal importance to the casualties in war. In view of the probable industrial struggle that will follow immediately after the conclusion of the present war, it is of vital importance that the reeducational plan be so made as to embrace both the military and the industrial need.

The Civic Aspects of Orthopedic Surgery in the War

Major Henry R. Hayes analyzed the problem of reconstruction. While this might not seem to be a large problem, analysis reveals its extent. A man returned disabled for service will probably need, in addition to the surgical treatment overseas, further surgical and curative treatment at home. His medical and mental limitations with relation to the character of his previous occupation in civil life must be carefully studied by the medical and vocational staff to determine the specific training he shall have. Surgeons and physicians must tell us what men with given disabilities cannot do. Experts in vocational training must advise what trades to teach the disabled. Employers and employees must advise us on the local trade and labor markets. There must be fundamental organization, that employers and employees may not be asked to take unreasonable risks; and there must not be discrimination against the crippled. A man reconstructed and reeducated must be presented to society, equipped to earn the pay of a given job.

Exemptions under the National Army draft law for physical disabilities have been astonishingly large, and not a small number of such disabilities are orthopedic in character. This situation is being studied by one department of the government, that such disabilities in the younger and future generations may be minimized. Reconstruction work, therefore, will require the close cooperation of Army federal bureaus, and state and local official and civilian organizations.

Dr. G. G. Davis, member of the Orthopedic Advisory Council, thought it strange that a great war should have been necessary to arouse the people to a sense of their responsibility. We speak, for instance, of the military reconstruction, the importance of the reconstruction in industrial enterprises; but the purely civil cripple is not yet receiving a fair chance. All through our community there is a class of cripples that cannot receive treatment because of the lack of provision. This problem has occupied the attention of the orthopedic profession but it seems to have required the war to make the people appreciate its importance.

Dr. A. Bruce Gill believed that it would be difficult to find experts in teaching trades to cripples, since the work is in its very beginning. No evil is unmixed, and the opportunity for the cripple from this time will be such as it never was before. Only four states in the Union have given any state attention to this work. There will be required cooperation and study to equip and find industrial positions for the cripples that will be returned to us after the war.

Dr. Charles K. Mills noted that the War Department is sending to Philadelphia military men who are receiving special training in certain courses of instruction; but these different classes have not been coordinated. There are a neuropsychiatric class, a neurologic surgical, and an orthopedic group. The relations of orthopedic surgery to neurology are most important. That which should most concern us in the treatment of cripples is the diagnostic study. The first consideration should be a knowledge of the various conditions of the nervous muscular system, bones and joints responsible for such cases. While the greatest possible attention should be paid to the training of men for orthopedic work, their studies should be devoted to a very considerable degree to neural medicine. There are cases in this war which bring back the statements of Sir Benjamin Brodies and of Sir James Paget that functional hysteria was due not to organic injury of nerve, muscle, bone or tendon, but to certain special conditions of the nervous system. Every orthopedic base hospital or reconstruction hospital should have, and doubtless will have, a neurologic member on its staff. One of the great hospitals with which Dr. Davis is connected is the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases. This combination of work was brought about by the great neurologist, S. Weir Mitchell, and Dr. Thomas G. Morton, surgeon, and the institution has obtained results that would have been impossible had there not been this coördination of neurology and surgery.

Major Silver, in closing, said that one distinction most important to make is that orthopedic and reconstruction are not synonymous terms. The point emphasized by Dr. Davis of the urgent need of carrying out orthopedic work in our general hospitals is one of the most important points in our industrial problems. Men discharged from the hospital failing to follow directions, or given no directions, acquire atrophy from disuse of an injured member. We must supply the missing link so that men are physically restored before they are allowed to leave the hospital. The question of the experts mentioned by Dr. Gill presents a difficult problem; yet, any one who has seen what is done by these men with amputated limbs will not ask for more finished experts than they are. One man with one arm amputated is a dentist. In reeducating these crippled soldiers, we shall be the ones who are reeducated.

NEWS OF THE CANTONMENTS

Twenty-Eighth Division, Camp Hancock, Augusta, Ga.

Dec. 9, 1917.

Friday, December 7, Major Stiles, the hookworm expert, of the United States Public Health Service, addressed the surgeons of the Twenty-Eighth Division on the subject of diseases of the southern negro, and care of troops in the South.

During the past week the Inspector-General of the Army has been making a close inspection of the division.

Thirty-First Division, Camp Wheeler, Macon, Ga.

Dec. 12, 1917.

The two epidemics of measles and pneumonia appear to have come to an end. While it was suspected that there was some connection between the two, it was not known that the connection was so intimate until the figures were tabulated. It was then seen that the curve for pneumonia rose following the rise for measles, reached an apex twelve days after the measles apex, and fell in the same manner. The collected figures showed that approximately 45 per cent. of the pneumonia followed measles. Of some 3,000 cases of measles approximately 7 per cent. were followed by pneumonia. Moreover the measles pneumonia was very much more fatal than the independent pneumonia. There is no longer any doubt in our minds that pneumonia is an infectious disease, or that preventive measures must be used very much as for meningitis. All factors which weaken men and lower the vitality are powerful predisposing causes. Of these measles is the chief; it prepares the bronchii for receiving the germs, spreads the pneumococcus through bronchial cough, and in some peculiar manner renders the patient especially susceptible. It may be said to produce a sort of anaphylaxis for pneumonia.

PERSONAL

Major Harrold of the One Hundred and Twenty-First Infantry is out of the hospital after a severe operation. He left Thursday for a short trip to Washington.

BASE HOSPITAL

Major Cole, chief of surgical service at the base hospital, is using the Carrel method of wound treatment, with good results. He finds the Dakin solution rather difficult to prepare and preserve. Freezing makes it worthless. The treatment was demonstrated to all medical officers on Thursday. Major Sailer, chief of medical service, addressed the medical officers on the old but ever new subject, pneumonia, on Friday.

Room for better handling of patients has been made by the transfer of 123 pneumonia convalescents to Fort McPherson.

Mumps are on the increase judging from the admissions during the week.

Major Hans Zinsser gave a most interesting and instructive lecture on the serum treatment and diagnosis of the various types of pneumonia on Monday night. He is now actively engaged in locating and isolating meningococcus carriers of whom a few have been found in the division.

ONE HUNDRED AND SIXTH SANITARY TRAIN

Major Lorin A. Greene, commanding Field Hospital No. 121, has returned from his leave of absence and has taken up his duties with renewed vigor.

Lieutenant Stearns of Ambulance Company No. 122 has been transferred to the base hospital at this station for permanent duty.

The many friends of Lieut. Peter S. Mallon are pleased to hear that he is recovering from his serious illness at the base hospital at Fort McPherson.

The "big house" started last week by Majors Keenan and Patterson has been completed and occupied. The train commander and the director of field hospitals certainly seem comfortable in their three-room bungalow.

Recruiting has been brisk the past week and the Field Hospital No. 124 has practically completed its quota through the activity of Captain Miles.

Lieutenant Meriwether of Field Hospital No. 122 is on a short leave of absence.

Thirty-Fourth Division, Camp Cody, Deming, N. M.

BASE HOSPITAL

Dec. 12, 1917.

Associated with each division in mobilization camps is a base hospital, which, while not a part of the division, necessarily works in the closest cooperation with it, both in the care of the sick and injured and in the training of the personnel of the medical department. These hospitals are large, for they serve a population as great as that in our smaller cities. At Camp Cody, the base hospital has already a considerable history. This camp is not entirely new, but is over a year old, having come into being at the time of the trouble with Mexico, which led to the establishment of military camps at this and other places along the border. Ground within the town of Deming adjacent to the site of the camp was acquired by the Deming chamber of commerce and leased to the government for ninety-nine years at a nominal rate. Sewerage and water connections were given by the town council, and seven wooden buildings were erected, one for administration and six for use as medical and surgical wards. These were completed about August 1, and used for the hospital purposes under the direction of Major Truby, M. C., U. S. Army, first commanding officer of the base hospital.

Medical officers assumed command of the base hospital as follows: August 1, 1916, Major Truby; shortly afterward, Major F. W. Weed; December 1, Major M. H. DeLaney; April 17, 1917, Major H. C. Pillsbury; April 25, Lieut. (now Capt.) R. B. McLaws, and, Sept. 1, Major A. O. Davis, who is still in command.

With the advent of the Thirty-Fourth Division, the accommodations at the old base hospital became utterly inadequate, and the preparation of the new hospital was made part of the construction program. The site is 4 miles away from the noise and dust of the town, located in the full desert and affording an uninterrupted view of the mountains, which surround the Deming plain on all sides. Work was so far completed that, Nov. 1, 1917, all except the surgical patients were moved to commodious buildings ready for them. There are forty-three of these, built on the cottage plan, spread over a large area, but connected with one another by wide covered ways. These, and the spacious verandas surrounding the cottages, provide abundant opportunity for moving the sick and convalescent outdoors into the sunshine.

Twenty-two wards are occupied as follows: 1, measles and its complications; 2, 3, 6, 7, 8, 9, 10, 11, 13, 14, 15 and 16, medical wards; 4 and 5, genito-urinary wards; 12, pneumonias; 17 and 18, nose and throat cases; 19 and 20, orthopedic cases, and 21 and 22 (isolated) contagious diseases. Each ward accommodates forty patients, and there are in the hospital (December 6) 1,284 patients in the new hospital and 190 in the old. These include cases as follows; measles, 45; German measles, 192; pneumonia, 27; diphtheria, 3; scarlet fever, 8; venereal diseases, 16; tonsillitis, two wards; gastro-intestinal, one ward; awaiting possible discharge on surgeon's certificate of disability, 250. Thirty-three medical officers are in attendance and 311 enlisted man, Medical Department, including forty-five temporarily detached from the sanitary train. Major A. O. Davis, commanding officer, comes from Brighton, Maine; Major John W. Sluss of Indianapolis is adjutant; Major William H. Thomas of Philadelphia is chief of the surgical service, and Major Edward B. Bigelow of Worcester, Mass., of the medical service.

NOTES

French and British officers attached to the division are giving to the medical officers several talks on conditions on the west front. They are instructive and valuable, and are greatly appreciated.

Two divisional reviews have been held recently. Favorable comment was made on the character and conduct of the sanitary train.

The Thirty-Fourth led all the divisions in subscriptions to the Liberty Loan, having subscribed for a larger total and per capita amount than any other.

Over $7,000,000 in war insurance has been subscribed within the division thus far.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

Dec. 15, 1917.

Owing to the impassable roads following the deep snow, it was impossible for the garbage contractors to use their trucks for the collection of garbage, and it was found necessary by Dr. Luther R. Poust, sanitary officer, to operate the camp incinerator for garbage disposal. The various units were ordered to utilize their own wagons in hauling the garbage from their respective kitchens to the kitchens' garbage depot.

Freezing water pipes in bath houses have been one of the inconveniences suffered by the men at a few of the barracks. Active outdoor training has been retarded by the cold spell, and indoor lectures and classes have taken the place of drilling.

False reports of sufferings of soldiers at the cantonment and even stories of deaths from freezing have been circulated and branded as German propaganda. On the tenth instant, the second death from cerebrospinal meningitis occurred since the opening of the camp. Only a few days before he was taken sick, he took out a $10,000 War Risk Insurance Policy in favor of his mother. She will be the first beneficiary to receive payment on an insurance policy taken out at this post. There are twelve other meningitis patients at the camp, but all are expected to recover under the serum treatment. All company commanders have been authorized to waive Army regulations in cases of men honorably discharged from the service and without means to provide themselves with heavy outer clothing, letting them have overcoats to wear home. Overcoats issued are to be returned to the nearest Quartermaster's Depot within fifteen days after discharge.

The base hospital suffered considerable inconvenience by the freezing of water pipes leading to the operating room, putting out of commission all sterilizers. The commanding officers took personal charge of a group of men detailed to thaw out the pipes, and in a few hours the operating room was ready for an operation. Fortunately, during the period that it was out of commission not an emergency arose that required its use. Many oil stoves were requisitioned to heat wards after the steam was found inadequate.

BASE HOSPITAL

Special orders issued on the 13th, from Washington, D. C., direct Lieut.-Col. Will L. Pyle of the Medical Corps to report to the commanding general of the Eighty-Fourth Division, Camp Zachary Taylor, in person and assume charge of the base hospital. Colonel Pyle has been on duty at Fort Niagara, N. Y. He has not arrived as yet, and will relieve Major J. W. Worthington, who is the senior officer in charge of the base hospital, and who has been ordered elsewhere.

On the 13th, 906 cases were under treatment in base and regimental hospitals, against 967 earlier in the week. There are 23 cases of typhoid fever, 17 cases of pneumonia, 315 of measles, 7 of mumps, 5 meningitis carriers, 13 meningitis and 11 erysipelas. On the 14th, 63 patients were discharged.

Lieuts. S. H. Geist and Mayer are two of the busiest officers at the camp each morning up to 10 o'clock, as they are in the hospital receiving ward. An average of forty patients arrive at the hospital each morning, where they are examined and admission history taken before they are assigned to the wards.

"Walker," the ambulance dog, has been reported "absent without leave." The ambulance company has adopted another dog they named "Sergeant" so they may be able to throw food at him when displeased with the mess.

A company of the Three Hundred and Thirty-Fifth Infantry was due to be released from quarantine for meals when a private who had been exposed for seven weeks developed the disease, and all will have to remain in the confines of their area for fourteen days longer, thus destroying their chances for a furlough for Christmas. The patient is being accused of being the slowest mortal alive.

Eighty-Fifth Division, Camp Custer, Battle Creek, Mich.

DEC. 11, 1917.

Although winter weather has come down on us with its fury, the men seem to enjoy it. Training necessarily has been interfered with, yet hikes, drills and school work goes on much the same as if there were not 8 or 9 inches of snow on the ground.

Whether the cold weather will have any effect on the health of the camp remains to be seen; but reports given out by the division surgeon show the rate to be less than that of the general rate of the National Army, with only 14.79 per thousand. Thirty-two per thousand is the rate of the entire National Army.

The good work of the state health department, the city officials and the military police is without question responsible for the rather unusual percentage rate of venereal infections here. Camp Custer's record is only 1.75 per cent. As this includes all types, including those that were brought to camp with the draft increments, the showing is particularly gratifying to the division surgeon.

It has been shown that thirty-five female carriers of venereal infection were isolated and confined in hospitals at Ann Arbor. There has been no provision made for male carriers. It is expected that arrangements will be made by the state board of health for obtaining a building for segregation of civilian carriers.

The plan of instruction given the medical officers has been started again in paper work, gas defense work and map reading. The lyceum under the direction of Major Wood, commanding officer at the base hospital, has also begun, and much interest has been aroused by the interesting work planned by Major Wood. Every medical officer in camp is expected to attend these courses.

NOTES

Major George F. Suker, chief of the ophthalmic division of surgery of the head, addressed the Academy of Medicine at Kalamazoo, November 27, on "Injection of the Lateral Ventricles in the Treatment of Tabetic Optic Atrophy."

Major John Ridlon was again in camp, giving a course of instruction to the line officers on the care of the feet.

Eighty-Seventh Division, Camp Pike, Little Rock, Ark.

DEC. 9, 1917.

Camp Pike, in general with all southern cantonments, has just received a dose of the "Sunny South" that was entirely unexpected and unappreciated. The thermometer dropped to 2 degrees below zero, and there was a 6 inch fall of snow. The general style of architecture in the cantonment buildings is the same here as elsewhere, except that measures have been taken in northern camps to prepare for cold weather that have not been taken at Camp Pike. In the camps further north, the barracks have been lined with "compo" board, the foundations banked up and ventilators adjusted. At Camp Pike buildings are up on stilts, walls unlined on the inside, and ventilators open. It is a very difficult matter to make buildings of this type comfortable in zero weather, especially if there is a wind of considerable velocity blowing. These conditions are probably healthful and of no importance to robust individuals, but it is a matter for consideration as to the possible effect of such surroundings on persons either going through the period of incubation or recovering from certain contagious diseases. The conditions are ideal for the fresh air and cold air enthusiasts in the treatment of disease.

The state of health of the men in the division may be said to be very good. The base hospital at present is full, more than half of the patients having measles. There have also been scarlet fever and meningitis among some of the more recent arrivals from the North. Soldiers furnish about the same percentage of surgery as do individuals in civil life, so that this department is always reasonably busy.

The heating plant at the hospital has been completed, and the buildings are very warm and comfortable at present.

Major-General Gorgas visited the camp about December 1.

Colonel Chamberlin of the Surgeon-General's Office was also a recent visitor.

One of the problems confronting Camp Pike at the time of its construction was the matter of suitable sewage disposal. It was necessary to discharge the sewage into Five Mile Creek, a small stream in this vicinity. This formed a bubbling, fetid and offensive stream which flooded Bayou Meto and Trammel Lake and other swampy areas in this region. A sprinkling filter basin for all sewage has been constructed which renders the sewage inoffensive as far as odor is concerned.

The tuberculosis examination board, under the direction of Major Gath of Cincinnati, although it has been here several weeks, is still very busy. Lieutenant De Witt of this board, formerly a member of the medical officers' training camp at Fort Benjamin Harrison, has been promoted to a captaincy, as have also Lieut. Charles Lerrigo of Topeka in command of Ambulance Company No. 347, Three Hundred and Twelfth Sanitary Train, and Lieut. T. R. Ayres of St. Louis, at present with the regimental infirmary of the Three Hundred and Thirty-Fourth Field Artillery.

Some of the medical officers in this division who have recently taken advantage of a ten day leave of absence in order to visit their homes are: Major J. W. Thornton of Iowa, Capt. J. B. Steele of Tennessee, Capt. Paul R. Howard of Nebraska and Lieut. N. R. Palmer of Missouri.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

DEC. 12, 1917.

During the week just passed, the Eighty-Ninth Division was honored by a visit from Surgeon-General Gorgas and his party, which included Colonel Howard, M. C., Major Vaughan, M. R. C., of the University of Michigan Medical

School, and Dr. Welch of Johns Hopkins. They inspected the base hospital, the camp and its infirmaries, and all expressed themselves as highly pleased with the organization and work of the medical department in this division.

On the first evening of their stay, the Surgeon-General, Dr. Welch and Major Vaughan delivered a short address to all the medical officers of the camp. After extending remarks of greeting to all, the Surgeon-General directed his remarks particularly to the colored medical officers of the Ninety-Second Division. He stated that, as one born and raised in the South, who had watched with interest and appreciation the struggles of a newly freed race toward better things, he thought it particularly commendable that the colored physicians should have taken it on themselves and succeeded in volunteering their services in the Medical Department, in this greatest of all wars for democracy. He stated that he was sure they would give a good account of themselves, both as officers and as physicians.

Dr. Welch, who accompanied the party as epidemiologist, showed the typical modesty of a great man, when he told us that there was more for him to learn from the way the medical department of this camp was conducted than there was for him to teach us.

Major Vaughan stated that, while the division sanitary inspector and the division surgeon had been justly complimented by the two previous speakers, he wished, in addition, to extend his congratulations to the regimental surgeons and other medical officers of the camp who had made the work run smoothly. He said he was sure that all the sacrifices represented by the presence of the officers in the audience before him would be amply repaid in the years to come by the feeling that when their country needed them, they had responded to the call.

ORDERS TO OFFICERS OF THE MEDICAL CORPS

Major JUNIUS F. LYNCH, relieved at Camp McClellan, and *to Camp Stuart,* Newport News, Va., for duty.

Lieut. ROSSNER E. GRAHAM, relieved at Allentown, Pa. and *to Camp Lee,* Petersburg, Va., for duty.

Major ADDISON D. DAVIS, relieved at Camp Kearny, and *to Camp Joseph E. Johnston,* for duty as commanding officer of the base hospital.

Major HENRY J. NICHOLS, relieved from U. S. Army General Hospital No. 1, and *to Walter Reed General Hospital,* Takoma Park, D. C., for treatment.

Lieut.-Colonel WILLIAM E. VOSE, relieved from station at Fort Williams, Me., *to Fort McPherson, Ga.*

Colonel LEIGH A. FULLER, relieved at Fort D. A. Russell, and *to Charleston, S. C.,* to report in person to the commanding general, Southeastern Department, for duty as department surgeon.

Lieut.-Colonel WILLIAM L. LITTLE, relieved at Newport News, Va., and *to Fort Bliss, Texas,* for duty as division surgeon.

Major JESSE R. HARRIS, relieved at Fort Niagara, and *to Ithaca, New York,* Military School of Aeronautics, Cornell University, for duty.

Lieut. HENRY TIMROD SCHIFFLEY, relieved at Camp Sevier, and to report in person to the commanding general, 30th division, for duty in the base hospital.

Lieut.-Colonel JOHN W. HANNER, *to New York City* to command and mobilize Base Hospital No. 116, at the 71st Regiment Armory.

Capt. HERBERT R. DREARY, relieved at Camp McClellan, and *to his home* and honorably discharged from the Medical Corps of the National Guard.

ORDERS TO OFFICERS OF THE MEDICAL RESERVE CORPS

Alabama

To Camp Bowie, Fort Worth, Texas, base hospital, from Camp Meade, Lieut. GEORGE W. KIEHNHOFF, Daphne.

To Camp Funston, Fort Riley, Kan., as member of board for examination of command for tuberculosis, from Fort Worth, Lieut. SAMUEL E. JOHNSON, Clanton.

To Camp Travis, Fort Sam Houston, Texas, to examine the command for mental and nervous diseases, from Baltimore, Lieut. ROBERT H. HOWARD, Tuskegee.

To Fort Oglethorpe, for instruction, Capt. WALTER WILLIS ROSSER, Stevenson; Lieuts. WALTON L. BEAN, Andalusia; LEO C. WOODS, Birmingham; BURTON F. AUSTIN, Chancellor; Hospital Train No. 28 from Fort Oglethorpe, Lieut. ROBERT S. DODSON, Grand Bay.

To New York City, Base Hospital No. 116, for duty from Boston, Capt. PAUL L. COCKE, Birmingham; for instruction in orthopedic surgery, from Fort Ethan Allen, Lieut. DAVID RAMSEY, Pine Apple.

Arizona

To Army Medical School, Washington. D. C., for instruction in orthopedic surgery, from Fort Oglethorpe, Capt. RODERICK D. KENNEDY, Globe.

To New York City, Orthopedic Hospital for instruction in orthopedic surgery, from New York City, Capt. CHARLES T. STURGEON, Globe.

Arkansas

To Camp Beauregard, Alexandria, La., for duty, from Fort Smith, Lieut. WALTER G. EBERLE, Fort Smith.

To Camp Pike, Little Rock, Ark., for duty, from Camp Lee, Lieut. GUY A. McCORMACK, Little Rock.

To Fort Oglethorpe, Ga., for instruction, Lieut. ARTHUR F. HOGE, Fort Smith.

To Little Rock, Ark., to enlist the enlisted personnel of Hospital Unit "T," Capt. ALVIN L. JOBS, Little Rock.

To Walter Reed General Hospital, Washington, R. C., for observation and treatment, Lieut. TRUE S. BURGESS, Russellville.

California

To Camp Fremont, Palo Alto, Calif., base hospital, from Fort Mason, Capt. LOUIS P. HOWE, San Francisco.

To Camp Kearny, Linda Vista, Calif., for duty, Capt. CHARLES L. GARVIN, Los Angeles; Lieut. EDGAR O. CAMPBELL, Santa Barbara; base hospital, Lieut. HOWARD B. DIXON, Daly City; Lieut. CHARLES E. SCHWARTZ, San Francisco.

To Camp Lewis, American Lake, Wash., for temporary duty to examine the command in his specialty, Capt. WILFRED F. BEERMAN, San Francisco.

To Camp Taylor, Louisville, Ky., base hospital, from Fort Oglethorpe, Lieut. ELMER W. SMITH, San Francisco.

To Fort Mason, Calif., Base Hospital No. 30, Capts. HOWARD E. RUGGLES, San Francisco; CHARLES N. RICHARDS, San Jose; Lieuts. CLARK R. GILES, WILLIAM W. WASHBURN, JOHN H. WOOLSEY, San Francisco; from Camp Kearny, Capt. HERBERT S. THOMSON, Berkeley; Lieuts. ERNEST H. FALCONER; HAROLD W. WRIGHT, San Francisco; from Camp Lewis, Lieut. HUDSON SMYTHE, Stockton; from Camp Travis, Lieut. ARTHUR C. GIBSON, San Francisco; from San Francisco, Lieut. ELDRIDGE J. BEST, CHARLES L. TRANTER, San Francisco.

To Fort Riley, for instruction Capts. ROBERT M. JONES, Jr., Fresno; GORDON B. HAMILTON, Oakland; Lieuts. BERNARD SHELTON, Long Beach; ERNEST E. WILSON, Walnut Grove; with Evacuation Hospital No. 7, from Camp Cody, Lieut. LIVA C. McLAIN, Bakersfield.

To New York City Orthopedic Hospital, for instruction in orthopedic surgery, from New York City, Lieut. JOSEPH R. JONES, Yreka.

To his home and honorably discharged on account of being physically disqualified for active service, from San Diego, Capt. ALEXANDER PATTERSON, San Francisco.

Honorably discharged, Lieut. SOLOMON C. MISH, San Francisco.

Canal Zone

To Washington, D. C., for duty in Aviation Section, Signal Corps, from Mineola, Capt. EDWARD P. BEVERLY, Balboa.

Colorado

To Camp Custer, Battle Creek, Mich., as president of board for examination of command for tuberculosis, from Camp Bowie, Major GERALD B. WEBB, Colorado Springs; base hospital, from St. Louis, Lieut. FRED H. CARPENTER, Denver.

To Camp Doniphan, Fort Sill, Okla., base hospital, Lieut. RANULPH HUDSTON, Denver.

To Camp Joseph E. Johnston, Jacksonville, Fla., as a member of the board for examination of command for tuberculosis, from Camp Bowie, Lieut. PHILIP A. LOOMIS, Colorado Springs.

To Camp Mills, base hospital, from Camp Mills, Lieut. PHILLIPS M. CHASE, Denver.

To Fort Riley, for instruction, Lieuts. JOSEPH B. SALBERG, Boulder; CARLETON O. BOOTH, Denver; JOSEPH A. KELLY, Oak Creek.

Connecticut

To Fort Oglethorpe, for instruction, Capt. JOHN B. GRIGGS, Hartford; Lieut. EDWARD A. WILLIAMSON, Stamford.

To Fort Slocum, N. Y., for duty, from Fort Ethan Allen, Lieut. M. H. GRISWOLD, Kensington.

To Hoboken, N. J., for duty, from Washington, D. C., Capt. ARTHUR B. COLEBURN, Middletown.

To New York City, for instruction in orthopedic surgery, from Hartford, Lieut. HERMAN M. HURWITZ, Hartford.

To Philadelphia, Pa., for instruction in orthopedic surgery, Capt. ROBERT H. YERGASON, Hartford.

District of Columbia

To Fort Keogh, Montana, for duty, from Fort Snelling, Capt. HARRY L. SCHURMEIER, Washington.

To Fort Oglethorpe, for instruction, Lieuts. CHARLES F. BOVE, GEORGE W. MANNING, Washington.

To Hazelhurst Field, Mineola, L. I., N. Y., for duty, from office of the Chief Surgeon, Major EDWARD G. SEIBERT, Washington.

Honorably discharged, Lieut. TRUE S. BURGESS, Takoma Park.

Florida

To Fort Oglethorpe, for instruction, Capt. MURDOCH L. CRUM, Bowling Green; Lieuts. ROBERT D. MAY, HOWARD C. VON DAHM, Jacksonville; JOHN L. ADAMS, Milligan; GEORGE H. GWYNN, HUMPHREY W. GWYNN, Tallahassee; EUGENE S. GILMER, Tampa; HERBERT A. McCLURE, Walnut Hill.

To New York City, Post-Graduate Medical School for instruction, from Camp Greene, Capt. HARRY A. PEYTON, Jacksonville.

To his home and honorably discharged on account of being physically disqualified for active service, from Camp Meade, Lieut. HARRY C. GALEY, Key West.

Georgia

To Atlanta, Ga., to enlist the enlisted personnel of Base Hospital No. 43, Lieut. EDGAR H. GREENE, Atlanta.

To Camp Beauregard, Alexandria, La., base hospital, from Fort Oglethorpe, Lieut. EARL T. NEWSOM, Camilla.

To Camp Cody, Deming, N. M., base hospital, from Fort Oglethorpe, Capt. WILLIAM B. OREAR, Savannah.

To Camp Gordon, Atlanta, Ga., base hospital, Lieut. JOSEPH A. McGARITY, Draketown.

To Camp Logan, Houston, Tex., base hospital, Major THEODORE R. CERTEL, Augusta.

To Fort Bliss, Texas, with Headqurters Military Police, from Camp Greenleaf, Lieut. JESSE H. HENDRY, Shellman.

To Fort Oglethorpe, for instruction, Lieuts. LUTHER E. KELLEY, Atlanta; JESSE J. EVERETT, Campton; DENNIS F. WELDON, Danelsville; OSCAR S. SPIVEY, Eatonton; CLAUDE B. BROOKINS, Gordon; EUGENE F. THOMASON, Lumber City; WILLIAM T. RANDOLPH, Monroe; CHARLES B. UPSHAW, Rydal; WILLIAM M. WHITE, Watkinsville.

To Newport News, Va., for duty, from Fort Oglethorpe, Lieut. WALTER E. MOBLEY, Social Circle.

To New York City, Base Hospital No. 116, from Fort Riley, Capt. WILLIAM G. LEE, Macon.

To Philadelphia, Pa., for instruction in orthopedic surgery, Lieut. KENNETH S. HUNT, Milner.

To his home and honorably discharged from Fort Oglethorpe, Lieut. JOSEPH D. LYLE, Savannah.

Hawaii

To his home and honorably discharged from San Diego, Lieut. SAMUEL R. BARNES, Honolulu.

Idaho

To Fort Riley, for instruction, Lieuts. GEORGE B. RANDALL, Buhl; CLAUDE W. WILLIAMS, Laclede; JOHN C. WIIK, Moscow.

To Vancouver Barracks, Wash., for duty, from Camp Lewis, Lieut. FREDERICK W. DIDIER, Harrison.

Illinois

To Boston, Mass., Harvard Medical School, for instruction in orthopedic surgery, Lieuts. ROBERT W. KISPERT, Chicago; BENJAMIN J. SCHWARTZ, Waukegan.

To Camp American University, Washington, D. C., for duty, from Fort Sheridan, Lieut. KARL J. HENRICHSEN, Chicago.

To Camp Beauregard, Alexandria, La., base hospital, from Fort Oglethorpe, Lieut. IRA E. NEER, Springfield.

To Camp Gordon, Atlanta, Ga., base hospital, from St. Louis, Lieut. HUDSON McB. GILLIS, Woodriver.

To Camp Mills, Garden City, L. I., for examining the command in his specialty, Lieut. JOHN T. MacCURDY, Pembroke Lodge.

To Camp Wadsworth, Spartanburg, S. C., base hospital, from Fort Oglethorpe, Lieut. ABEL P. M. SANDALH, Chicago.

To Fort Bliss, Texas, with Headquarters Military Police, from Camp Greenleaf, Lieut. JAMES K. JOHNSON, Ellsworth.

To Fort Oglethorpe, for instruction, Lieut. FREDERICK H. MAURER, Peoria.

To Fort Riley, for instruction, Capts. WILLIAM S. BROWN, Cairo; FREDERICK A. FISHER, THOMAS J. O'MALLEY, Chicago; JOHN A. BORTZ, Nauvoo; WALTER L. HOUGHLAND, Peoria; Lieuts. ALEXANDER P. ROBERTSON, Alton; HALLEY A. SMITH, Antioch; ELVEN J. BERKHEISER, Aurora; FRANK J KOTALIK, Berwyn; FRANK A. ANDERSON, SAMUEL AXELRAD, EDWIN J. BARNETT, STEPHEN BIEZIS, BERNARD J. BOLKA, SYLVESTER A. BRENZA, CHARLES B. BROMBERG, HENRY CHRISTIANSEN, ROY E. CHRISTIE, FLOYD M. CLARK, HERMAN C. CLAYTON, LAZARUS COHLER, JOHN E. DAMRON, ABRAHAM L. DESSER, HARRY J. DWYER, VICTOR FINSAND, ULYSSES S. GEIGER, EARL W. GILROY, ELMER A. GUNDERSON, RUSSELL A. HENNESSEY, CARL B. HERRMANN, WILLIAM ISRAELSON, EDWARD J. JENKINSON, CARL J. JOHANNESSON, HENRY C. JOHNSON, ROBERT F. KNOLL, MIECISLAUS J. KOSTRZENSKI, THOMAS LAHNERS, EDWARD J. MacDONALD, FRANK MADLEC, JOHN E. McGUIGGAN, FRED McK. MILLER, MAYER A. NEWHAUSER, HARRY S. NORTON, JOHN F. OATES, HOWARD S. PERRY, WILLIAM J. PICKETT, CHARLES E. PITTE, HAROLD A. RAMZER, ABRAHAM R. RIMMERMAN, FRANK J. SCHICK, FRED F. SCHWARTZ, WILLIS I. SILVERSTEIN, HARRY S. SOLOMON, HENRY A. STAIB, Chicago; CHARLES L. KERRICK, Chrisman; WARREN C. BLIM, Crete; GEORGE O. DE MOSS, Cropsey; THOMAS C. McCLURE, Dahlgren; MELVIN L. HOLE, Danville; GILBERT F. HARRIS, Easton; LAWRENCE J. BERNARD, East St. Louis; CLYDE J. CHAMNESS, Elkville; ALEXANDER W. FORDYCE, Gilman; HARRY P. REUSS, Granite City; HERMAN C. KOCH, Harvard; HARRY A. MYERS, Joliet; GEORGE J. BRAND, Lafayette; EDGAR C. COOK, Mendota; WILLIAM H. EVANS, Murphysboro; KEITH T. MEYER, Oak Park; HUGH E. COOPER, Peoria; HARRY H. HANLY, Peoria; GEORGE W. KIMBALL, Stewart; HORACE M. FRANCIS, Woodstock; LEO V. GATES, Zeigler.

To Fort Robinson, Neb., for duty, Lieut. ALBERT N. MACKEY, Aledo.

To Fort Slocum, N. Y., for duty, from Fort Ethan Allen, Lieut. MAURICE L. PUFFER, Downers Grove.

To Milwaukee, Wis., for duty in the office of the attending surgeon, from Chicago, Lieut. CLAUDE H. OGDEN, Chicago.

To New York City, for instruction in orthopedic surgery, Lieut. IRWIN H. CUTLER, Chicago; from Chicago, Lieut. VINCENT W. KOCH, Chicago.

To Philadelphia, Pa., for instruction in orthopedic surgery, Capt. EDSON B. FOWLER, Evanston.

To St. Louis, Mo., Washington University, *for instruction* in Urology and Dermatology, from Fort Oglethorpe, Lieut. GEORGE W. BOWMAN, Ashley.

Honorably discharged, Capt. WALTER P. McGIBBON, Chicago.

To the inactive list, from Fort Benjamin Harrison, Lieut. IRVING A. PORGES, Chicago.

Indiana

To Camp American University, Washington, D. C., for duty, from Fort Benjamin Harrison, Lieuts. CLARENCE K. JONES, Indianapolis; GEORGE T. JOHNSON, Terre Haute.

To Camp Green, Charlotte, N. C., base hospital, from Roosevelt Hospital, New York City, Lieut. BROWN S. McCLINTIC, Peru.

To Camp Pike, Little Rock, Ark., base hospital, from Fort Oglethorpe, Lieut. MELCHERD H. KUTCH, Terre Haute.

To Camp Sevier, Greenville, S. C., base hospital, from Fort Oglethorpe, Lieut. SEWELL B. COULSON, Indianapolis.

To Camp Taylor, Louisville, Ky., as medical member of examining board and recruiting officer, from Fort Benjamin Harrison, Lieut. PAUL B. COBLE, Indianapolis; for duty, from Camp Custer, Lieut. PERRY C. TRAVER, South Bend.

To Chickamauga Park, Ga., for duty from Fort Benjamin Harrison, Lieut. CLAUDE D. HOLMES, Indianapolis.

To Fort Oglethorpe, for instruction, Capt. GEORGE T. WILLIAMS, Crawfordsville; Lieut. ANDREW F. GUGSELL, Ferdinand; from Houston, Texas, Lieut. MERTON A. FARLOW, Milroy; with Ambulance Co. No. 42, from Camp Custer, Lieut. ELTON L. TITUS, Indianapolis.

To St. Louis, Washington University, for instruction in urology and dermatology, *from Camp Grant*, Lieut. WARREN W. HEWINS, Evansville.

Iowa

To Fort Riley, for instruction, from Camp Dodge, Major CHARLES E. RUTH, Des Moines; Capt. BENJAMIN C. DYER, Ames; for instruction, Capts. MARK C. JONES, Boone; ALANSON M. POND, Dubuque; FRANK G. RHODES, Sioux City; Lieut. LOUIS B. AMICK, Millersburg.

Kansas

To Army Medical School, Washington, D. C., for duty, Lieut. GEORGE M. GRAY, Kansas City.

To Fort Riley, for instruction, Lieuts. SAMUEL N. MALLISON, Canton; CHARLES A. THOMAS, Edna; CHARLES S. FRY, St. George; ALBERT M. BROWN, Wichita.

To St. Louis, Washington University, for instruction in urology and dermatology, from Camp Taylor, Lieut. CLYDE M. ZINK, Wellington.

Kentucky

To Boston, Harvard Medical School, for instruction in orthopedic surgery, from Fort Oglethorpe, Lieut. JOHN W. STEPHENSON, Ashland.

To Fort Oglethorpe, for instruction, Major JULIAN P. McCLYMONDS, Lexington; Lieuts. EUGENE C. HARTMAN, Brandenburg; EARL M. CUTLER, SELMAR F. HAUSER, CLIFFORD N. HEISEL, THOMAS H. KELLY, Covington; HAVILAND CARR, Cynthiana; HARRY F. MANN, Demonsville; RICHARD R. SNOWDEN, Irvine; HYLAN H. WOODSON, Kirkmansville; HUNTER W. GINGLES, Kirksey; JOSEPH R. ALLEN, Langley; LYTLE ATHERTON, Livermore; EDWARD L. IRVIN, MARION E. PIRKEY, ISAAC L. WYATT, Louisville; JOHN R. PRYOR, Mayfield; GIDEON W. STONE, Middlesboro; FREDERICK K. BLAIR, Morehead; HARLAN G. CLAYPOOLE, Mt. Olivet; HOMER A. SUTTER, Newport; MILTON J. STERN, Paris; RAYMOND M. EVANS, Tompkinsville; NATHAN FELD, Winchester.

To Fort Thomas, Ky., for duty, *from Camp Dix*, Capt. JOHN L. PHYTHIAN, Newport.

To Lexington, Ky., to enlist the enlisted personnel of Base Hospital No. 40, Lieut. GEORGE H. WILSON, Lexington.

To his home and honorably discharged from Fort Oglethorpe, Capt. EDWARD W. FORD, Hartford.

Louisiana

To Camp Joseph E. Johnston, Jacksonville, Fla., base hospital, from Fort Oglethorpe, Lieut. ERNASTUS L. MILLER, Longville.

To Camp Pike, Little Rock, Ark., for duty, from Camp Pike, Lieut. HOWARD P. DOLES, Blanchard.

To Fort Oglethorpe, for *instruction*, Lieuts. HAROLD G. F. EDWARDS, Abeville; EDWARD E. ARCHIBALD, Alberta; RALPH P. EVANS, Alexandria; WALTER P. LAMBETH, Allendale; HOWARD P. DOLES, Blanchard; ALARIC C. WHITTINGTON, JOSEPH L. EWING, Dodson; EDWIN M. LEVY, Jackson; BROOKS C. GARRETT, Shreveport; PATRICK H. FLEMING, St. Martinville; JOSEPH M. GORTON, Waterproof.

To his home and honorably discharged, from Fort Oglethorpe, Lieut. OLIVER W. ALFORD, Bovalusa.

Maine

To Camp Wheeler, Macon, Ga., base hospital, from Harvard Medical School, Capt. WILLIAM C. WHITMORE, *Portland*.

To Fort Oglethorpe, for instruction, Lieuts. FREEMEN P. GLASON, GARDINER; ISAAC L. GORDON, Lincoln; WYVERN A. COOMBS, Westbrook; FRED E. WHEELER, West Paris.

To Fort Slocum, N. Y., for duty, from Fort Ethan Allen, Lieut CHARLES E. COOK, Jr., South Berwick.

Maryland

To Baltimore, Md., Johns Hopkins Medical School, from duty as contract surgeon, Lieut. LEWIS H. WEED, Baltimore.

To Camp Beauregard, Alexandria, La., base hospital, from Fort Oglethorpe, Lieut. JULIE R. ROLENSON, Baltimore.

To Camp Dodge, Des Moines, for duty, from Fort Des Moines, Major FRANK MARTIN, Baltimore.

To Camp Joseph E. Johnston, Jacksonville, Fla., as adjutant of the base hospital, from Camp Hancock, Lieut. IRVING K. LOVETT, Baltimore.

To Fort Oglethorpe, for instruction, Lieuts. CLAUDE C. KELLY, THEODORE S. MOISE, JOHN C. NORTON, CLARENCE M. REDDIG, HARRY E. WILSON, Baltimore; WILMER M. PRIEST, North East; HUGH R. SPENCER, Parkton; MILFERT W. MYERS, Taneytown.

To Fort Slocum, N. Y., for duty, from Fort Ethan Allen, Lieut. ANTONE C. SORENSEN, Baltimore.

To New York City, to inspect the Neurological School, then to Montreal, Quebec, Toronto, Ontario and Winnipeg, Manitoba, Canada, for duty and on completion to his proper station, Capt. CHARLES BAGLEY, Jr., Baltimore; for intensive training in his specialty, from Baltimore, Lieut. HENRY E. AUSTIN, Baltimore.

To Washington, D. C., for duty in Aviation Section, Signal Corps, from Millington, Capt. COMPTON WILSON, Friendship.

To his home and honorably discharged, Major A. COTTON, Baltimore.

Massachusetts

To Army Medical School, Washington, D. C., as professor of orthopedic surgery, Major ELLIOT G. BRACKETT, Boston.

To Boston, Mass., Harvard Medical School, for instruction in orthopedic surgery, Lieuts. EARLE M. HUSSEY, Fall River; GEORGE MOSSMAN, Westminster.

To Camp Beauregard, Alexandria, La., base hospital, from St. Louis, Lieut. CHARLES F. CANEDY, Greenfield.

To Camp Grant, Rockford, Ill., base hospital, Capt. JOHN BRYANT, Brooklyn.

To Fort Oglethorpe for instruction, Capt. NOEL E. GUILLET, Brookline; Lieuts. WILLIAM E. BROWNE, JAMES C. LEAVITT, Boston; CHARLES H. MERRILL, Lynn; EMIL U. DILLENBACK, Springfield.

To Hoboken, N. J., for duty, from Fort Myer, Lieut. EDWARD H. FRENCH, Boston.

To Morrison, Va., for duty, from Langley Field, Lieut. WILLIAM L. CONNERY, Springfield.

To New York City, Base Hospital No. 116, from Boston, Capt. SAMUEL W. ELLSWORTH, Boston.

To St. Louis, Mo., for instruction in urology and dermatology, Lieuts. ROBERT J. EVANS, Jr., JOHNSTON L. CHERESKIN, Springfield.

To his home and the inactive list on account of being physically disqualified for active service, Lieut. HILMAR O. KOEFOD, Boston.

Michigan

To Camp MacArthur, Waco, Tex., base hospital, from Harvard Medical School, Capt. CURTIS D. PILLSBURY, Ann Arbor.

To Camp Mills, Garden City, L. I., to examine the command in his specialty, Lieut. NICHOLSON W. PINTO, Kalamazoo.

To Camp Sheridan, Montgomery, Ala., base hospital, from Fort Oglethorpe, Capt. FRANK C. KINSEY, Grand Rapids.

To Fort Riley, for instruction, Capt. LOUIS N. YORKES, Elk Rapids; Lieuts. HAROLD B. MARKHAM, Marquette; WILLIAM E. ALLEGER, Pittsford; LEON W. MARTIN, Plainwell; from Ann Arbor, Lieut. GORDON H. BAHLMAN, Flint; from Camp Custer, Lieuts. SPENCER VAN BARNUM, Coloma; WESLEY A. GIFFIN, Deckerville; FRANK W. GOWDY, St. Joseph.

To Hoboken, N. J., for duty, from Camp Sherman, Capt. GRIFFITH A. THOMAS, Detroit.

To Jeffersonville, Ind., Depot Quartermaster, for duty, from Fort Oglethorpe, Lieut. CYRUS B. GARDNER, Alma.

To New York City, for instruction in orthopedic surgery, from Ironwood, Capt. EUGENE B. STEBBINS, Ironwood.

To St. Louis, Mo., Washington University, for instruction in urology and dermatology, Lieut. LELAND H. TOWER, Battle Creek.

Minnesota

To Camp Beauregard, Alexandria, La., base hospital, from St. Louis, Lieut. FLOYD W. BURNS, St. Paul.

To Camp Dodge, Des Moines, Ia., base hospital, from Minneapolis, Lieut. CHARLES E. CONNOR, Minneapolis.

To Camp Greene, Charlotte, N. C., for duty, from Fort Snelling, Lieut. ELMER H. LUTZ, St. Paul.

To Camp Lewis, American Lake, Wash., base hospital, Lieut. HARVEY M. SLATER, Minneapolis.

To Camp Upton, N. Y., to examine the command for mental and nervous diseases, from Ann Arbor, Lieut. FREDERICK P. MOERSCH, Minneapolis.

To Fort Riley, for instruction, Lieuts. FRANK J. ELIAS, Duluth; VERNE S. COBOT, JAMES N. DUNN, Minneapolis; CLARENCE A. RATHBUN, Rice; STEWART H. ANDERSON, Wells.

To Hoboken, N. J., for duty, from Fort Snelling, Capt. MARTIN LARSON, St. Paul.

To Minneapolis, Minn., to enlist the enlisted personnel of Base Hospital No. 26, Lieut. GORDON M. CLARK, Minneapolis.

To Philadelphia, Pa., for instruction in orthopedic surgery, Lieut. IVER F. SELLESETH, Glenwood.

To his home and honorably discharged from the Medical Reserve Corps on account of being physically disqualified for active service, from Camp Custer, Capt. FRANKLIN R. WRIGHT, Minneapolis.

Mississippi

To Army Medical School, Washington, D. C., for duty, Lieut. WALTER B. DODSON, Jackson.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

New Officers.—At the annual meeting of the Tehama County Medical Society at Red Bluff, Dr. Frank J. Bailey was elected president; Dr. Walter Gavey, vice president, and Dr. Frank L. Doane, secretary-treasurer, all of Red Bluff.

Personal.—Dr. Melvin L. Moore, Los Angeles, who has been ill at his home for several days, is convalescent.——Dr. Clelia D. Mosher, medical adviser of women at Leland Stanford University, Palo Alto, has started for France to engage in welfare work for the Red Cross.——Dr. Edith E. Johnson, Palo Alto, has succeeded Dr. Mosher as medical adviser to students.——Dr. George A. White, Sacramento, who has been ill for several weeks, is now reported to be convalescent.——Dr. Rexwald Brown, Santa Barbara, is reported to be in a critical condition at Johns Hopkins Hospital, Baltimore.

Popular Medical Lectures.—A course of popular medical lectures will be given at the Stanford University Medical School, during January, February and March. The schedule of these lectures is as follows:

January 4: "The Control of Vice Diseases Among Troops Through Civil and Military Cooperation," Colonel Louis M. Maus, U. S. Army.

January 18: "Surgery of the Present War," Dr. Leo Eloesser.

February 1: "Industrial Fatigue," Prof. E. G. Martin.

February 15: "Food Poisoning from Canned Goods," Dr. Ernest C. Dickson.

March 1: "Recent Experiences of a Medical Man in the War-Zone," Dr. William P. Lucas, Professor of Pediatrics, University of California.

March 15: "Circulation of the Blood," illustrated with moving pictures, Dr. Arnold A. D'Ancona.

CONNECTICUT

Personal.—Dr. Frederick C. Goldstein has succeeded Dr. Louis H. Wilmot as city health officer of Ansonia.——Dr. Seymour L. Spier, police surgeon of New Haven, who was operated on, November 30, is reported to be convalescent.

Medical Milk Commission Formed.—At the November meeting of the Bridgeport Medical Association, a medical milk commission was appointed, consisting of Dr. Charles N. Haskell, chairman, Dr. Walter Brown, Dr. Fessenden L. Day, C. E. Calvin and J. H. Bowdry. This commission will cooperate with the department of health in the supervision of certified milk to be sold in the state.

State Health Association Organized.—At a meeting of health officers and other men in Hartford, December 6, the Connecticut Public Health Association was organized, and the following officers were elected: president, Dr. Stephen J. Maher, New Haven, chairman of the state tuberculosis commission; vice president, Dr. Charles J. Bartlett, state bacteriology; secretary, Dr. Charles P. Botsford, Hartford, and treasurer, James A. Maher, Bridgeport. It was decided to organize subsidiary committees in each county of the state.

ILLINOIS

Smallpox.—There are said to be forty cases of smallpox in Hanover, Jo Daviess County, and the disease has also appeared in Elizabeth and Galena. The state board of health has the situation in hand.

Tuberculosis in Chicago.—As a result of the first accurate tuberculosis survey made in Chicago, Health Commissioner Robertson reports that there are between 60,000 and 70,000 cases of tuberculosis in the city.

Antitoxin Supply Cut Off.—Health Commissioner Robertson has received notice from the state health department to cut off the supply of diphtheria antitoxin on account of the appropriation for this purpose having been expended.

Personal.—Dr. Clara E. Hayes of the medical staff of the Peoria State Hospital has been appointed superintendent of the State Training School for Girls, Geneva.——Dr. Herman M. Adler, Chicago, criminologist of the state department of public welfare, is head of the Voluntary Mental Hygiene Consulting Commission, which was opened, December 17, at the Cook County Psychiatric Hospital.——Major Richard J. McDonnell, Chicago, has resigned as medical adviser of the One Hundred and Eighth Engineers.——Major Eugene G. Clancy, Chicago, has been made director of field hospitals of the division.

Voluntary Medical Units Ready.—A medical unit and an ambulance unit have been mustered into the state service. The first unit of the Medical Corps is headed by Major Charles E. Boynton, and consists of Capts. E. Stillman Bailey, and Hugh R. Scofield, and Lieuts. Adrian R. Karreman, Ralph R. Holmes, John G. Campbell, James L. Smith and William J. Timmer. The ambulance company is commanded by Capt. C. M. Price, and is assisted by Lieuts. Guy E. Beard, W. S. Hubbard and R. I. Humphrey. The ambulance unit was enlisted from the employees of the McCormick plant of the International Harvester Company, which donated the ambulance and equipment to the organization.

KENTUCKY

Social Service Exchange.—A social service exchange has been established by which there will be a coordination of the charitable agencies of Louisville cooperating. A large proportion of these agencies have already affiliated with the exchange. This exchange will prevent duplication of effort, facilitate relief and promote efficiency. The expenses will be borne by the Federation of Social Agencies.

New Appointments.—The following appointments have been made by the Board of Public Safety of Louisville: Dr. J. N. Sebastian, city physician, western district; Dr. W. W. Smith, sanitary inspector, eastern district; Dr. E. L. Whedbee, negro, sanitary inspector to look after the indigent negroes. Drs. Florence Brandeis and Annie Veech, medical inspectors of schools; Dr. L. A. Crutcher, sanitary inspector, western district.

LOUISIANA

Appointed to Sanitary Corps.—John Henry O'Neal, sanitary engineer for the state board of health, has gone into the Sanitary Corps and has already entered the service. He has been granted leave of absence from his duties on the state board of health during the continuance of the war.

New Society Meets.—At the annual meeting of the Orleans Parish Medical Society, held in New Orleans, December 9, a service flag was raised, the central star of which was in honor of Rudolph Matas, M. R. C., U. S. Army. The following officers were elected: president, Dr. Paul J. Gelpi, Jr.; vice presidents, Drs. Frank J. Chalaron, Hector E. Bernadas and Everard W. Mahler; secretary, Dr. Paul T. Talbot, and treasurer, Dr. Henry W. E. Walther.

Medical Examiners in Session.—The State Board of Medical Examiners concluded its session, December 1. In the reorganization of the board, Dr. Leon J. Menville, Houma, succeeds Dr. John G. Martin, Lake Charles, as president, Dr. Thomas E. Wright, Monroe, succeeds Dr. Stuart L. White, Ruston, as vice president, and Dr. Edmund D. Martin, New Orleans, was elected secretary, succeeding Dr. James A. Henderson, who is in the military service.

MARYLAND

Personal.—Dr. Lewis A. Griffiths of Upper Marlboro has been appointed by the President to be inspector of explosives for the state of Maryland. Dr. Griffiths has been a member of the state board of medical examiners for the past fourteen years and has also served on the state board of health.——Capt. Clarence B. Farrar of the Canadian Army Medical Corps, a former Baltimorean, who has been for the past two years in charge of a large hospital at Coburg for returned Canadian soldiers who have suffered from shell shock and various types of mental disorders as a result of the war, spoke at a special medical meeting in Osler Hall, Baltimore, on December 14.

MISSOURI

Honors Paid Dead Officer.—Memorial services were held at Kansas City recently in honor of Lieut. William E. T. Fitzsimmons, M. R. C., U. S. Army, Kansas City, the first American medical officer to be killed in France. The meeting was attended by the consuls of all the allied nations.

Personal.—Dr. J. Adolph Gandy, Valley Park, St. Louis County, while crossing the Frisco tracks, November 24, was struck by a train and seriously injured.——Dr. James C. Welch, Jefferson City, formerly physician at the State Penitentiary, who had been charged with bribery, was acquitted, November 24.——Dr. Robert F. Hyland, St. Louis, is under treatment at St. John's Hospital, St. Louis, on account of injuries received in a collision between his automobile and a motor truck recently.

NEW YORK

Grenfell in Rochester.—Dr. Wilfred T. Grenfell, Labrador, gave a lecture under the auspices of the Commonweal Club, Rochester, December 8.

New Officers for Academy.—At the annual meeting of the Elmira Academy of Medicine, December 5, Elliot E. Bush, Elmira, was elected president; Dr. Oscar J. Bowman, Horseheads, vice president; Dr. J. Lee Kinner, Elmira, secretary, and Dr. Abraham Lande, Elmira, treasurer.

New York City

New Hospitals Incorporated.—At a special meeting of the State Board of Charities, December 12, the applications for incorporation of the Carson C. Peck Memorial Hospital, Brooklyn, and the Mercy Hospital, at Cazenovia Park, Buffalo, were approved. A dispensary license was granted to the Greenpoint Hospital, Brooklyn, of the Department of Public Charities. Action on the application for the incorporation of the Hebrew Convalescent Home at 235 West One Hundred and Twentieth Street and for the institution planned by the Committee for the Care of Jewish Tuberculous was deferred.

Pediatricians Plan to Solve War Problem.—At the stated meeting of the Section on Pediatrics of the New York Academy of Medicine, December 13, the subject of malnutrition in schoolchildren was discussed. Dr. Henry Dwight Chapin, New York, read a paper entitled, "The National Danger from the Defective Development of Growing Children in Time of War," in which he presented statistics showing that malnutrition is greatly on the increase among the schoolchildren of New York. His conclusion was that there are 120,000 children suffering from malnutrition, or on the borderline, in the public and parochial schools of the city. A motion was carried providing for the appointment of a committee of pediatricians to investigate existing conditions in reference to malnutrition, to act in an advisory capacity in cooperation with other relief agencies working along similar lines, and to keep a record furnishing information as to what service the individual members of the section were prepared to contribute to the solution of this problem. The endeavor will be made to work out a plan of relief that may serve as a standard for other cities.

OHIO

Communicable Diseases.—Smallpox is reported to be epidemic in the village of Monroe and several outlying sections of Middletown, where about thirty cases have been reported. ——Schools, churches and lodge halls of Malinta have been closed on account of an epidemic of scarlet fever.——The smallpox epidemic at Tarlton is reported to be well under control.

Councillor District Meeting.—The annual meeting of the First Councillor District Medical Society was held in Cincinnati, December 5, under the presidency of Dr. William Kelley Hale, Wilmington. Dr. Francis M. Fitton, Hamilton, was elected president, and Dr. Eric R. T. Wachtman, Cincinnati, secretary-treasurer. The afternoon session was held in the newly completed medical school building of the University of Cincinnati.

Hospital Notes.—The state department of health has recommended that a tuberculosis hospital be established for Crawford, Wyandot, Seneca, Hancock and Wood counties. During 1916, 168 deaths were said to have occurred in this district from tuberculosis.——A conference was held in Columbus, December 6, between orthopedists of the state and the hospital commission regarding the policies to be adopted in the proposed State Hospital for Crippled Children in which they agreed that the hospital should start with a limited number of patients, that its service should be broadened slowly, and that patients after operation should be retained at the hospital for education to fit them for useful work thereafter.

Personal.—Dr. Edward J. Schwartz, for fifteen years health officer of Salem, has resigned to accept a position as director of communicable diseases in the state department of health. ——Dr. Julius H. Jacobson has resigned from the staff and board of St. Vincent's Hospital, Toledo.——Dr. Gertrude H. Transeau has passed an examination for assistant epidemiologist in the state department of health.——Dr. William H. Rabberman, Forest, froze both feet while answering a professional call, December 10.——Dr. William C. Marshall, district physician of Dayton, has resigned, and will locate in Selma.——Dr. Frank H. Williams, Portsmouth, has been appointed local surgeon of the Chesapeake and Ohio Railway, succeeding Dr. Orin W. Robe, Portsmouth, who has been called to the colors.——Dr. Rush R. Richison, Yellow Springs, has been appointed superintendent of the district tuberculosis hospital, Springfield.——Dr. Frank P. Corrigan, Cleveland, has started for his new post of duty in Chile, where he is in the employ of the Chilean Exploration Company.

Cincinnati

Public Health Officers Organize.—The Cincinnati Public Health Council was organized at the Cincinnati General Hospital, November 23, and health officer, Dr. John H. Landis, was elected temporary chairman.

Research Society Elects Officers.—At the annual meeting of the Cincinnati Research Society, Dr. Jacob L. Tuechter was elected president; Dr. Meyer L. Heidingsfeld, Cincinnati, vice president, and Dr. Raphael Isaacs, secretary.

Physicians Appoint Fund Trustees.—Dr. John H. Landis, president of the Cincinnati Academy of Medicine, November 12, appointed Drs. William D. Porter, Benjamin K. Rachford, J. Ambrose Johnston, Frank W. Langdon and John W. Murphy, trustees of the $5,000 which was subscribed recently for the benefit of Cincinnati physicians in the military service.

Personal.—Dr. Charles A. L. Reed, who has been seriously ill in Atlantic City with hemiplegia consequent on an infectious thrombosis, is reported able to be up and around. ——Dr. Oliver P. Holt has resigned as a member of the medical staff of the General Hospital.——Dr. Arthur C. Bachmeyer, superintendent of the Cincinnati General Hospital, has requested that his salary be reduced from $4,500 to $2,100 a year during the period of the war, as he is also in active service as a captain in the Medical Reserve Corps.

OKLAHOMA

Personal.—Dr. Francis B. Fite, Muskogee, has been appointed a member of the State Board of Education, to succeed himself.

Smallpox at Lawton.—The conditions at Lawton regarding smallpox and other communicable diseases are so acute that the chief surgeon of Camp Doniphan has sent a letter to the governor of the state asking him to immediately take steps to have Lawton quarantined from the state. The governor thereupon assigned state health officer Dr. J. W. Duke, Guthrie, and his assistant, Dr. Herbert V. L. Sapper, Oklahoma City, to go to Lawton and make a preliminary survey of the situation.

OREGON

Detention Home for Women.—Kelly Butte, the subjail, is to be made the detention quarters and hospital for women found to be suffering from venereal disease. The committee has recommended to the county commissioners that the hospitals be put in condition immediately for the detention and treatment of these women. The cost for the next six months is estimated at $10,000.

Personal.—Dr. William M. Campbell, Portland, has been commissioned major and chief surgeon of the Oregon National Guard.——Dr. Esther C. P. Lovejoy, Portland, who is at present serving in France, is reported to have been commissioned first lieutenant by the French government.——Dr. Earl Smith, Portland, has been appointed coroner of Multnomah County, succeeding Dr. Ferdinand H. Dammasch, resigned to enter the military service.

PENNSYLVANIA

Anniversary of Academy.—The twenty-second anniversary of the founding of the Harrisburg Academy of Medicine was celebrated, December 7, at the academy in connection with the Dauphin County Medical Society. The address of the evening was delivered by Major Charles A. E. Codman, Philadelphia, M. R. C., U. S. Army.

Personal.—Dr. Rollen L. Shinaberry, Scranton, was shot and seriously wounded, December 10, by a man believed to be of unsound mind.——Capt. Lauren C. Thomas, M. R. C., Latrobe, has been given an honorable discharge from the service on account of ill health.——Dr. John W. Luther, Palmerton, is reported to be seriously ill.——The house of Dr. James R. Gormley, Dutch Ridge, near Beaver, was destroyed by fire, December 5, and Dr. Gormley narrowly escaped death.

Philadelphia

Babies' Hospital Campaign.—December 11, a whirlwind campaign to raise $175,000 for the Babies' Hospital began, and, December 15, had totaled $92,520. On the fourth day of the crusade, the teams turned in $20,190.

Heroin Seized.—With an arrest in a house at Green and Sixteenth streets recently, 40 ounces of pure heroin were seized, the largest single seizure of narcotics ever made in this city. The man arrested is under $10,000 bail.

Dinner to Women Doctors.—The board of corporators and the faculty of the Woman's Medical College of Pennsylvania gave a dinner, December 7, in honor of three alumnae of the college who are about to sail for France. These are Drs. Marie K. Formad, Marry Getty and Laura Hunt.

Personal.—Dr. Elizabeth M. Moyer, Baltimore, addressed the Medical Society of the Women's Hospital of Philadelphia, December 17, on "Radium Therapy."——Dr. Bernard Kohn has been appointed temporary director of school medical instructors to fill that position during the absence of Dr. Walter S. Cornell, now major in the Medical Reserve Corps.

WISCONSIN

Physicians Appeal.—An appeal was filed in the circuit court, November 28, in the case of Drs. Frederick C. Gessner, William F. Becker, Herbert W. Powers and William F. Wegge, who had sued Milwaukee County for $275 each for expert witness fees. The appellants testified in an insanity case, and claimed fees of $50 a day each, but the county board estimated the value of their services at $4 a day.

Hospital Notes.—The health committee of the Milwaukee Society of National Defense has adopted resolutions urging the governor to include in the call for a special session of the legislature a bill permitting the merging of the Emergency and County hospitals.——In the campaign to raise $500,000 for the new Columbia Hospital, Milwaukee, more than half the desired amount has already been secured.——Dane County Anti-Tuberculosis Sanatorium, largely a gift from Dr. Charles H. Vilas, Madison, a member of the board of regents of the University of Wisconsin, was opened for patients, December 1. About $30,000 has been expended in this work, and the sanatorium consists of an administration and an infirmary building and two cottages, furnishing accommodation for thirty patients.——The Tri-County Tuberculosis Sanitarium for Ashland, Bayfield and Iron counties is now an assured fact, as they county board of Bayfield County has authorized an appropriation of $30,000, and the Iron County board one of $20,000 for the same purpose.

Personal.—Dr. George C. Ruhland, Milwaukee, health commissioner, who relinquished his office to accept army service, and who has been on duty at Fort Sill, Okla., has been honorably discharged, and will resume his duties, January 1. Dr. Lewis J. Daniels, health commissioner ad interim, relinquished the position as by previous agreement.——Lieut. Ladislaus Louis Adamkievicz, assistant surgeon, U. S. Navy, Milwaukee, was rescued when the United States destroyer *Jacob Jones* was sunk by a submarine.——Dr. Thaddeus D. Smith, Neenah, who was wounded in an air raid over an American base hospital in France a short time ago, is returning to America, invalided.——Dr. Peter J. Christofferson, Waupaca, was seriously injured by the overturning of his automobile, December 4.——The house of Dr. James Hittner, Seymour, was destroyed by fire, November 19, at a loss of $12,000, little more than half of which was covered by insurance.——Dr. Gilbert E. Seaman, Milwaukee, has been made chief surgeon of the Thirty-Second Division at Camp McArthur, Waco, Texas.

CANADA

Relief for the Blind.—According to Sir Frederick Fraser, superintendent of the School for the Blind, Halifax, N. S., a committee for relief work among those blinded in the recent disaster in that city has commenced. The situation is appalling, as there have been more than 210 persons blinded through the terrible explosion.

Hospital News.—Lieut.-Col. P. W. H. McKeown, Toronto, O. C. Kitchener Hospital, Brighton, England, has applied for six months' leave of absence, and will visit Ireland.——The board of consultants of the Canadian Hospitals Military Commission is inspecting the military hospitals in Toronto and vicinity. They were accompanied on their tour of inspection by Lieut.-Col. E. Stanley Ryerson, A. D. M. S., Toronto.——The organization of the new Canadian special hospitals in England is authorized as follows: Westcliffe Eye and Ear Hospital, Folkstone, 400 beds; King's Canadian Red Cross Hospital, Bursley Park, 300 beds; affiliated hospital, Clarence House, Roehampton, 106 beds.——From London, December 14, it is announced that Major Philip Burnett, Montreal, is appointed to command the Red Cross Hospital at Buxton, replacing Col. Frederick Guest, St. Thomas, Ont. Major Lewis R. Murray, Sussex, N. B., is to command Uxbridge Convalescent Hospital, replacing Lieut.-Col. William Webster, Winnipeg, Manit., who assumes command at Bramshott, replacing Major Henry E. Kendall, Halifax, N. S. Major Gilbert B. Peat, Andover, N. B., is to command the Patricia Hospital at Ramsgate, replacing Lieut.-Col. Alexander J. Mackenzie, Toronto, Ont., who assumes charge of the medical section at Ramsgate. Capt. J. Adrien Grenier, St. Tite, Que., is gazetted flying officer.

GENERAL

Urges Efficient Medical Education for Negroes.—At its annual meeting, held in Memphis, November 15, the Southern Medical Association adopted several preambles and a resolution pointing to the necessity of perpetuating and making more efficient negro medical education in the United States.

Rockefeller Foundation Budget.—The Rockefeller Foundation budget for war relief expenditures in 1918 will total $5,050,000, with a possible addition of $5,000,000. This budget was approved by the trustees, December 11. The proposed expenditure includes $3,345,000 for the work of the International Relief Board, $424,000 of which is for the use of the tuberculosis commission in France.

Fenger Memorial Fund.—The directors of the Fenger Memorial Fund announce that the sum of $500 has been set aside for medical investigation, the money to be used to pay a worker, the work to be done under direction in an established institution, which will furnish the necessary facilities and supplies free. It is desirable that the work should have a direct clinical bearing. Applications with full particulars should be addressed to Ludvig Hektoen, 637 South Wood Street, Chicago, before Jan. 15, 1918.

Seaboard Railway Surgeons Meet.—The twenty-second annual meeting of the Seaboard Medical Association of Virginia and North Carolina was held at Norfolk, Va., December 4-6, under the presidency of Dr. Kirkland Ruffin, Norfolk, Va. Kinston, N. C., was chosen as the next place of meeting, and the following officers were elected: president, Dr. Ira M. Hardy, Kinston, N. C.; vice presidents, Drs. William L. Harris, Norfolk, Va.; Henry W. Carter, Washington, N. C., and Philip St. L. Moncure, Norfolk, Va.; secretary, Dr. Clarence Porter Jones, Newport News, Va., and treasurer, Dr. George A. Caton, Newbern, N. C.

Correction.—In the discussion by Dr. Alfonso G. Castelli, New York, on the paper by Drs. Lewellys F. Barker and Thomas P. Sprunt, Baltimore, which appeared in The Journal, December 8, p. 1926, it is stated:

> "We may start with 0.1 gm. of iron arsenate in 1 c.c. of solution, to be administered every day, children and undersized patients accordingly, and the dose may be increased up to 0.7 gm."

This should be:

> "We may start with 0.01 gm. (1 centigram) of iron arsenate in 1 c.c. of solution, to be administered every day, children and undersized patients accordingly, and the dose may be increased up to 0.07 gm. (7 centigrams)."

Bequests and Donations.—The following bequests and donations have recently been announced:

The ambulance company of Major John A. Hawkins, stationed at Allentown, Pa., a donation of more than $4,000, raised by the Automobile Club of Pittsburgh and the Allegheny County Medical Society.

Alumni Association of Jefferson Medical College, a bequest of $10,000, by the will of Dr. Joseph M. Malatesta.

New York Post-Graduate Medical School and Hospital, $5,000, by the will of Cora V. R. Catlin.

Hahnemann and St. Luke's hospitals, Philadelphia, each $30,000, by the will of William H. Keim.

Michael Reese Hospital, to found two rooms in memory of his two daughters, in the Chicago Jewish Orphan Asylum, $1,000, and Chicago Home for Aged Jews, $1,000, by the will of Simon Florsheim.

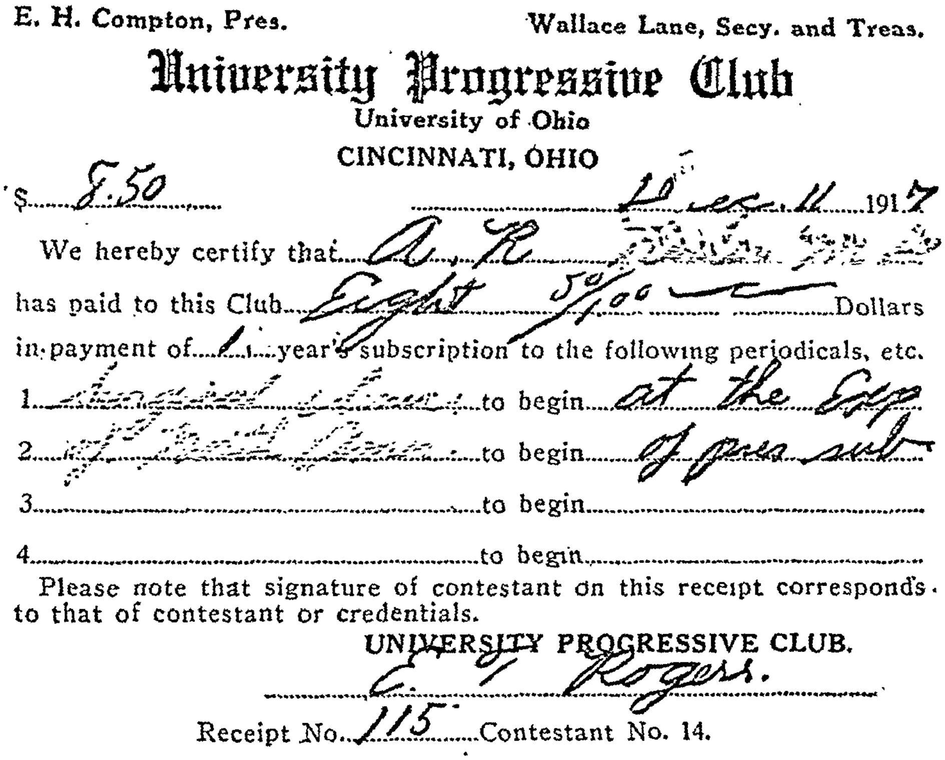
Philadelphia Home for Incurables, $1,000, and Home of the Merciful Saviour for Crippled Children, $300, by the will of Mary D. Day.

American Red Cross Commission, a donation of $250,000 for Italian wounded and needy refugees, by William K. Vanderbilt.

Presbyterian Hospital, Chicago, $10,000, by the will of Mrs. Mary R. Harris.

Chief of Bureau of Animal Industry Dies.—Alonzo Dorus Melvin, aged 55, chief of the Bureau of Animal Industry, Department of Agriculture, Washington, D. C., and the foremost figure of the government in combating foot-and-mouth disease and other diseases of cattle, died suddenly at his home in Washington, December 7, after a hemorrhage of the lungs. He was a native of Illinois, and a graduate in veterinary medicine from the Chicago Veterinary College in 1886. He at once entered the service in the United States Department of Agriculture, and transferred to Baltimore a year later. In 1890, he was sent to Liverpool to inspect animals and vessels from the United States, and two years later was placed in charge of the meat inspection in Chicago. He was made chief of the inspection division in 1895, and chief of the bureau, Dec. 1, 1905. Dr. Melvin was a member of the advisory board of the Hygienic Laboratory, U. S. P. H. S., was the president of the American Veterinary Association in 1909, and was an honorary associate of the Royal College of Veterinary Surgeons, London.

Once More a Warning.—Last week attention was called to a subscription swindle now being worked among physicians similar to a method worked at various times during the last few years. The individual presents himself as a contestant for a prize in the form of a scholarship to be awarded by an educational association to the one obtaining the most subscriptions during a certain period of time. It is worked under different names. We have called attention to it as the National Educational Association, the Cornell Educational Association, The United Students' Aid Society, and last week as the Advance Society of the University of Illinois. The latest form, the University Progressive Club of Cincinnati, is herewith reproduced.



E. H. Compton, Pres. **Wallace Lane, Secy. and Treas.**

University Progressive Club
University of Ohio
CINCINNATI, OHIO

$ 8.50 Dec. 11 1917

We hereby certify that A. R. [illegible]

has paid to this Club Eight 50/100 Dollars

in payment of 1 year's subscription to the following periodicals, etc.

1. [illegible] to begin at the Exp
2. [illegible] to begin of pres sub
3. to begin
4. to begin

Please note that signature of contestant on this receipt corresponds to that of contestant or credentials.

UNIVERSITY PROGRESSIVE CLUB.
Rogers.

Receipt No. 115 Contestant No. 14.

Form used by subscription swindlers. (*See item, "Once More a Warning."*)

Physicians should be on the watch for these swindlers, and should not pay money to agents whom they do not personally know.

LONDON LETTER

London, Nov. 20, 1917.

The War

DECREASE OF INSANITY

It is a curious fact, for which several explanations may be suggested, that during the war the number of the insane has decreased year by year. According to the returns for 1916, which have just been published, the number under care in England and Wales was 134,029, Jan. 1, 1917, as compared with 140,466, Jan. 1, 1915—a fall of 3,159 during the year 1916. If the average annual increase during the ten years previous to 1915 had been maintained, the number would have been 144,968—nearly 10,000 in excess of the number recorded. The relative sex percentages under care in 1916 were: males, 45.7, females, 54.3, against 46.2 and 53.8, respectively, in 1914. There were nearly 2,000 mental and nervous patients in the military hospitals, some of whom probably will eventually be certified as insane. This partly accounts for the disparity in the two sexes. Of the male attendants in the lunatic asylums, more than 50 per cent. have joined the army.

GERMAN HONORS RENOUNCED BY BRITISH SCIENTISTS

A note on membership of German academies and scientific societies has been circulated among the fellows of the Royal Society over the signatures of the following professors: Dr. W. M. Bayliss (physiology, University College, London); Sir James Dewar (experimental philosophy at Cambridge); Sir David Ferrier (neuropathology, King's College, London); Dr. J. N. Langley (physiology, Cambridge); Sir W. H. Perkin (chemistry, Oxford); Sir Ronald Ross (tropical sanitation, Liverpool University); Dr. C. S. Sherrington (physiology, Oxford); Dr. E. H. Starling (physiology, University College, London):

"The declaration of war by Germany against Russia and France was received with enthusiasm by practically every section of the German nation. The professors, who form the backbone of the German scientific academies and societies, were prominent as a whole in arousing this enthusiasm. It is largely due to them that a belief was created in German minds that Germany was superior to other nations, and that in consequence it was only just and right that German power over other nations should be extended. No German scientific academy or society has, so far as we know, issued any protest against the many infringements of humanity and of international law which have been characteristic of the German conduct of the war. The members of the Royal Society doubtless reprobate the action of the German government in bringing on the war, and its methods of conducting it, as much as any other section of British folk. It seems, therefore, incongruous that fellows of the society should continue to announce in the year-book of the society, in "Who's Who," or elsewhere, their membership of German academies and scientific societies as an honor which they value. It seems more consistent with the actual state of affairs that such mention should be omitted. Some fellows of the society have, we understand, already adopted this course with a view to bringing home to German scientific men that learning and research cannot be divorced from public conduct. Others with whom we have spoken intend to do so. Our occupations have prevented us from obtaining the opinions of the fellows generally, but as we believe that there is a widespread desire for common action, we venture to call attention to the matter. We intend to omit mention of German academies and societies."

A SPECIALIZED MEDICAL SERVICE FOR THE AIR FORCE

The establishment of the air force as an independent service instead of a branch of the army or navy, as it has been up to the present, is now arranged. Among the changes introduced is a specialized medical service. Flying men are subject to many peculiar physical disabilities, and research into the methods of prevention and cure has advanced very rapidly. So long, however, as the flying services remained merely as appendages of the army and navy, it was difficult to provide for their study and for the special treatment of the patient. Knowledge on the subject is limited almost entirely to those few medical officers and physicians who have had considerable numbers of flying men continuously under their care. It is necessary at once to take special measures to provide separate accommodation for the patients and a separate staff to concentrate on the problems that have arisen. The mere selection of candidates for the flying services has become a highly specialized business, and the standard of fitness required for flying is diverging from the standard required for the ordinary naval and military services. There are many minor physical imperfections which render a man unfit for flying, but which if treated early may be remedied. Still more important, many precautions have to be taken to enable pilots to maintain their fitness under the severe conditions of modern air warfare.

PARIS LETTER

Paris, Nov. 22, 1917.

The War

CHILLING OF THE FEET AS PREDISPOSING TO TETANUS

At a recent meeting of the Académie de médecine, Dr. H. Vincent, professor at the Val-de-Grâce Military Medical School, discussed the subject of tetanus provoked by frosting of the feet of the combatants. Vincent's experimental research has shown that if one injects the leg of a guinea-pig with tetanus bacillus spores, without the toxin, and then subjects the leg to cold and wet by means of continuous irrigation with water for two hours or more, tetanus develops, often acute or splanchnic. These experiments fulfil the etiologic conditions identical with those causing frosting of the feet in soldiers. Dry cold does not have the same effect. It is the prolonged maceration resulting from standing in the water in the trenches for many hours which is responsible for the chilling of the feet, the edema and the trophic disturbances. The tetanus bacillus spores get into the abrasions on the feet. Cold (15 C.—59 F., or below) annuls the phagocytic power of the leukocytes against the spores. The bacilli find a fertile culture medium in the edematous fluids as the tissues are warmed up, and the ultimate adsorption of this culture medium is equivalent to an injection of tetanus toxin. The symptoms of acute tetanus supervene in spite of prophylactic injections of antitetanus serum, no matter how potent it may be. The underlying tissues remain edematous for some days. The constriction caused by the leggings, which shrink under the influence of the imbibition of the water, favors the continuance of the edema, and hence the production of tetanus. It would be expedient, circumstances permitting, to empty the trenches of water, to loosen the puttee straps or use impermeable cloth leggings. Among the individual measures to be recommended, the most important is to wear large shoes, carefully greased or oiled, and woolen socks impregnated with grease containing some formaldehyd. The soldier should, whenever possible, remove his shoes for an hour or two, rub and dry his feet, and anoint them with some fatty substance. Men presenting the first symptoms of freezing, pains, etc., should be sent to a warm place near by where they can be treated by rubbing with alcohol.

RENOVATION OF COTTON COMING FROM MILITARY HOSPITALS

The Service de Santé (army medical department) uses enormous quantities of cotton. Paris alone uses at least 2,000 kg. a day. M. R. Villey, a chemist, has proposed to treat this soiled cotton so that it can be used again. The manipulation and transport of the cotton favors the dissemination of pyogenic organisms; hence certain precautions must be taken, notably to place at the disposition of the hospitals metal boxes that can be hermetically closed. The method of procedure is as follows: The hospitals sort out the cotton that is not too much soiled. The cotton which is wholly unfitted for further use is burned. The remaining cotton is conveyed, at regular intervals, to a designated place in town and from there to the sterilizing station, where it is subjected to a chemical treatment and transformed into absorbent cotton. It is important to free the cotton of all fatty substances which envelop the fibers like a greasy insulating sheath. To accomplish this result, the cotton is boiled for ten or twelve hours in soda lye, or, preferably, the cotton is autoclaved under pressure for about three hours, the steam containing a carbonate of soda lye. The cotton, freed of its fat sheath, is taken out of the autoclave, and is well washed in a tub provided with a strong paddle. It is then dried in a special turbine, which revolves very rapidly so as to remove all the moisture from the cotton. The product, well washed and dried, is placed in a calcium hypochlorite decolorizing bath, which bleaches the cotton to an immaculate whiteness. It is next washed thoroughly in water until free from the hypochlorite. After another drying, the cotton is carded, packed, and again autoclaved to insure perfect sterilization. As yet, only one sterilizing station has been equipped. It is situated at Montferrand, in the province near the Swiss border. About 20,000 kg. are treated daily. The soiled cotton is received from the central expediting hospital. The treated cotton is resold to the state at 1 franc 50 centimes (30 cents) per kilogram. In view of the fact that the price paid for cotton from America is 3 francs (60 cents) a kilogram or more, the saving to France amounts to more than 5,000,000 francs ($1,000,000) a year. Therefore it is contemplated to install sterilizing stations at Lyons, Mans, in the North, and in the Pyrenees.

Medical Instruction at the Front

In accord with the military authorities, M. Justin Godart, undersecretary of state for the military medical department, has organized, in the principal hospital centers in the army zones, courses for students of medicine, which will enable them to continue their studies and receive credits which may be presented for recognition later. The course is divided into two cycles, the first corresponding to the first and second years of the medical course, for which students will receive from two to eight credits. The second cycle corresponds practically to the third and fourth years of the medical course, and may be taken by students possessing nine to sixteen credits. The duration of each series is six months, three months being devoted to theory, with practical work, throughout the whole course in the center of instruction. The last course really is only three months' duration. Shortly, such courses will be given in each army, at the suggestion of the commander in chief himself, who desires to keep his younger medical officers as near at hand as possible. The courses are to be concluded by an examination held by the professors of each center and the civilian professors delegated by the various faculties. Failure postpones further work for six months, when the candidate is obliged to enter on a new course of study. The passing of the examination entitles the candidate to a diploma, which, at the close of hostilities, will be accepted as representing a certain number of credits, which entitle the candidate to cumulative credits.

Professional Training for Young Men with the Colors

The minister of public instruction has been impressed by the great danger to which the liberal professions are now exposed owing to the students and potential students being with the colors. It is to the best interests of the country that the professions be kept up under the most favorable conditions. Therefore, the minister has addressed a circular to the universities which authorizes them to register in the faculties and schools: (1) students who, following a war wound or disease contracted at the front, have been classified in the auxiliary service, and maintained in that position after thorough reexamination; (2) the reserve officers, serving with the fighting troops, who have been released from service, because of wounds or disease contracted at the front, and who are disqualified for further service; (3) the younger medical officers and pharmacists discharged for wounds or disease contracted at the front. These students will be permitted to register until December 1. When, by reason of their residence or of their service, it will be impossible for them to follow the regular course of study, they can ask for cumulative credits under the regular conditions. Thanks to this measure, they will be at liberty to resume their work as soon as their present situation will permit. The minister believes that this course of action is justified by the exceptional services they have rendered to the country, and that it is independent of the reparative measures that will be taken at the close of hostilities, and which will reestablish all possible equality between the young men who have pursued their normal course of study, and those who by the performance of their military duty have been temporarily diverted from their professional training.

Marriages

Lieut. Charles Snowden Pancoast, M. C., Pa. N. G., Philadelphia, to Miss Minnie Loretta Percell of New York City, in Philadelphia, November 28.

Lieut. Granville Inman Walker, M. R. C., U. S. Army, Savannah, Tenn., to Miss Katherine Welton of St. Paul, Ark., at Memphis, Tenn., December 2.

Lieut. John Christian Knapp, M. R. C., U. S. Army, to Miss Elizabeth Karsch, both of Philmont, N. Y., in New York City, November 12.

George Alvin Hughes, M.D., Cassopolis, Mich., to Mrs. Lenora Dennis of Edwardsburg, Mich., at Warsaw, Ind., November 29.

Jeremiah Alexander Klotz, M.D., Punxsutawney, Pa., to Miss Isabel Heimbach of Allentown, Pa., at Topton, Pa., November 22.

Asst. Surg. George Otis Cummings, U. S. Navy, Portland, Me., to Miss Sybil M. Kemp of Kingston, N. H., in Portland, November 25.

Harvey Alexander Price, M.D., Coquimbo, Chile, to Miss Marion Lenker of Mount Carmel, Pa., at Spring City, Pa., May 30.

Lieut. Webb William Weeks, M. R. C., U. S. Army, New York City, to Miss Ruth Thayer of Oklahoma City, December 2.

Robert Val Hoffman, M.D., Detroit, to Miss Eleanor Robbins Presstman of Baltimore, November 22.

Charles P. White, M.D., Wilmington, Del., to Miss Elizabeath B. Lobb of Philadelphia, November 28.

Neil Herbert Bailey, M.D., to Miss Florence Gertrude Long, both of Hartford, Conn., November 29.

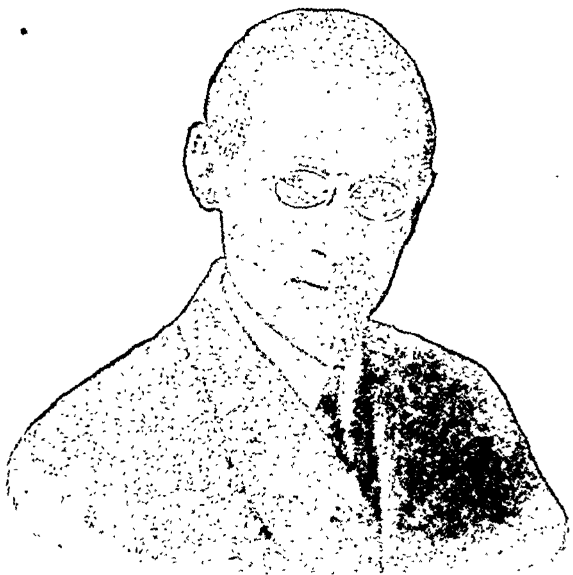
Deaths

Brig.-Gen. Bernard John Dowling Irwin, M. C., U. S. Army (retired); one of the most distinguished representatives of the Medical Department of the Army; aged 87; died at his country home, at Coburg, Ont., December 15. General Irwin was born in Ireland in 1830. He began the study of medicine in the Castleton (Vt.) Medical College in 1850, and later entered the New York Medical College from which he was graduated in 1852. After service as acting assistant surgeon, U. S. Army, for several months, he entered the Army as assistant surgeon, with the rank of lieutenant, and advanced through grades to Colonel and Assistant Surgeon-General, Aug. 28, 1890; was retired by operation of law, June 28, 1894, on attaining the age of 64, and was advanced to Brigadier-General (retired) by the act of April 23, 1904.

His service in the Army included numerous expeditions against the Indians, and he was awarded the Medal of Honor by Congress for "distinguished gallantry in action, Feb. 13-14, 1861." He was made medical director of the Army of Kentucky in 1862, and was captured in the battle of Richmond, Ky. After the close of the Civil War he served as post surgeon at a number of posts, chiefly in the West, and was attending surgeon, headquarters, Military Division of the Missouri, Chicago, from 1880 to 1882. He was in charge of the Army medical purveying depots in New York City and San Francisco until his promotion to colonel in 1890.

General Irwin devised the first field tent hospital for treatment of the wounded on the battlefield, at the time of the battle of Shiloh; its value was immediately recognized and it was promptly introduced into the military service, as the type of the most modern field hospital, and has since been adopted by the armies of all civilized nations.

Edward Augustus Ayers, M.D., Branchville, N. J.; New York University, New York City, 1880; aged 61; a Fellow of the New York Academy of Medicine, and a member of the Medical Society of the State of New York; emeritus professor of obstetrics in the New York Polyclinic; formerly a member of the New Jersey State Board of Health; founder and first president of the Mothers and Babies Hospital of New York; well known as a lecturer on scientific subjects; who won the Carpenter prize of the New York Academy of Medicine on "The Mosquito as a Sanitary Problem"; died in the Franklin (N. J.) Hospital, December 3, from pleuropneumonia.



Died in the Service

Capt. Augustin de Y. Green, M. R. C., U. S. Army, 1875-1917

(See The Journal, last week, p. 2059)

Ramon Guiteras, M.D., New York City; Harvard Medical School, 1883; aged 57; a Fellow of the American Medical Association; well known as a urologist; a member of the American Association of Genito-Urinary Surgeons, and American Urological Association; consulting surgeon to the French Hospital; visiting surgeon to the City and Columbus Hospital; professor of venereal and genito-urinary surgery in the New York Post-Graduate Medical School; well known internationally as a surgeon and big game hunter; died in the French Hospital, New York City, December 13, from meningitis.

William Allen Baker, M.D., Coloma, Mich.; Rush Medical College, 1882; a veteran of the Civil War; representative in the state legislature in 1887 and 1889; town supervisor; for several years justice of the peace, and for a number of terms president of the village of Coloma; promoter and builder of the railway from Coloma to Paw Paw Lake; builder and operator of the Coloma water works; died at his home, December 3.

George H. F. House, M.D., Indianapolis; Medical College of Indianapolis, 1879; aged 69; formerly a Fellow of the American Medical Association; a member of the Indiana State Medical Association; once vice president of the Marion County Medical Society; for one term president of the Indianapolis City Board of Health and Charities; died at the home of his daughter in Clayton, Ind., December 2, from cerebral hemorrhage.

Surg. Richard Bland Williams, Lieutenant Commander, U. S. Navy, Norfolk, Va.; University of Virginia, Charlottesville, 1898; aged 42; a Fellow of the American Medical Association; chief surgeon of the U. S. S. *Florida;* who entered the Navy, Nov. 17, 1900, as lieutenant, junior grade; while despondent on account of fear of losing his eyesight, is reported to have committed suicide in a hotel in Norfolk, December 5.

Edmund W. Meisenhelder, M.D., York, Pa.; Jefferson Medical College, 1868; aged 64; a Fellow of the American Medical Association, and a member of the staff of the York Hospital; a veteran of the Civil War; died suddenly from heart disease, while making a professional call, December 1. Tributes were paid to the memory of Dr. Meisenhelder at a meeting of the York County Medical Society, December 1.

Morris Norton Bemus, M.D., Jamestown, N. Y.; College of Physicians and Surgeons in the City of New York, 1889; aged 55; a Fellow of the American Medical Association, and of the New York Academy of Medicine; once president of the Medical Society of the State of New York, and of the Jamestown Medical Society; died at his home, December 9, from disease of the liver.

Mary Elizabeth Baldwin, M.D., Newport, R. I.; Women's Medical College of the New York Infirmary for Women and Children, 1874; aged 70; a Fellow of the American Medical Association; for twenty-five years secretary of the Newport Medical Society; died in a hospital in Brooklyn, from general toxemia following a nervous breakdown, November 21.

Edward Manning Brown, M.D., Springfield, Mass.; College of Physicians and Surgeons in the City of New York, 1898; aged 45; a member of the Massachusetts Medical Society and a specialist in dermatology and genito-urinary diseases; died in the Springfield Hospital, November 22, from meningitis consequent on an osteomyelitis of the skull.

Surg. Henry Albert Dunn, Lieutenant Commander, U. S. Navy, Philadelphia; George Washington University, Washington, D. C., 1897; aged 43; a Fellow of the American Medical Association; who was appointed an assistant surgeon and ensign in the Navy, June 7, 1900; died in a hotel in New York City, December 13, from heart disease.

Alice Byran Condict, M.D., Orange, N. J.; Chicago Homeopathic Medical College, 1883; Tufts College Medical School, Boston, 1906; aged 73; a Fellow of the American Medical Association; for more than a quarter of a century a medical missionary of the Presbyterian Board in India; died at her home, December 10.

John H. Hoxsey, M.D., Spokane, Wash.; American Medical College, St. Louis, 1885; aged 58; a member of the Washington State Medical Association; at one time physician to the Spokane County Poor Farm, and a member of the State Board of Medical Examiners; died at his home, November 29, from nephritis.

James Spencer Howard, M.D., Oswego, N. Y.; New York University, New York City, 1879; aged 80; for ten years surgeon to the Oswego City Hospital, and Oswego Orphan Asylum; a member of the board of health from 1908 to 1912; for several years jail physician; died in the Oswego Hospital, December 3.

Israel Cone Jones, M.D., New York City; Miami Medical College, Cincinnati, 1874; aged 67; a Fellow of the American Medical Association, and New York Academy of Medicine; since 1876 medical superintendent of the Home for Incurables, New York City; died in that institution, December 6.

Samuel Marcus Moore, M.D., Evanston, Ill.; Chicago Homeopathic Medical College, 1895; aged 47; a Fellow of the American Medical Association; from 1903 to 1914, chief surgeon of the Illinois Steel Company; died in the Greenwood Inn, Evanston, December 12, from pneumonia.

James E. Shannon, M.D., Sharon, Tenn.; University of Louisville, Ky., 1889; aged 52; formerly a Fellow of the

American Medical Association; a member of the Tennessee State Medical Association; died in St. Thomas Hospital, Martin, Tenn., December 1, from septicemia.

John Jay Sullivan, M.D., Passaic, N. J.; Albany (N. Y.) Medical College, 1890; aged 56; a member of the Medical Society of New Jersey; a specialist on internal medicine; died in Roosevelt Hospital, New York City, November 30, five days after an operation for gastric ulcer.

Hiram Beauregard Stout, M.D., Parkersburg, W. Va.; Medical College of Ohio, Cincinnati, 1899; aged 54; formerly a Fellow of the American Medical Association; a member of the West Virginia State Medical Association; died at his home, November 19, from arteriosclerosis.

Frank David Rieman, M.D., Paterson, N. J.; University and Bellevue Hospital Medical College, 1915; aged 33; a member of the visiting staff of the Isolation Hospital, and of the local board of school hygiene; died in St. Joseph's Hospital, Paterson, December 1, from pneumonia.

Herman F. W. Baltzer, M.D., St. Louis; University of Würzburg, Germany, 1875; aged 66; formerly a Fellow of the American Medical Association; a member of the Missouri State Medical Association; died in the Deaconess Hospital, St. Louis, October 17, from pneumonia.

John E. Bromwell, M.D., Mount Airy, Md.; University of Maryland, Baltimore, 1867; aged 77; formerly a Fellow of the American Medical Association; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, November 9, from arteriosclerosis.

Daniel P. Gerberich, M.D., Lebanon, Pa.; Hahnemann Medical College, Philadelphia, 1881; aged 62; state senator from Lebanon County for two terms, and once president pro tem of the state senate; died at his home, November 29, from the effects of a fracture of the hip.

Daniel B. Summers, M.D., Shelby, Ohio; Pulte Medical College, Cincinnati, 1888; aged 54; a member of the Ohio State Medical Association; died at his home, November 30, from the effects of a gunshot wound, self-inflicted, it is believed, with suicidal intent.

William Merrick Semans, M.D., Delaware, Ohio; Miami Medical College, Cincinnati, 1887; aged 55; formerly a Fellow of the American Medical Association; a member of the Ohio State Medical Association; died at his home, December 5, from arteriosclerosis.

Sylvanus Chase Curran, M.D., Yonkers, N. Y.; Albany (N. Y.) Medical College, 1885; aged 71; for ten years captain of the Twenty-Third Separate Company, N. G., N. Y.; died in the home of his daughter in Yonkers, November 21, from cerebral hemorrhage.

William H. Wills, M.D., Milford Center, Ohio; Starling Medical College, Columbus, Ohio, 1879; aged 57; a member of the Ohio State Medical Association; died at his home, November 27, from injuries received in an automobile accident the day before.

Denis W. Barry, M.D., San Pedro de Madoris, Dominican Republic; Yale University, New Haven, 1884; aged 55; formerly a practitioner of Brooklyn and of Pretoria, South Africa; died in the Skene Sanitarium, Brooklyn, December 6, from pneumonia.

Sallie Justina Ermentrout, M.D., Eldridge, Calif.; Women's Medical College of Pennsylvania, Philadelphia, 1891; aged 60; a Fellow of the American Medical Association; a member of the staff of the Eldridge State Hospital; died at her home, November 21.

Adolphus Henry Carter, M.D., Wiggins, Colo.; Northwestern Medical College, St. Joseph, Mo., 1892; aged 67; formerly a Fellow of the American Medical Association; for many years a practitioner of Salt Lake City; died recently at his home.

William Alder Smith, M.D., Galena, Ill.; Northwestern University Medical School, Chicago, 1897; aged 45; a member of the Illinois State Medical Society; died at Council Hill, Ill., November 17, from asthma associated with heart disease.

Mark W. Bynum, M.D., Brownwood, Texas; University of Pennsylvania, Philadelphia, 1857; aged 82; once physician of Brown County, and president of the Brownwood District Association; a Confederate veteran; died at his home, November 28.

Jackson Walker, M.D., Bethany, Mo.; University of Michigan, Ann Arbor, 1867; aged 81; formerly a member of the Missouri State Medical Association; a veteran of the Civil War; died at his home, November 18, from cerebral hemorrhage.

George Abbott Campbell, M.D., Manchester, N. H.; Boston University School of Medicine, 1881; aged 60; for the last twenty years a florist and proprietor of the Ray Brook Gardens; died in a hospital in Manchaster, about December 2.

Oliver A. Collins, M.D., Mohawk, Ind.; Medical College of Indiana, Indianapolis, 1886; aged 54; formerly a Fellow of the American Medical Association; a member of the Indiana State Medical Association; died at his home, December 30.

George Leiter Greenawalt, M.D., Fort Wayne, Ind.; Bellevue Hospital Medical College, 1880; aged 66; a Fellow of the American Medical Association, and a widely knowly surgeon; died at his home, December 6, from cerebral hemorrhage.

Isaac B. Malcolm, M.D., Lowell, Mich.; American University of Pennsylvania, Eclectic, Philadelphia, 1867; aged 72; one of the earliest practitioners of Kent County; died suddenly on the street, November 21, from heart disease.

Thomas Jefferson Powell, M.D., Childersburg, Ala.; University of Maryland, Baltimore, 1866; aged 76; formerly a member of the Medical Association of the State of Alabama; died at his home, November 23, from angina pectoris.

James Walsh Southworth, M.D., Glasgow, Mo.; New York University, New York City, 1862; aged 79; assistant surgeon of the Eighth New Hampshire Volunteer Infantry, during the Civil War; died at his home, about November 21.

Henry L. Porter, M.D., Seneca, Mo.; Homeopathic Medical College of Missouri, St. Louis, 1880; aged 68; a Fellow of the American Medical Association; died in a hospital in St. Louis, November 15, after a surgical operation.

John M. Woodburn, M.D., Boise, Idaho; Jefferson Medical College, 1881; aged 58; formerly a member of the Idaho State Medical Association; died in a hospital in Boise, November 28, from acute dilatation of the heart.

William Gibson McClumphy, M.D., Moundsville, W. Va.; Starling Medical College, Columbus, Ohio, 1882; aged 67; a member of the West Virginia State Medical Association; died at his home, November 26, from malaria.

Clarence Morgan Kurtz, M.D., Reading, Pa.; Jefferson Medical College, 1886; aged 56; a member of the Medical Society of the State of Pennsylvania; died suddenly at his country home, Old Ferry, Pa., November 25.

Emmett Burr Daley, M.D., Bennington, Vt.; New York University New York, 1879; aged 62; a member of the Vermont State Medical Society; died in the Samaritan Hospital, Troy, N. Y., October 10, from acute nephritis.

Harry Alta Andrews, M.D., San Francisco; Cooper Medical College, San Francisco, 1891; aged 48; formerly a member of the Medical Society of the State of California; died at his home, August 22, from cerebral embolism.

Lafayette D. Fuller, M.D., Rockville, Conn.; Eclectic Medical College of Pennsylvania, Philadelphia, 1867; aged 73; a medical cadet during the Civil War; died in his apartment, December 6, from cerebral embolism.

Harry Hallock Lente, M.D., Oldtown, Me.; Bowdoin Medical School, Brunswick and Portland, Me., 1912; aged 31; a member of the Maine Medical Association; died at his home, about November 3, from meningitis.

William Frederic Boes, M.D., Brooklyn; Long Island College Hospital, Brooklyn, 1892; aged 64; a member of the Medical Society of the State of New York; died at his home, November 27, from arteriosclerosis.

Robert Eugene Cato, M.D., Americus, Ga.; Jefferson Medical College, 1886; aged 57; a Fellow of the American Medical Association; died at his home, in Reese Park, Americus, November 26, from heart disease.

Richard Leonard Eldredge, M.D., Bonfield, Ill.; College of Physicians and Surgeons, Chicago, 1903; aged 51; a Fellow of the American Medical Association; died in Minooka, Ill., November 29, from pneumonia.

Elias B. Mesirow, M.D., Chicago; College of Physicians and Surgeons, Chicago, 1894; aged 56; formerly a Fellow of the American Medical Association; died at his home, December 10, from lobar pneumonia.

Gilmore Robert Stevenson, Hubbard, Ohio (license, Ohio, years of practice, 1896); aged 79; for fifty-one years a practitioner; a veteran of the Civil War; died in the Youngstown (Ohio) Hospital, December 2.

Margaret Enort Colby, M.D., Berkeley, Calif.; Northwestern University Woman's Medical School, Chicago, 1884;

aged 62; formerly a practitioner of Clear Lake, Iowa; died at her home, December 10.

David Cleveland Gordon, M.D., Washington, D. C.; Jefferson Medical College, 1856; aged 81; a veteran of the Civil War; a clergyman of the Protestant Episcopal Church; died at his home, December 1.

David Ashby Kincaid, M.D., South Portland, Me.; Bowdoin Medical School, Brunswick and Portland, Me., 1878; aged 63; formerly a member of the Maine Medical Association; died at his home, November 29.

Aloysius Kesseler, M.D., New York City; New York University, New York City, 1877; aged 74; formerly a member of the Medical Society of the State of New York; died at his home, November 30.

James A. Phillips, M.D., Morristown, N. Y.; Albany (N. Y.) Medical College, 1865; aged 80; for forty-eight years a practitioner of Morristown; died at the home of his son in Syracuse, November 28.

Henry Chorley Watt, M.D., Colorado Springs, Colo.; licentiate of the Apothecaries' Society of London, 1875; aged 45; a member of the Colorado State Medical Society; died at his home, December 1.

Nathaniel Babcock Darling, M.D., Brooklyn; College of Physicians and Surgeons in the City of New York, 1873; aged 83; also a pharmacist; died at his home, November 28, from arteriosclerosis.

Franklin Clark Terrill, M.D., Big Rapids, Mich.; University of Michigan, Ann Arbor, 1879; aged 68; a member of the Michigan State Medical Society; died at his home, December 4, from carcinoma.

John Francis McCooey, M.D., Woonsocket, R. I.; College of Physicians and Surgeons, Baltimore, 1903; aged 37; died in St. Vincent's Hospital, Worcester, Mass., December 1, from peritonitis.

James Louis Beyea, M.D., New York City; New York Homeopathic Medical College, 1880; aged 80; a veteran of the Civil War; died in the Flower Hospital, New York City, December 4.

Joseph de la Cruz de Varona, M.D., New York City; Bellevue Hospital Medical College, 1865; aged 74; died at the home of his brother in New York City, November 30, from influenza.

Richard West Bourne, M.D., Mexico, Mo.; Jefferson Medical College, 1848; aged 97; the first mayor of Mexico, elected in 1856; died at the home of his daughter in Mexico, November 23.

Charles James Allen, M.D., Sheffield, Iowa; Rush Medical College, 1887; aged 61; died at his home, August 31, from tuberculosis.

Quintus L. Adams, M.D., Philadelphia; Jefferson Medical College, 1888; aged 51; died at his home, November 27, from pneumonia.

Henry A. Crawshaw, M.D., Bush, Ill.; St. Louis College of Physicians and Surgeons, 1895; aged 47; was instantly killed in an automobile accident at Carbondale, Ill., November 7.

Isaac Riley Bucher, M.D., Lebanon, Pa.; Pennsylvania Medical College, Philadelphia, 1857; aged 85; died at the home of his son in Lebanon, November 23.

Albert Charles Nussle, M.D., Chippewa Falls, Wis.; University of Illinois, Chicago, 1908; aged 33; was accidentally drowned, October 14.

Thomas J. S. Kimbrough, M.D., Weatherford, Texas; University of Nashville, Tenn., 1870; aged 74; died at his home, September 28, from nephritis.

Henry D. Jones, M.D., Grand Marais, Minn.; Eclectic Medical College of the City of New York, 1878; aged 82; died in East Chatham, N. Y., August 21, from senile debility.

A. T. Hagemeyer, M.D., Youngstown, Ohio; Medical College of Ohio, Cincinnati, 1886; aged 58; was found dead in bed, November 30.

J. Abraham Wilson, M.D., Billings, Mo.; University of Tennessee, Nashville, 1885; aged 82; died at his home, October 17, from arteriosclerosis.

A. W. H. Wullschleger, M.D., Reno, Nev.; University of Zurich, Switzerland, 1902; aged 38; died at his home, October 11, from edema of the brain.

R. H. White, Cabot, Ark. (license, Arkansas, 1903); aged 57; a practitioner since 1893; died in Jacksonville, Ark., in September, from tuberculosis.

Davis Boswell, M.D., Beatrice, Neb.; Rush Medical College, 1888; aged about 70; died in Birmingham, Ala., November 24.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

TIMES-PICAYUNE THROWS OUT MEDICAL FRAUDS

Accepts Only Medical Advertisements That Have Been Investigated and Passed on by State Board of Health

About four years ago The Journal commented editorially on the rules which the New Orleans *Item* then put into effect governing the acceptance of medical advertising. These rules, while not binding the *Item* to reject all "patent medicine" advertising, did call for the rejection of such as was plainly fraudulent or was, after rigid scrutiny, open to suspicion. As the managing editor of the *Item* wrote at the time: "Practically the whole business will go out on October 1. I am frank to say that I did not know how bad it was until I had it collected and began to look at it in a critical way." The *Item* was fortunate in having connected with its staff a physician who aided in drawing up its rules and, more important yet, in interpreting and applying these rules.

Within the last month or two another New Orleans paper —the *Times-Picayune*—has made a decision with reference to the acceptance of medical advertisements that is, if anything, more far reaching than that made by the *Item*. The *Times-Picayune* is going to follow the standards for medical advertising set by the National Vigilance Committee of the Associated Advertising Clubs of the World. These standards are practically identical with the recommendations in the report issued about two years ago by the Commission on Proprietary Medicines that was appointed by the American Pharmaceutical Association. The *Times-Picayune* explains how it is going to be in a position to follow these standards:

> "In order that these rules might be fully maintained, it obtained the cooperation of Dr. Oscar Dowling, president of the Louisiana State Board of Health, to see that they were strictly lived up to, agreeing not to print any medical advertisements without first receiving the approval of the Louisiana State Board of Health. Sept. 1, 1917, the Louisiana State Board of Health undertook the work for the *Times-Picayune*.
>
> "This set another precedent in leadership for the *Times-Picayune*, as it was the first newspaper in the South, and probably anywhere in the country, to take such an advanced step. Censorship by the State Board of Health means that every medical advertisement now appearing in the *Times-Picayune* has been thoroughly investigated and passed upon by the State Board of Health."

The new policy of the *Times-Picayune* has been officially endorsed in resolutions adopted both by the Southern Medical Association in recent annual convention and by the Orleans Parish Medical Society at a meeting held November 26. Nor is the New Orleans *Item* backward in extending its congratulations to its competitor contemporary. This paper, in a recent discussion of "patent medicine" frauds and the nostrum evil generally, said:

> "Our competitor, the *Times-Picayune*, has recently joined the ranks of newspapers which recognize this evil. It now refuses to accept money for advertising medicines whose advertising is not approved by the Louisiana State Board of Health. The president of this board, Dr. Oscar Dowling, has taken a brave, a creditable and, we believe, a highly intelligent stand against these frauds. It is with sincere pleasure that we note the stand taken by the *Times-Picayune*. When it is borne in mind that the amount of advertising of this class runs into tens of thousands of dollars a year, it will be appreciated that our contemporary is sacrificing large revenue for correct principle."

Louisiana is one of the few states that have made any serious effort to curb the evils of quackery and "patent medicine" frauds. Its work in this direction and the growth of public opinion as reflected in the action of two of its most influential newspapers is undoubtedly due to the fact that the state has in its chief health officer an aggressive and uncompromising foe of fraud.

Correspondence

ENLARGEMENT OF LINGUAL TONSIL IN WHOOPING COUGH

To the Editor:—Last week I had called to my attention again a condition which I have noticed in whooping cough and of which, so far as I have been able to find out, there has been no mention made. For a few years back I have been examining all the patients with whooping cough that I have seen, and I find an inflammation and enlargement of the lingual tonsil in practically every case. Since April, 1914, I have examined forty-three cases and in all but one there was this same finding in connection with other throat symptoms. It has been decidedly more prevalent than any other one condition in the throat, with the possible exception of an acute pharyngitis.

Through The Journal I should like to ask other physicians to examine for inflammation of the lingual tonsil in their cases of whooping cough, because if this is a constant condition in this trouble, I believe it possible to work out a more rational treatment for this cough than we have had.

W. M. Ruckle, M.D., Grand Rapids, Wis.

"PRAYERS FOR PROFIT"

To the Editor:—An item headed "Prayers for Profit" in The Journal for June 9 has come to my attention. Its occasion is The Journal's satisfaction over the recent defeat of a proposed amendment to the laws of Ohio legalizing spiritual healing.

Permit me to correct the statement which it contains, that "it is well known" that Christian Science practitioners treat their patients "for the profit there is in it." It is not well known for it is not true, neither is there evidence on which to base the charge, nor the allied charge that the church is "evidently commercial." On the contrary, Christian Scientists are well known to their neighbors throughout the world to be an honest and conscientious body of people not given to charlatanism of any sort.

But the criticism of The Journal manifestly arises, neither from the fact that Christian Scientists are paid for their healing ministrations, nor from a supposed variation from the practice of Jesus, but from the fact that The Journal disapproves of the healing effort of Christian Science. Indeed, it evidently regards all spiritual healing as inimical. The evidence of this is supplied by the fact that the section which it was proposed to add to the Ohio Medical Practice Act, and over the defeat of which The Journal rejoices, reads as follows: "Nothing in this chapter shall be construed to apply to or interfere in any way with the practice of those who endeavor to prevent or cure disease or suffering by spiritual means or prayer."

It is evident, therefore, that while The Journal refers with approval to Jesus and his practices, it nevertheless believes in interfering with healing by spiritual means or prayer.

In these circumstances it may not be out of place to remind your readers that Jesus could not have passed the examination in materia medica which is properly required of those preparing to administer material remedies, but this fact did not prevent him from earning the title of "the Great Physician."

Avery Coonley, Chicago.

[Comment.—The item to which Mr. Avery Coonley takes exception—Mr. Coonley, it will be remembered, is the "Christian Science Committee on Publication for the State of Illinois"—was a brief editorial comment to the effect that the Christian Science Church is said to have among its followers no scientist recognized by men of science, no biblical authority recognized by biblical students, no man of standing in the world of philosophy and no physician of standing among medical men. It further commended the attitude of the state of Ohio for not granting the Eddyites who would treat the sick exemption from the educational requirements of the Medical Practice Act of that state.

Mr. Coonley's statement that "Jesus could not have passed the examination in materia medica which is properly required of those preparing to administer material remedies" might be true if Christ is conceived as a man without the powers of divinity. It is equally true that Moses could not pass the examination given by the Bar Association nor could Noah qualify as commander of an ocean liner. These limitations, however, should not be held against either Noah or Moses; neither should one criticize the public of today for insisting that their legal advisers and their ship commanders should have knowledge commensurate with twentieth century requirements.—Ed.]

A NEW CONCEPTION OF THE CAUSE OF SCARLET FEVER AND THE OTHER ACUTE EXANTHEMS

To the Editor:—In 1895, Bergé ("La pathogénie de la scarlatine," Paris) said, in regard to the cause of scarlet fever, "An imposing array of evidence points to the streptococcus in one of its virulent forms as the pathogenic agent of the disease." Time and further experimental work have served only to strengthen this belief in the minds of many investigators.

It is generally assumed that the chief portal of entry for the causative agent in scarlet fever is the upper respiratory tract, more particularly the throat and tonsils. However, the many apparently typical cases of scarlet fever developing shortly after childbirth, severe burns, wounds and surgical operations suggest the fact that the causative agent may also find extrafaucial portals of entry. For many years we have been aware of the relation between complicating streptococcus infection and childbirth, burns, wounds and surgical operations.

How is it possible for the same micro-organism to cause in some persons the typical symptoms of ordinary streptococcic puerperal septicemia, streptococcic wound infection and streptococcic sore throat, and in other persons a typical or atypical scarlet fever? What, after all, is the difference between a case of septic sore throat due to the streptococcus and a case of so-called scarlet fever? I would suggest that these various conditions are due to differences in the susceptibilities of persons to the streptococcus. Scarlet fever may possibly be described as a streptococcic anaphylaxis superimposed on a streptococcic sore throat, or on a septicemia from some other portal of entry, in a person who has previously been made sensitive or hypersusceptible to the streptococcus, either through the gastro-intestinal tract or in some other way.

This conception is based on a thorough study of both scarlet fever and anaphylaxis. I am sure that the more one studies these two conditions, the more convinced one will become that the former is nothing more than a special manifestation of the latter.

Furthermore, may we not explain the other acute exanthems on the same basis? The only differences may be in regard to the specific micro-organisms and the portals of entry concerned in sensitization and intoxication.

When the time comes in which the microscope seems to fail us in the further search for a specific causal agent, should we not attempt to correlate the various facts that we already have at our disposal, and make intelligent use of them for the explanation of certain diseases that may depend on something more than a mere primary infection with a micro-organism? Leverett Dale Bristol, M.D., Augusta, Maine.

State Commissioner of Health.

Military Medicine.—The fundamental object of the Army Medical Service in war is to provide healthy men for the fighting line, to keep these men in good physical condition, and if sick or wounded, to make them fit and ready for fighting as soon as possible.—Col. T. H. Goodwin.

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CHLOROFORM IN STERILIZATION OF CULTURES

To the Editor:—In The Journal, Nov. 10, 1917, p. 1658, appears an abstract of an article by G. Stradiotti and G. Ollino on "Autogenous Vaccines in Treatment of War Wounds," published in the *Rivista critica di clinica medica* (1917, **18**, 357) in which the statement is made that chloroform was used to sterilize the cultures. Can you give me information as to the amount of chloroform used to sterilize the vaccines?

W. E. Putz, M.D., Chicago.

Answer.—The technic is only casually mentioned, as follows: "For the sterilization of the cultures, the method selected was always the addition of chloroform in slight excess to the culture fluid, agitating at intervals during two or three hours; after this the fluid was always absolutely sterile; so much so that in the several hundred injections we made we never noted an abscess or febrile reaction of any account or evidences of local intolerance; we noted nothing but fleeting redness at the site of the injection, and the usual slight painfulness, which never lasted more than a few days."

Wyoming: Laramie, Feb. 6-8. Sec., Dr. H. E. McCallum, Laramie.

Washington July Examination

Dr. C. N. Suttner, secretary of the Washington State Board of Medical Examiners, reports the written examination held at Seattle, July 3-5, 1917. The examination covered 11 subjects and included 110 questions. An average of 60 per cent. in each subject was required to pass. Of the 43 candidates examined, 40, including 5 osteopaths, passed, and 3 failed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, Los Angeles	(1916)	93.6
	(1917)	81.7
Hahnemann Med. College of the Pacific ..(1916) 74.5;	(1917)	83.9

Book Notices

Report of the Physical Welfare of Mothers and Children: England and Wales. Volume 1. By E. W. Hope, M.D., D.Sc., Medical Officer of Health for the City and Port of Liverpool. Volume 2. By Janet M. Campbell, M.D., M.S., One of Senior Medical Officers, Board of Education. The Carnegie United Kingdom Trust. Paper, 1917.

"Save the babies that are born" is the central idea of this report. The object is avowedly to stimulate interest in the task of reducing the amount of illness and mortality among mothers and children of the poor. The authors consider such aspects of the problem as the incidence of infant mortality and its relation to poverty, municipal sanitation, the establishment of antenatal and postnatal centers, special aid for expectant mothers in rural districts, and the training of health officers and midwives.

It is pointed out that bad housing and poverty go hand in hand, and that the economic condition of the parent is largely responsible for congenital weakness in the child, since the struggle for existence among the poor reacts on the fetus. The importance of proper sanitation is recognized for the reason that filthy courts and alleys, bad drainage, and the absence of personal and domestic hygiene are powerful factors in the intestinal diseases of infancy. Diarrhea and enteritis are cited as common in neighborhoods in which defective sanitation and bad housing are prevalent.

Considerable attention is paid to antenatal and postnatal supervision of mothers and babies by the health authorities. The antenatal clinic reduces the number of stillbirths and miscarriages among the poor, and aids in training the prospective mother for the future care of her child. It also enables the practitioner to detect and check such ailments as varicose veins, albuminuria and ophthalmia, and in cases in which syphilis is suspected, to apply the Wassermann test with the aid of the local bacteriologic laboratory. Postnatal supervision in England and Wales includes provision for the registration of births and deaths by the authorities, and for the recording of a brief life history of the child, as well as for visits to the home at intervals until the child is of school age.

The provision of sanatoriums for expectant mothers in rural districts is not yet an accomplished fact in the United Kingdom, but the authors strongly recommend their establishment, on account of the difficulty of getting skilled medical aid to the mothers in periods of emergency. On this account, Wales and parts of England remote from London and the great towns suffer more than the latter in infant mortality and loss of maternal life. The authors also recommend the subsidizing of midwifery service in rural districts by the county councils.

The need of intelligent health authorities is emphasized because of their responsibility, not only in problems of municipal housing, but also in the exercise of authority over the practice of midwifery. The regulation and training of midwives receives the fullest attention from the authors. They report a decided decline in the death rate from puerperal septic diseases from 1900 to 1914, as a result of the passage of the Midwives Act in 1902, whereby the practice of midwifery by uncertified midwives was made practically impossible. Through the agency of the Central Midwives Board, which was established to regulate the training, examination, certification and conduct of the practice of midwives, the standard has been materially raised.

In the second volume of the report, much attention is devoted to a historical survey of English midwifery during the period from the sixteenth to the nineteenth century, inclusive. It also contains a valuable chapter on modern conditions in England and Wales, and another on present-day practice of midwifery in Austria, France, Germany, Russia and Switzerland. Attention is directed to the fact that whereas in the United States the general tendency is to eliminate the midwife because of the low grade of intelligence her type represents, the policy in European countries is to improve her status and educate her more broadly for her work. In England, as on the continent, she is recognized as a permanent institution, through whose care passes a large percentage of the births in the United Kingdom, amounting, in some urban centers, to more than 75 per cent.

The report includes many interesting charts showing the incidence of maternal and of infant mortality; tables of returns from medical health officers; model plans of health administration; model housing and playgrounds specifications, and abstracts of the Midwives Act, the Notification of Births Act and other legislative enactments affecting the welfare of mothers and children.

Notes on Galvanism and Faradism. By E. M. Magill, M.B., B.S., D.P.H. Cloth. Price, $1.50 net. Pp. 220, with 67 illustrations. New York: Paul B. Hoeber, 1916.

This is a concise statement of the facts concerning this much neglected branch of therapeutics. As stated by the author, the book is primarily intended for the use of masseuses; but the practitioner who does not have the time or desire to wade through the larger and more technical works can get a good working knowledge of the subject from this book. One of the especially pleasing features is the giving of exact and minute directions to the student for applying the different treatments.

Social Medicine, Medical Economics and Miscellany

An Irruption of Antiseptics

Under this heading, the point of view of the pharmacist is thus presented in an editorial note in the *Pharmaceutical Journal and Pharmacist* (1917, **99**, 120):

"While the pharmacist is not professionally concerned with the relative therapeutic merits of the many antiseptics which have had a vogue in the past or are now competing for supremacy, he is bound, both for professional and business reasons, to keep himself conversant with all the latest phases of antiseptic treatment, with special reference to new antiseptic compounds and preparations. Sooth to say, since the outbreak of war this has been no easy task. One result of the enormous demand for hitherto staple and standard antiseptics for the treatment of war wounds has naturally been to stimulate research for the discovery of effective substitutes, while the progressive surgeon, always on the *qui vive* for improved methods of asepsis or antiseptics, has utilized to the utmost the legitimate opportunities afforded by unprecedentedly vast and varied clinical experience to give a trial to antiseptic agents and methods for which in normal times there would have been little or no opening. It is hardly an exaggeration to say that for a year or more the medical journals have announced new antiseptics at the rate of about one a week, and the battle between the partisans of the different discoveries rages loud and long. Fortunately it is not our affair to adjudicate on the issues of the controversy, but the unfortunate pharmacist can hardly be an indifferent spectator of it, seeing that he may be expected to stock or prepare on short notice one or other of the variants of, say, Dakin's solution or the paraffin compound for the treatment of burns, or to reel off for the information of the medical inquirer all about the chemistry and transcendent potency of chloramin-T, or any of the other chemicosesquipedalianly named compounds which we are assured is destined for ever to supersede all its predecesors and contemporaries. It would ill become us to belittle any effort toward the advance of antiseptic surgery, or to deprecate the need for continuous criticism and revision of existing methods and material. We have traveled far since Lister revolutionized clinical surgery as regards the prevention and treatment of the microbic infection of living tissues. But the principles on which his method was based, while not unchallenged, remain unshaken. Such differences as do obtain refer exclusively to methods of treatment or to the superiority of one antiseptic over another. In the meantime, happily, the patient is not sacrificed to an absolutely bad as compared with a perfectly good method. At the worst, all that happens is that the inferior method may delay the cure. From the pharmacist's point of view, it would be an immense relief if it were possible for the medical profession, if not to adopt Sir Almroth Wright's simple saline plan, at least to attain to some measure of standardization and uniformity in the selection and use of antiseptics, so as to minimize the practical difficulties and vexations inherent in the present lack of system, which opens the way for the needless multiplication not only of antiseptics, but of variants in the composition and preparation of them for use."

Medicolegal

Liability of Employer for Surgical and Hospital Services After Thirty-Day Period

(In re Henderson (Ind.), 116 N. E. R. 315)

The Appellate Court of Indiana, answering an inquiry of the industrial board of the state, says, in construing Section 25 of the workmen's compensation act, that it will be seen that such section provides for the furnishing by the employer of an attending physician in two instances only, namely, during the thirty-day period from the date of the injury, when he is required to furnish such physician, and thereafter when he may at his option furnish such physician. The additional services of a surgeon and hospital are limited to said periods and conditions. There is no authority to furnish the latter services except during the period of the attendance of the physician, furnished as indicated. If during the first thirty days after the injury the employer furnishes such physician, or, without cause, fails to furnish such physician, in either event the attending physician or the industrial board may during such period require surgical and hospital services for which the employer may be properly charged. However, after the thirty-day period no obligation rests on the employer to furnish an attending physician, and in the court's judgment the board has no authority or discretionary power by which it may require such a service after the expiration of said period; and hence, unless the employer elects to furnish such attending physician, the power of the board to require surgical and hospital services and supplies ends with the expiration of the thirty-day period. But the legislature intended that, so long as the employer continues to exercise the option that the statute gives him, to furnish voluntarily the injured employee a physician, if either such physician or the industrial board should determine that any surgical or hospital services are necessary in such case, the employer should be liable therefor. Moreover, if in this case the industrial board is of the opinion that the evidence before it shows that the emergency for the amputation of the employee's foot arose before the expiration of the thirty-day period, and that such amputation should have been and could have been performed before the expiration thereof, and that the employer was responsible for the delay that prevented the amputation before the expiration of such period, the board would be authorized, under the section of the act in question, in holding such employer liable for any surgical or hospital service and supplies that were in fact furnished or might have been furnished within said period, notwithstanding the employer's written notice to the attending physician and the hospital that he would not be liable for any surgical and hospital services after the expiration of thirty days from the date of the injury, and notwithstanding such services may not have been in fact furnished until after the expiration of said period.

Proof Required of Standard of Care and Skill

(Norkett vs. Martin (Colo.), 165 Pac. R. 256)

The Supreme Court of Colorado, in affirming a judgment in favor of the defendant, a physician, says that this action was brought by a minor suing by her next friend to recover damages for alleged negligence in the diagnosis and treatment of an ailment from which she was suffering, a verdict being returned for the defendant and a judgment of dismissal being entered thereon. The only error alleged was in an instruction to the jury which read: "In considering whether the defendant, in his diagnosis, care and treatment of the plaintiff's injury or disease exercised ordinary care, you cannot set up a standard of your own, but must be guided in that regard solely by the testimony of the physicians, and if you are unable to determine from the testimony or the physicians what constituted ordinary care and skill under the circumstances of this case, there would be a failure of proof on the only standard for your guidance, and the evidence would be insufficient to warrant any verdict for the plaintiff." Counsel conceded that this instruction was a copy of one that was approved in *McGraw* v. *Kerr,* 23 Colo. App. 163, 128 Pac. 870, but insisted that a difference in facts rendered that case inapplicable. But this court cannot agree with that conclusion. The court there was considering, and discussed at some length, by what evidence a jury should be guided in determining whether or not a physician had exercised such care and skill as his employment required, and held that it was a question for experts. It also held that "if no standard was established by the testimony of physicians, then the jury had no standard." This case is clearly within the rule thus laid down. The principle on which the rule is based was announced by the court in *Jackson* v. *Burnham,* 20 Colo. at page 536, 39 Pac. 577, and is supported by abundant authority. The instruction was correct.

Treatment of Cancer of Mouth by Dentist Under Direction of Physician

(In re Carpenter's Estate (Mich.), 162 N. W. R. 963)

The Supreme Court of Michigan affirms a judgment in favor of the claimant, a dentist, who charged for treating and cleansing cancer of the mouth three times a day for seventy-seven days, at $2 per day, and from four to six times a day for sixty-four days, at $3 per day; and made three charges of $4 each for cocain and antiseptic. The court says it appeared from the record that the patient was suffering from an incurable cancer of the mouth. The record also showed beyond question that the treatments administered by the claimant were so administered from the very first under the direction of a duly qualified physician, first under one physician, and later under another. It further showed that such treatments were necessarily administered from three to six times each day, the lesion in the jaw being extremely painful, and emitting a discharge highly offensive in odor. It further appeared that in the administering of said treatments some skill was required. No question was raised in this record as to the value of the claimant's services. At the conclusion of the claimant's case, counsel for the estate made a motion for a directed verdict on the ground that the services rendered by the claimant were for the treatment of a cancer by a man not shown to be legally qualified to practice medicine in the state of Michigan; that a treatment of cancer by a dentist is a treatment in violation of the law. He said: "The only question of importance involved in this case is whether the claimant in doing what he did for the decedent was engaged in the practice of medicine contrary to the provisions of Act 237 of the Public Acts of 1899 as amended." But the court is of the opinion that the claimant was entitled to recover on either of two theories: First, that the services rendered were those of an ordinary nurse under the direction of a competent and duly qualified surgeon; and, second, that they were rendered by the claimant as a duly qualified dentist under the provisions of Act 183 of the Public Acts of 1913, Section 7 of which provides: "Any person shall be said to be practicing dentistry within the meaning of this act . . . who shall . . . treat diseases or lesions of the human teeth or jaws, . . . or who shall for a fee, salary, or other award paid or to be paid, . . . treat diseases or lesions of the human teeth or jaws." The treatments administered by the claimant would clearly fall within the definition of the practice of dentistry contained in the statute. The court is of the opinion that the claimant in rendering the services for which claim was made was not practicing medicine within the meaning of Act 237, Public Acts of 1899, nor of Act No. 368, Public Acts of 1913.

(Continued from page 2067)

Tetanus Following Laparotomy for Ectopic Pregnancy; Treatment by Subarachnoid Injections of Magnesium Sulphate and Antitetanic Serum; Recovery

Dr. Dewitt B. Casler, Baltimore: Certain patients are definite tetanus carriers, and, as such, are liable to be a source of infection to themselves in any surgical operation on the bowel, or about the rectum. In any abdominal operation, especially in pelvic work, when the surgeon has to deal with inflammatory masses, indurated and adherent to the bowel wall, great care should be taken to close in this indurated area as thoroughly as possible, and so avoid the danger of tetanus developing in the injured bowel wall. In every case of postoperative tetanus, it is wise to begin at once subcutaneous injections of magnesium sulphate, and in the severe cases, subarachnoid injections. There is always a certain amount of danger from paralysis of the respiratory center, and when subarachnoid injections are given, means for artificial respiration should be at hand. Magnesium sulphate given intraspinally affords the greatest amount of comfort and relief in those cases, in which death often comes, not only from the toxemia, but also from exhaustion.

Popularizing Public Health

Drs. C. E. Terry and F. Schneider, Jr., New York: As a means of bringing to the public a realization of health truths and a knowledge of the importance of health work, the family magazine has unparalleled possibilities. The seventh baby campaign has pushed this experiment in constructive journalism a step farther. A field force of trained and experienced public health nurses has been assembled, and two traveling laboratories with experienced laboratory men have been provided. This field force is now engaged in making surveys of infant mortality in particular, and public health work in general, in communities of between 10,000 and 40,000 population. Careful inventories of local conditions are made, and reports are submitted giving findings and outlining a practical program for public health progress. The field work is conducted only on the request of local authorities, and with their cooperation. The subjects covered are infant mortality in particular, that is, the number and causes of infant deaths and existing efforts to prevent them; milk supply; water supply; sewers and sewage disposal; privies and fly-breeding; waste disposal, and organization and budget of the health department.

Distribution of Vaccines and Serums by the State

Dr. C. A. Shore, Raleigh, N. C.: Cities and many counties should have their own laboratory for diagnostic purposes and for the control of water and milk supplies. The state laboratory should serve sections not otherwise provided for, and in addition should have a much wider field of usefulness and a direct public health service in making and distributing those vaccines and serums that have been accepted as reliable curative or prophylactic agents. In our state, typhoid vaccine is given free to all registered physicians. We have been sending out annually for three years an average of 400,000 doses. We estimate that at least 100,000 citizens are immunized against typhoid fever each year. I believe in the free distribution of diphtheria antitoxin. It is only then that we can hope for its use in all cases of diphtheria.

Health Education in Rural Districts

Dr. L. A. Riser, Columbia, S. C.: Two counties in South Carolina were this year induced to appropriate money through the legislature for a campaign for better health in their rural districts. Notwithstanding the phenomenal rise in the price and scarcity of labor and material in our state, we have been able to make a fair showing, and to stir up an enthusiasm for civic betterment along the line of disease prevention that will cause a demand on the part of the rural population in these counties for a continuation of this work next year. We have largely stressed the prevention of intestinal diseases by approved methods of sanitation, but we have also devoted a part of our work to the prevention of tuberculosis, and diseases of childhood. Lectures in schools, both negro and white, have been given in practically every community. In our county and community fairs we have had health exhibits, which have taught valuable lessons in disease prevention to thousands.

Relative Value of the Public Health Nurse in the Solution of the Tuberculosis Problem

Dr. W. L. Heizer, Frankfort, Ky.: The chief advantages of starting a health campaign in a county by employing competent public health nurses are: the natural inclination of a community to spend a smaller amount of money, a false economy, to accomplish a public service; the popular appeal to the public by the ministrations to the sick; the prenatal care in selected cases, and a quick appreciation of the value of public health work by reason of its publicity, secured as the result of appeals for aid to churches, fraternal organizations, and the city and county government. When a nurse is employed by a county health and welfare league, as is the policy of our commission, or a similar organization with a large county membership, it is a logical and certain means of crystallizing an awakened public health sentiment to the formation of a permanent county, city or state health department with efficient officers and sufficient equipment and assistance to make real work permanent, constructive and effective.

Physical Status of Juvenile Delinquents

Drs. Elizabeth Bass and Maud Loeber, New Orleans: Many children who are sent to reformatories would make better men and women if even superficial attention were given to them before their commitment by a physician attached to the juvenile court, to be followed up in each instance, according to the opinion of the court, either by the child's natural or rightful guardian, or, should the court deem commitment proper, by the custodian of the municipal or state institution. Physical and clinical records should be kept of each child at the time of admission into the reformatory, and observations recorded once each month thereafter, or more frequently, should the case require it. Each reformatory attending physician should have as his assistants specialists in the various branches of medicine to treat cases needing attention in his specialty, and a resident trained nurse. The diet and mode of life in an institution should be passed on by that institution's attending physician.

DISCUSSION

Dr. Oscar Dowling, Shreveport, La.: The prison system in vogue is an insult to our intelligence and a disgrace to our civilization, and there is no feature of the whole system more in need of reform than that which pertains to the juvenile criminal. Although not complete, there are sufficient data to show the close and intimate relation of mental states to abnormal physical conditions. That defects or bodily pain are the cause of actions often mistakenly called criminal is clear. Then, logically, the cause should be discovered and the remedy applied. Every court should take cognizance of pain or mental defect as a predisposing cause of crime. No jury would convict an insane person. Institutional life at its best is not an environment which gives ideal results, and for the physically defective cannot be other than trying in the extreme. I heartily approve the recommendations contained in the paper, each one of which is important and imperative. I believe they are practical and can be put into immediate effect wherever public opinion will make the demand. I believe full publicity as to the details of juvenile court proceedings and institutional life will stimulate public sentiment to the degree that the demand will be made.

Syphilis of the Heart and Aorta

Dr. Bryce W. Fontaine, Memphis, Tenn.: The records of the Memphis General Hospital for the years 1916 and 1917, inclusive, show a total admission of 219 patients with cardiovascular disease. Disease of the cardiac valves heads the list with the occurrence of mitral insufficiency in 133 of the cases, and aortic insufficiency in twenty-four. Next in point of number were aneurysms of the aorta and the peripheral arteries, of which there were eighteen. Such a study showed in the cases of mitral disease thirty-seven, or 27.8 per cent., infected with syphilis; in the cases of aortic disease, eleven, or 45.8 per cent.; and in the cases of aneurysm, eleven, or 61.1 per cent. In every case of aortic insufficiency in a young adult, in addition to the physical and other examinations, there should be made a roentgenographic examination of the chest, for this may be the only means of differentiation from chronic aortitis or aneurysm.

(To be continued)

KENTUCKY STATE MEDICAL ASSOCIATION

Sixty-Seventh Annual Meeting, held at Louisville, Nov. 6-9, 1917

(Concluded from page 2067)

Acute Intestinal Obstruction

Dr. George A. Hendon, Louisville: Any acute illness that is characterized by abdominal pain, shock and nausea, not associated with diarrhea, is sufficient evidence of intestinal obstruction to justify laparotomy. An estimate of the degree of pain is important. Any abdominal pain that cannot be quieted by a hypodermic administration of one-fourth grain of morphin in the adult and corresponding doses in children is always indicative of an organic lesion. To this rule I have never found a single exception. Such a case will sooner or later demand surgical intervention. Nausea that persists after normal stomach contents have been evacuated is never due to local conditions in the stomach. Such nausea is due either to pyloric spasms or reversed peristalsis. To produce either pyloric spasms or reversal of the peristaltic wave, an obstruction, either physiologic or mechanical, must exist. If associated with pain, such as mentioned above, the obstruction is always mechanical. The nausea of intestinal obstruction is characterized more by its persistence than by its severity. Sometimes the efforts of vomiting are mild and devoid of violent retching, but they are constant and uncontrollable. The vomited material consists first of undigested food, then mucus and bile, and later of intestinal contents. It is utterly inexcusable to wait for fecal vomit before making a diagnosis. Shock is a conspicuous symptom and is always present. The greater the degree of vascular involvement in the obstruction, the more profound is the shock.

DISCUSSION

Dr. J. Garland Sherrill, Louisville: Patients with intestinal obstruction die not so often of peritonitis due to the original trouble as from the absorption of the contents of the bowel. If we give such a patient purgatives, he will certainly die.

Dr. A. D. Willmoth, Louisville: The conditions presented by Dr. Hendon are not due to infection but to the absorption of material within the intestine itself. The mucosa of the intestinal tract is not only a simple absorbing and secreting surface, but under certain conditions it has the power of manufacturing chemical agents that may destroy the patient's life rapidly unless some form of drainage is instituted.

Dr. D. W. Payne, Bardwell: In the last year I have had three cases of acute intestinal obstruction in which the symptoms of abdominal pain, nausea and diarrhea were conspicuous by their absence.

Latency in Tuberculosis

Dr. Josephus Martin, Cynthiana: There is often a period of latency in tuberculosis. Just in what percentage of cases and exactly how this comes about is not well established. Deaths from consumption are infrequent before the fifteenth year. The careful study of tuberculosis would indicate an attempt on the part of nature at the production of acquired immunity in this disease. This is the case in as high as 95 per cent. of children examined. Latent tuberculosis in children is often revealed by defects in development. The previously normal appearing child begins to grow thin and pale; the skin and muscles feel flabby, and the bones are inclined to soften and bend. The mind often develops precociously. Children with latent tuberculosis catch cold readily; eczema and pruritis are frequent, and there may be periods of difficulty in breathing, with or without bronchitis. Pains at different points are also instructive.

Surgical Management of Hypertrophy of the Prostate

Dr. H. H. Grant, Louisville: Early removal of the prostate in the first stage, with tumor and residual urine, is a wise step. In the second stage, when the urine has become foul, the prostate should be removed by the two-stage method as soon as the patient is in condition to bear surgery. In the first stage, when surgery is unsafe, suprapubic drainage will often make the patient comfortable. The shock of the perineal operation is far less and the subsequent convalescence much more rapid and comfortable than in the suprapubic method, but it should be reserved for the small prostate about the neck of the bladder and for those grave cases in which something must be done, in which the more trying operation is too dangerous. These patients are not to be allowed to drag along with a few antiseptics for the urine and various temporizing methods until the opportunity for security in surgery has passed.

DISCUSSION

Dr. Herbert Bronner, Louisville: A class of cases the essayist did not mention is that class with nerve lesions. We not infrequently see patients who have hypertrophy of the prostate, but in whom the prostate is not palpable by rectum. Large sounds can be passed with ease. The cystoscope will reveal a trabeculation that is characteristic of nerve lesions.

Dr. Frank Boyd, Paducah: I wish to call attention to the danger of too rapid evacuation of a bladder that has long been under tension from overdistention. The better plan is to withdraw 10 ounces of urine at a time, gradually emptying the bladder in two or three days. In that way we overcome the tendency to rapid dilatation of the bladder wall.

Early Diagnosis and Treatment of Ectopic Gestation

Dr. Charles A. Vance, Lexington: Prompt operative intervention is imperatively demanded in every instance, regardless of the stage of the gestation when the patient comes under observation. In the presence of severe abdominal pain and shock, even when the diagnosis is uncertain, celiotomy is justifiable and may be a life-saving measure. Vaginal operations are not advised under any circumstances in the treatment of ectopic gestation. The primary object to be borne in mind is the safety of the mother. It is inadvisable to delay operation, hoping that the product of conception may be finally extruded through the tubal fimbriae without hemorrhage or shock, since it is impossible to determine in what portion of the tube impregnation has occurred.

Border Line Tonsils

Dr. W. B. McClure, Lexington: No matter how much the tonsil may be hypertrophied, or how much it apparently is diseased, unless there is a history of tonsillitis or quinsy, unless there are glandular enlargements about the neck or throat, unless there are constitutional symptoms of tonsillar origin, I unqualifiedly advise against their removal.

Celiohysterectomy for Puerperal Eclampsia and Placenta Praevia

Dr. Woodson H. Taulbee, Maysville: I do not propose cesarean section in every case of eclampsia or in every case of placenta praevia, but there are definite indications which make this procedure not only justifiable but the safest to both mother and child. When immediate delivery is indicated, cesarean section is often the method of choice. Every patient with eclampsia and placenta praevia or concealed hemorrhage should be given the promptest treatment possible after the first convulsion or hemorrhage. Celiohysterectomy is done rapidly; shock is greatly lessened; the control of hemorrhage is more complete; there are no cervical tears; there is less likelihood of infection; we are not working in the dark; delivery of the placenta is immediate; there is less likelihood of postpartum hemorrhage, and less danger of injury to the bladder; a living child is more certain and, if deemed necessary, the patient may be sterilized.

Treatment of Cardiac Disease by Measures Other than Drugs

Dr. Curran Pope, Louisville: Rest is an essential feature of every method and every system of treatment of cardiac diseases. Physical rest may be obtained in many ways. In some cases rest may be obtained by simply diminishing the day's work and increasing the time of general physical rest. This form of rest is particularly valuable in ambulant cases with slight or moderate weakness of the myocardia. Psychic rest is almost as important as physical rest. As far as possible, the so-called "worries" should be removed. The vast majority of such worries are in reality irritations that can be removed readily by hospital residence. The management of the diet of these patients commences with cleanliness of the entire oral cavity. Mastication is essential, and this is best secured by having the patient take small mouthfuls of food, chewing it well. We diet our cardiac patients too much. One of the most valuable, as well as the simplest, hydrotherapeutic measures in the treatment of cardiac diseases is the precordial ice bag. The ordinary ice bag or cap may be used, and should be filled with small pieces of ice to which some ordinary coarse or rock salt has been added, in the proportion of one of salt to four of ice. Massage is a very practical and useful adjunct in the treatment of cardiac diseases and disorders. In bedridden cases, manual massage and vibration have been used successfully. The sinusoidal current is of considerable value in the treatment of cardiac diseases and disorders. It seems to be especially useful in myocardial disturbances. I employ an even, smooth, short wave without surging of any kind. It produces the most lasting impression.

NEW YORK NEUROLOGICAL SOCIETY

Regular Meeting, held Oct. 2, 1917

The President, Dr. Frederick Tilney, in the Chair

Cinematographic Records of War Neuroses

Dr. Frankwood E. Williams, Associate Medical Director of the National Committee for Mental Hygiene: Shortly after the declaration of war, the Surgeon-General created in his department a division of psychiatry to organize a neuropsychiatric service in the Army to meet the problem of war neuroses as it developed in the American forces. Dr. Pearce Bailey, chairman of the Mental Hygiene War Work Committee of the National Committee for Mental Hygiene, was given charge of the new division. The creation of this division of psychiatry represented the first attempt in any army to take into consideration the mental and nervous qualifications of recruits for military service.

The National Committee for Mental Hygiene then undertook to interest the neurologists and psychiatrists throughout the country in this work. The result was that whereas there were few medical officers in the Army at the time of the declaration of war who could be called psychiatrists or neurologists, there are now approximately 300 of these specialists commissioned in the Medical Reserve Corps. There have been, of course, many new problems before the division, but the work has divided itself largely into three parts: (1) the examination of recruits, (2) provision for the care of war neuroses in the expeditionary force, and (3) provision for the care of invalided soldiers returned to this country. Psychiatrists and neurologists are now detailed to each of the American camps, where they are examining the troops in a systematic way in order that those recruits will be eliminated who are found unfit for military service because of neuropathic or psychopathic conditions. No statistics are available at the present time, but it is estimated that from 1 to 2 per cent. are being eliminated.

In order that the cooperation of line officers might be obtained, a special report was prepared indicating those personality traits that frequently come to the attention of such officers and which are considered of possible psychiatric significance, and they are requested to refer those men to the specialists for examination.

Neuropsychopathic wards are being planned for the base hospitals at each of the sixteen cantonment camps. Three or more psychiatrists and a corps of specially trained attendants are to be detailed to each of these hospitals, which will be provided with adequate hydrotherapeutic and electrotherapeutic equipment. The plans for the expeditionary force called for thirty bed neuropsychiatric units with each base hospital and for a 500 bed special hospital for war neuroses. The latter will be staffed by nineteen medical officers, a corps of 150 nurses and male attendants, and a corps of specially trained reeducational workers. It is probable that eventually specialists from the base hospitals will be on duty at the casualty clearing stations so that a patient can be handled from these stations through the base hospital unit and, if necessary, through the special hospital for war neuroses.

War Shock, Its Occurrence and Symptoms

Dr. T. H. Ames: From observation of chronic cases of war neuroses in convalescent hospitals in different parts of eastern Canada, I believe that a classification for the differential diagnosis of every case of nervousness developing at the front might be made in the following way: (1) Constitutional inferiority group, including the high grade morons and epileptics. (2) Psychoses, such as general paresis, dementia precox and manic depressive states. (3) Concussion, that is, organic injury to the brain or spinal cord, so that on physical examination disturbances in reflexes and in the spinal fluid were demonstrable. (4) War shock, or the functional cases which had no organic signs, either wounds from bullets or shrapnel, and showed no abnormal changes in reflexes. (5) Malingering, or deliberately feigned symptoms.

A rough estimate of cases of nervousness in all forms is about 3 per cent. of all the casualties, perhaps one half being cases of war shock.

It is interesting to study the types of men who suffered from these conditions. Throughout the war it had been a matter of continuous comment that prisoners of war and wounded men did not have war shock. All nervousness ceases instantly on being wounded, and war shock never develops in a sleeping man when a shell bursts near him. Crack regiments have fewer men coming down with war shock, as do old regiments with long traditions of pride. Among officers there is relatively a smaller percentage than among privates. One of the most striking features is the relatively small number of cases among woman nurses and civilians who are often exposed to shell fire.

The immediate exciting incident provoking the attack might be either a physical or an emotional shock. Being gassed, aeroplane raids, mine explosions, or anticipated mine explosions act as exciting causes. The emotional causes are apt to produce less sudden onset of symptoms; the factors are most frequently fear or suspense. The large percentage of cases, however, have their onset some time after the shock, some of the men coming out of unconsciousness and being for several days without any symptoms at all, then developing mutism, blindness, tremors, etc. Once the symptoms appear, they are apt to assume their maximum severity within twenty-four hours. As a rule, from the time the man was taken care of the symptoms began to abate, subsiding, in the majority of cases, one by one, at irregular intervals. Some of the symptoms that disappeared did so in a few moments' time; the use of the voice came back all at once, blindness disappeared almost instantaneously, as did paralysis, though the use of limbs that had been paralyzed might be slow and gradual. The cessation of tremors, however, had never been rapid. The course of the disease might be continuous or interrupted, exacerbations being quite common. The severity of the symptoms varied in many respects. Some were extremely severe and others very mild. Those cases which were monosymptomatic were apt to be more severe than those with more than one symptom. The intensity of any symptom was in inverse proportion to its duration. The symptoms might be classified as psychical or physical. There was a third group involving the autonomic system, gastro-intestinal, cardiac, respiratory, secretory or excretory systems.

DISCUSSION

Dr. John T. MacCurdy: The prevalence of "shell shock" is not well known because no statistics have been published. Major Bailey showed that 12 per cent. of those invalided home to Canada suffered from neuroses and mental diseases, 58 per cent. of which had a diagnosis of "shell shock." The War Council of Great Britain gave Major Salmon statistics of all discharges from the British Army; one seventh of these were for mental and nervous troubles, of which the largest proportion were war neuroses.

War neuroses seem to be constant and simple in their type. In England, I visited seven or eight special hospitals for nervous cases and found that the physicians who did most for their patients and returned the most men to active duty classified their material into two groups, anxiety neuroses and the conversion hysterias. In the anxiety neuroses the symptoms were almost purely psychic, in contrast to the hysterias, where the symptoms were somatic. A further difference was found in that the anxiety cases occurred mostly among officers. In Scotland, in a 300 bed hospital for officers, they had only one example of anxiety neurosis with gait disturbance; the other 299 were cases with no somatic symptoms beyond occasional tremors of brief duration. The paraplegias, the blindness, the mutism, tics, etc., constituted the hysterias, and these occurred preponderantly among the private soldiers. Privates, as a rule, were comparatively ignorant men; they were not surprised to find a scratch on the shoulder resulting in paralysis of the arm, a sequence which an educated man would view with astonishment. This was one reason for the rarity of hysterias among officers, and corresponded to the experience in civilian practice, where functional palsies, etc., were rarely met with outside of dispensary practice. The onset of the anxiety condition was gradual and usually marked by fatigue. The hysterias, on the other hand, developed quickly. It was the anxiety neuroses that had the greater military significance. The officer who later developed an anxiety state passed through a latent period during which he felt more and more fear and struggled against it. It was impossible for a man putting forth 90 per cent. of his energy in smothering fear to encourage his men with the necessary abandon; consequently their neuroses led to the breaking up of the morale of their companies.

The treatment for the two groups is different. Hysterical symptoms are amenable to suggestion, hypnotism and reeducation, all of which efforts are successful with anxiety neuroses only to a limited degree.

The common soldier hoped to receive some wound, a "blighty" one, and when his neurosis appeared the symptoms assumed corresponding physical form; his sight went or the tics, paraplegias, etc., developed. The officer had higher ideals; he would not harbor the thought of being disabled; he did not want to get out of the war by any subterfuge, and so it came about that he developed a fear of death and fearful dreams of being killed began. When this occurred his sleep was disturbed by nightmares, and this aggravated his condition until it was only a question of time before he broke down. All these premonitory symptoms went on for some time and just how fast they developed to the point of incapacitation depended on circumstances. The soldier was waiting for some final precipitating factor which might be a purely psychic trauma or a physical accident such as concussion.

Dr. Charles L. Dana: The disorders and symptoms described under the term "war shock" are not new. The grouping of the cases and classification corresponds to the groups of neuroses and psychoneuroses seen in civil life as the result of trauma and shock. The frequency, however, of different types and the combination of symptoms are different in war shock and civil shock cases. Thus, in civil life there are very few cases of hysterical mutism, deafness, or blindness, but plenty of tremor, paralysis and skin anesthesia. The group which the term neurasthenia covers better than "anxiety neuroses" seems to have much the same characters as the traumatic neurasthenias of civil life, where there are often types of mild depressions brought out by shock; neither war nor civilian shocks are often the real cause of the obsessive psychosis. The main measures to pursue in trying to prevent or to prepare individuals against shock are the avoidance of excessive fatigue and education against fear, measures which are rather councils of perfection. The ear and the body can, however, be educated to withstand the noise and concussion of cannon firing and shell explosion, as has been shown in the artillery branch of the army service, where soldiers, ignoring ear protectors, sleep peacefully in the gun pits of even the heavy artillery.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

5 Seasonal Changes in Interstitial Cells of Testis in Woodchuck (Marmota Monax). A. T. Rasmussen, Ithaca, N. Y.—p. 475.

4. **Shape of Mammalian Red Blood Corpuscles.**—Arey is convinced that the shape of the mammalian red blood corpuscle depends largely on the osmotic pressure of the examining medium. In solutions corresponding to calcium 0.9 per cent. sodium chlorid the erythroplastid possesses a biconcave form. In progressively less concentrated (hypotonic) solutions water is imbibed and the corpuscles swell to thin-walled cups, thick-walled cups, dimpled spheres and finally lake forming shadows. In hypertonic media crenation results. Between the limits of form induced by a 0.3 per cent. sodium chlorid solution and by mild crenation the shape of the red corpuscles is repeatedly reversible. Individual variability exists in the response of erythroplastids to diluting media; this is perhaps referable to diverse elasticities of the corpuscular membranes. Undiluted drawn blood, and blood diluted with human serum, show the red corpuscles to be biconcave disks. Human serum must be diluted about one third with water before the cup form predominates. Freezing point determinations which show that mammalian plasma is isotonic with a 0.9 per cent. saline solution (instead of 0.6 per cent.) are roughly substantiated by such dilution experiments. The study of circulating blood in nonanesthetized living mammals corroborates the normality of the disk. The results gained by the use of fixatives, although seemingly adverse to the disk view, may be satisfactorily interpreted in terms of unequal fixation; this is supported by experiment. The several lines of evidence presented by Arey seem to justify the conclusion that the biconcave disk represents the normal shape of the mammalian erythroplastid—the concavoconvex cup being merely an occasional modification.

15 Formula for Rate or Nerve Conduction in Sea Water. A. G. Mayer, Washington, D. C.—p. 591.

6. **Occurrence of Citric Acid in Urine.**—With the intention of studying the fate of citric acid introduced in the organism by various routes and in various diseases, Amberg and McClure tested the applicability of the method of Kunz to the quantitative determination of citric acid in the urine and other body fluids. They found that citric acid is a normal constituent of the urine of infants, children and adults. Quite an appreciable amount of citric acid is excreted in the course of twenty-four hours, enough to play a modest rôle in the acid base economy of the organism. The amount excreted varied from 21 to 50 mg. per 100 c.c.

9. **Experimental Thyroid Hyperplasia.**—Adult rats kept under hygienic conditions and fed a high protein diet were found to develop hyperplasia of the thyroid gland. Rats kept under unhygienic conditions develop hyperplasia of the thyroid if given a standard diet of bread and milk. Unhygienic conditions plus a high protein diet bring about a higher degree of hyperplasia in the adult rat than either factor taken alone. Young, growing rats kept under hygienic conditions do not develop hyperplasia of the thyroid when given a high protein diet which will induce this condition in adult rats. Feces either from goiter patients or from goitrous dogs fail to induce any changes in the thyroid of the cat when given by stomach. The central end of the phrenic nerve when sutured to the peripheral end of the cervical sympathetic either does not form a physiologic anastomosis or, if formed, the stimuli thus carried are not efficient in increasing the output of thyroid secretion to the point of producing the pathologic changes accompanying exophthalmic goiter in man. Removal of a section of the cervical sympathetic cord produces no change in the thyroid gland in the cat, indicating that secretory fibers, if there are such fibers present, play no part in the normal mechanism of thyroid secretion.

12. **Epinephrin Secretion and Experimental Hyperglycemia.**—The relation of the epinephrin secretion of the suprarenals to experimental hyperglycemias can be investigated under much better conditions in animals whose epinephrin output has been abolished or greatly reduced by removal of one suprarenal and section of the nerves of the other, than in animals deprived of both suprarenals. For in the first case the animals, after recovery from the operation, remain indefinitely in good health, whereas after total suprarenalectomy observations on the blood sugar are complicated by the fact that they must be made: (*a*) practically on dying animals (unless survivors in species where accessory suprarenals are common are employed) and (*b*) on animals suffering from the immediate effects of a major operation and anesthetization. The hyperglycemia associated with asphyxia and ether anesthesia is obtained in cats which have undergone the suprarenal operation described, even when no detectable residual liberation of epinephrin is present. No essential difference could be made out by Stewart and Rogoff in this regard between these animals and control normal cats. Accordingly, the mobilization of sugar, of which these experimental hyperglycemias are the expression, is not mediated through the epinephrin secretion of the suprarenals. Such observations as the authors have made on the effect of fright do not support the view that so-called emotional hyperglycemia is a constant or even a common phenomenon in cats. If it exists, it does not depend on an increase in the epinephrin liberated from the suprarenals. For (*a*) no essential difference could be detected between the results of emotional disturbance on the blood sugar content in the cats whose epinephrin output had been interfered with, and in the control normal cats; (*b*) no evidence was obtained that emotional disturbance increases the output of epinephrin in normal cats.

13. **Cause of Death from High Temperature.**—Mayer's researches lead him to believe that death from high temperature may be due to the accumulation of acid (possibly H_2CO_3) in the tissues, the rate of formation of this acid being commensurate with the rate of metabolism of the tissues. Thus animals of the same class having a high rate of metabolism, as measured by oxygen consumption, are more sensitive to heat and to carbon dioxid than are those having a low rate of metabolism. Death at high temperature is not due to asphyxiation.

14. **Oat Diet and Phenol Excretion in Guinea-Pigs.**—In guinea-pigs on an oat diet no changes in the urinary elimination of phenols nor in the degree of conjugation of the phenols were observed, provided the factor of partial starvation was ruled out. This is believed to indicate that no increased bacterial action occurs in the intestine of scorbutic guinea-pigs despite the difficulty of evacuation of the feces.

29 *Wassermann and Luetin Reactions in Tuberculosis. H. J. Corper, W. A. Gekler and H. C. Sweany, Chicago.—p. 544.
30 Relation of Fistula in Ano to Tubercle Infection. H. B. Stone, Baltimore.—p. 548.

26. **Present Status of Induced Pneumothorax.**—As the result of personal experience and a review of the literature Beggs would make the following summary: While the operation of induced pneumothorax per se is not a dangerous one, the practice of collapse therapy calls for special skill and judgment. Collapse therapy unquestionably restores to practical health many otherwise hopeless cases, and prolongs the lives and increases the comfort of many others. It is of positive influence in decreasing the period of incapacity. It should be used in all cases of recurrent, severe and protracted hemorrhage. It should be invoked, generally speaking, much earlier than is now the usual custom. In justice to the patient it should be considered in every case of advanced or moderately advanced, slowly progressive pulmonary tuberculosis, and in every case of actively progressive pulmonary tuberculosis in any stage, because the natural trend of all these is toward death. The constant tendency to diminution of the gas pocket by pleural contraction following exudation should be persistently combated by frequent refillings under positive pressure. Control by frequent roentgenographic and fluoroscopic examinations should be insisted on whenever at all possible.

27. **Artificial Pneumothorax in Treatment of Tuberculosis.**—In Minor's opinion the method is chiefly applicable to moderately advanced, or advanced chronic cases, with or

without acute exacerbations, but not to florid, acute cases, or to incipient ones, unless these show an acute waking up. It seems also that so far we have no definite guide as to the duration of the treatment, though after one year we should always consider the advisability of removing the gas and allowing the lung to reexpand. Minor is satisfied that many cases are kept collapsed too long. Further, it may at times be useful in cases of abscess of the lung, and in hemorrhage, if we can be sure of the lung from which the blood comes, it is one of the author's most valuable measures, granted no adhesions exist. The procedure is unquestionably very dangerous if carried out carelessly, or without the constant use of the manometer, but in careful hands the percentage of danger should be very small, and while the chief danger arises while giving the preliminary injection, air embolism and other dangerous complications can occur during the course of reinjections. Forlanini's advice that small amounts of gas be injected slowly and under low pressure should never be forgotten now in cases of hemorrhage.

29. **Wassermann and Luetin Reactions in Tuberculosis.**—Seventy-nine of a total of 170 negative Wassermann cases gave a positive luetin reaction, while only 18 out of a total of 28 positive Wassermann cases gave a positive reaction, justifing the conclusion that the luetin reaction cannot be used as a test for syphilis in a tuberculosis sanatorium to displace the Wassermann test.

37 Intussusception, Its Early Recognition. H. Apfel, New York.—p. 781.

35. **Indirect Transfusion in Hemorrhagic Disease in New-Born.**—On the third day of life, Knox's patient nursed well at 9 a. m. and shortly afterward vomited a considerable amount of dark blood-stained fluid. There was no fever and no cough. When seen shortly afterward, the baby was found to be rather sallow, but vigorous. During examination the child passed from 3 to 5 ounces of tarry, blood-stained material, evidently a hemorrhage from the intestinal tract. There was no lesion about the anus. It was at once concluded that this was a case of melena, and transfusion from the mother was determined on. About 50 c.c. of the mother's blood was received into 60 c.c. of sodium citrate solution. With a syringe, about 15 c.c. of this was introduced in the longitudinal sinus and the rest in small quantities intramuscularly into the buttocks. From 12 noon to 3:30 a. m., when the transfusion was completed, the child passed three or four tarry stools, and was greatly blanched, pulse became thready and respiration shallow and the baby seemed about to die. With complete rest, however, the condition slowly improved through the night, and the following morning the child seemed much better. The following day the baby had one bloody discharge from the bowel, not accompanied by any change in pulse or rise in temperature. The material was darker than before and was probably part of the original hemorrhage. The child was hungry and the amount of milk was increased to 6 drams, every two hours. The following day the baby had two yellow stools with some mucus, and the color was further improved. She was given 1 ounce of milk at two-hour intervals during the night. From this time on the child made an uninterrupted recovery, and there was no further bleeding.

36. **Therapeutic Use of Blood Serum.**—A baby, 2 days old, had a movement which consisted of 1½ ounces of clotted blood. Three smaller movements of the same character had previously been passed. The child was pale and its condition critical. The father was fortunately accessible. A needle was passed into one of his veins and 6 ounces of blood removed; 15 c.c. of the blood serum was injected into the baby at 5 p. m. When the child was seen again at 9 p. m. no more blood had been passed and a second injection of 15 c.c. of blood serum was used. A movement the next day contained two small clots of blood, but it was evident from the time the first blood serum was injected that the bleeding had been entirely controlled. This baby went on to a normal development. Freeman also reports four cases in which horse serum was used to good advantage.

46 *Treatment of Pernicious Anemia—Especially by Transfusion and Splenectomy. G. R. Minot, Boston and R. I. Lee, Cambridge.—p. 761.

46. **Treatment of Pernicious Anemia by Transfusion and Splenectomy.**—Of the ninety-six cases of pernicious anemia studied by Minot and Lee, 115 observations may be used for the study of therapeutic procedures. The effect of two different procedures was observed in nineteen cases at times so remote from each other that there could be no confusion of their effects. Forty patients were treated either by no special therapy or by arsenic in some form, and represent "untreated" patients. There are suitable data for study of forty-six different patients transfused in one relapse of each case. Seventy transfusions were given, not counting the transfusions associated with or given at any time after splenectomy. Nineteen patients were splenectomized, with one operative death in a case with a red count below 1,000,000. Ten patients were treated by exposure of the spleen to the roentgen rays. There was, inside of a few weeks, definite improvement beyond a simple filling up with transfused blood in about 50 per cent. of the forty-six patients that were transfused. Very slight improvement occurred in about 13 per cent. more, so that about 63 per cent. of the transfused patients showed at least some improvement beyond that due to the volume of transfused blood; while 84 per cent. of the nineteen splenectomized patients showed definite improvement following the operation. The degree of the improvements following transfusion or splenectomy averaged greater than the improvements in the "untreated" patients. In a time proportionate to that in which the transfused and splenectomized patients showed definite or slight improvement, only about 35 to 40 per cent. of the forty untreated patients showed any improvement at all, though about 80 per cent. of any pernicious anemia patients at some time in their course show some definite improvement. There is no conclusive evidence that the duration of the improvements or clear-cut remissions are any longer in the transfused and splenectomized patients than in the untreated ones. However, there were but 7.5 per cent. of the untreated patients that showed such marked and rapid gains in the same period of time (about a month) as 30 per cent. of the splenectomized and transfused patients did (18 per cent. of the transfused and 46+ per cent. of the splenectomized). The untreated patients formed a similar number of the different types of the disease as those splenectomized and transfused, except that all four cases of the acute type occurred in the transfused group. It is to be noted that the transfused group contained more unfavorable cases than the untreated group, and that ten of the transfused patients died within a month, while but four of the untreated patients did so.

52. **Isolation of Tubercle Bacilli.**—Tubercle bacilli were isolated by Stewart by the Petroff method from 64.8 per cent. of the sputums which were found to be positive by the direct microscopic method. The organism was recovered from 69.2 per cent. of the samples of milk that were artificially infected. Of the milk obtained through the New Haven Health Department Laboratory 8.4 per cent. of the samples were found to contain tubercle bacilli, while none of the twenty-nine samples from the state laboratory gave positive cultures. All the guinea-pigs (thirteen), except one, which were used as control animals died without any visible signs of tuberculosis. Stewart concludes that Petroff's method for the isolation of tubercle bacilli from sputum may be applied successfully to the examination of milk. With slight modifications, the method should prove constant and reliable. The need of such a method for the examination of milk and milk products is apparent.

54. **Effect of Alcohol on Reproductive Tissues.**—Arlitt and Wells found that the administration of alcohol in the food of male white rats for two or more months, in daily quantities of 0.25 to 2.25 c.c., results almost constantly in the appearance of marked degenerative alterations in the testicles. These changes affect the steps of spermatogenesis in inverse order to their occurrence, so that for some time before sterility and complete aspermia result the animal is producing spermatozoa with all possible degrees of abnormality and deficiency. The possible relation of this abnormal spermatogenesis to the production of defective offspring is obvious. Individual rats show marked differences in the degree of change produced by equal amounts of alcohol. The fibrous, interstitial, and vascular elements of the testicle are not affected, except for intertubular edema compensating for tubular atrophy. These experimental observations harmonize with the necropsy findings in human alcoholics. No other tissue was found to be noticeably affected by the alcohol; especially to be marked is the absence of cirrhosis of fatty infiltration in the liver.

56. **Blood Destruction and Regeneration in Hemolytic Jaundice.**—In four animals with a bile duct ureter anastomosis and without disturbance due to obstruction or absorption, the total quantity of bile pigment output during a day under normal conditions varied from 0.0618 to 0.0678 gm. These figures are practically identical with those of Stadelmann (9, 10) but lower than those given by Hooper and Whipple (7), who find that the average bile pigment excretion amounts to about 1 mg. per pound of body weight per 6 hours. In all of Goto's experiments there is definite evidence of a decrease in bile pigment elimination after splenectomy. This is true not only of the elimination when no hemolytic agent is administered, but also when excessive blood destruction is caused. Under the latter circumstances the amount of bile pigment is greatly increased, but never reaches the high level of blood destruction before splenectomy. These observations appear to show conclusively that the absence of the spleen influences the formation of bile pigment. To what extent the influence is mechanical (that is, change in the course of the blood to the liver) and to what extent due to anemia, cannot be stated at present.

58. **Diversion of Pancreatic Juice.**—From the results of Grey's experiments it appears that the presence of a considerable amount of pancreatic juice in the stomach throughout the period of digestion leads only to a moderate decrease in the acidity level of the ingesta in the later stages of digestion. Earlier in the process there is no constant alteration of the acidity level in either direction. The findings, then, serve not only to corroborate the views of Boldyreff, but also to demonstrate the remarkable compensatory activity of the gastric glands under conditions which entail an unusual quantity of alkali in the stomach. In addition the work has shown that when the larger pancreatic duct is properly transplanted into the wall of the stomach, it may remain patent for months. In animals in which this operative procedure has been carried out, the pancreas has been found to undergo no inflammatory or other degenerative changes. This finding is regarded as evidence against the postulation of Hlava that gastric juice is probably responsible for the occurrence of certain cases of acute hemorrhagic pancreatitis.

60. **Diversion of Splenic Blood.**—The splenoreal venous anastomosis made by Burket offered a simple and satisfactory method of diverting the splenic blood into the general circulation because it was easy and produced no gross abnormal intra-abdominal changes, and the vessels normally lay parallel to each other and were readily approximated without tension. The operation was successful in every case. The animals did very well after operation and were healthy and active. No noteworthy histologic changes were observed in any of the organs or tissues. There was no essential change in bile production that could be detected by jaundice. The urine and stools showed no changes.

64. **Studies on Cholesterol.**—In 748 parallel blood cholesterol determinations made by Luden according to Bloor's original method, with sodium ethylate, and Bloor's modification of his method, without sodium ethylate, a constant difference could be observed in the cholesterol values obtained by both methods, lower values being registered by the tests with sodium than by those without. This difference was found to be most pronounced in samples of icteric blood obtained from cases of obstructive jaundice, but a constant slight

difference, ranging from 0.05 mg. to 0.07 mg. could be observed also in normal blood. Luden's observations suggest that parallel cholesterol determinations with Bloor's original method and its modification might furnish valuable information concerning the chemistry of the blood, particularly in cases of biliary disturbance without visible symptoms of icterus, as Bloor's method is extremely simple and could easily be supplemented if desired by the dialyzation method of Hoover and Blankenhorn.

66. **Etiology of Arteriosclerosis.**—Five hundred persons were examined by Warfield for the purpose of showing that the infectious diseases played an important part in the production of arteriosclerosis, but the results of this study showed that they play little or no part in the etiology of this condition

91. **Heart Block in Acute Rheumatic Pericarditis.**—In Christian's experience heart block has been relatively quite frequent in one type of rheumatic cases, namely, where with or shortly following acute articular disturbances the patient develops the typical physical signs of acute pericarditis. In sixteen consecutive cases of this type, heart block has been demonstrated in five and possibly may have been present in a sixth in whom irregularity of pulse was felt. Christian fears that it may have been overlooked in some of the others, though in all but two electrocardiograms were made. Still, block may have occurred on other days than those when electrocardiograms were taken and suggestive evidence of it not be found by detecting any irregularity in the pulse. After all, as the condition is transitory, it is remarkable that it was detected as often as it was in this group. The part played by digitalis in this group is not certain. In one case with block no digitalis was given; in others digitalis did not seem always closely related to the occurrence of the block. In four patients in whom block was not demonstrated digitalis was used, in one case in fairly large amount. From what Christian has seen in the use of digitalis in other cardiac cases, digitalis would not seem to be the chief cause of the heart block in this group. Probably, however, with a rheumatic lesion in the conduction system digitalis has had an added effect on it and led to block where without it block would not have occurred. In this sense digitalis may have been a contributory factor in the occurrence of block. The frequent occurrence of partial heart block in these cases of rheumatic pericarditis emphasizes further the extent of the involvement of the heart in rheumatism and justifies the caution in allowing the patient convalescing from rheumatism to exercise. In Christian's cases the block has not appeared to have influenced in any way the clinical course of the patients' disease. All but one of the patients recovered and a fatal case was one in the group not showing block.

98. **Group Study Method for Pulmonary Tuberculosis.**—Two years ago, the diagnostic section of St. Luke's Hospital, San Francisco, established a method of clinical investigation different from any system hitherto recorded. This difference lay in the extensiveness and completeness of examination as well as in the carefulness and completeness of its records. The method agreed on is as follows: Patients who are chronically ill (average, two years and a half), who have shown no tendency toward spontaneous recovery, are sent to the hospital by their own physicians for investigation. They are then examined by twelve clinicians representing the following departments: pathology, bacteriology, roentgenology, eye, ear, nose and throat, cardiovascular diseases, respiratory diseases, gastro-enterology, urologic surgery, neurology, orthopedic surgery, general surgery and general medicine. Thus each clinician examines each case, whether or not it falls symptomatically into his department. Furthermore, he makes a written report of his findings. The members of the section meet formally each day to discuss the case until all are satisfied with the conclusions. Through the correlation of each clinician's findings, cases are carefully culled and diagnosis is narrowed down to the fewest possibilities; also, in ruling out symptomatology which simulates tuberculosis, the respiratory clinician has been so greatly assisted by the findings of the other departments that he states with conviction his conclusions as found in this paper, for his findings are not that of one man but of one plus eleven others. From the data thus collected, the respiratory clinician presents the diagnostic results of 400 cases examined serially by the group, setting forth the value of the history, physical examination, tuberculin tests, laboratory and roentgen rays reports in coming to a conclusion for or against pulmonary tuberculosis.

It seems that the physical examination gives the most reliable information and for this reason more and more time is now being given to this part of the investigation, an hour often being spent in examination of the chest; the history is of next importance and should be checked carefully and repeatedly, since often at first the questions are misunderstood or their importance is not apparent; the tuberculin reactions can be relied on in only two thirds of the positive cases and in 96 per cent. of the negative cases. The roentgen ray gives no positive evidence in nearly 50 per cent. of the cases, gives less positive evidence than the tuberculin test, and is of no value except in a negative sense, until extensive pathologic changes have taken place, this occurring in most cases long after the symptomatology and physical examination are well marked. The examination of the sputum from the pathologic standpoint is positive only about once in ten times, and too often this pathologic conclusion gives the attending physician a feeling of false security that the case is negative, much valuable time for the patient thus being lost.

7 *Case in which Markings of Nutrient Canals of Ilium were Mistaken for Fracture. A. K. Smith-Shand.—p. 346.

2. Diffuse Traumatic Aneurysm in Surgical Neck of Humerus.—In Knaggs' case a bullet had passed through the surgical neck of the left humerus. The wound of entry was behind the shoulder over the posterior fibers of the deltoid, and the bullet had passed out through the center of the upper part of the biceps. Both wounds were healthy, and apparently superficial, when the patient was admitted. About four weeks later the man had a bad night owing to a great deal of pain in the shoulder, and the next morning pulsation was first detected about an inch above the exit wound. Examination showed that the upper part of the shaft was considerably enlarged, and that this enlargement was the subject of expansile pulsation. The main artery was normal as it coursed over the internal aspect of the swelling. No bruit could be made out, and there was no thrill. The roentgenogram showed a large irregular aperture in the surgical neck, with comminution of the internal surface, the fragments being displaced as if they had been forced outward by the explosive effect of the bullet. Ten days later an enlarged gland was noticed in the supraclavicular fossa. The general swelling of the shoulder that had followed the wound had now completely subsided, and the increasing expansion of the bone showed as a definite rounded tumor about the size of a cricket ball, altering the normal contour of the limb. There was a general agreement in a diagnosis of rapidly growing endosteal sarcoma but at the operation nothing was seen that looked like tumor tissue. A mass of black clot was evacuated. This was followed by very free arterial bleeding, and the cavity was at once firmly packed. After weighing the pros and cons in the case an interscapulothoracic amputation was performed by Littlewood's method, that is, from behind. A rapid recovery followed. Knaggs says that there can be no doubt that this was an instance of a traumatic aneurysm occurring in the interior of the humerus, and that it probably ruptured and became diffused when the patient suffered for the first time since his admission with severe pain in the shoulder.

5. Projectile Fracture of Bones of Extremities.—The authors summarize their observations as follows: From the surface of a divided or fractured bone exposed to infection, bacteria may penetrate to the deeper parts. In an untreated fracture, penetration is apparently unlimited. If the dead bone on the surface of the fracture is removed early, penetration is much reduced, and may not occur at all. Penetration, particularly of anaerobes, is greatly increased by reduction of the circulation through the injured bone. Penetration is increased by obstruction to drainage, either of the bone or of the soft parts. The order of frequency and power of penetration of the bacteria found is: (1) streptococcus; (2) staphylococcus; (3) anaerobes; (4) *B. coli.* The rate of penetration is at its maximum during the first few days. In the material examined, no difference in reaction to penetration has been noted between cancellous bone and the marrow of the shaft. Bruising—an invariable accompaniment of projectile fracture—does not appear to facilitate penetration if the surface layer of débris is removed and drainage established. In a septic fissure, growth of bacteria is progressive and may lead to infection of a distant part, for example, a joint. Dissemination of infection throughout a bone takes place by penetration from its walls.

7. Normal Markings Mistaken for Fracture.—This case is of interest in demonstrating that it is possible to mistake an unusually large nutrient artery in the ilium for a fracture of that bone; further, it brings out the fact that the nutrient arteries of the ilium, whatever their point of entry, invariably converge to a common meeting point which may be considered the true primary center of ossification of that bone.

15 Spontaneous Evacuation of Shrapnel Bullet in Lung by Expectoration. R. M. Leslie.—p. 648.

9. Cause of Death from Shell Shock.—This is said to be the first description that has been given which serves to explain (1) sudden death in shell shock, and (2) the clinical symptoms which persist for some time after the commotion of the brain in nonfatal cases. The brain was extremely congested, and on each side of every superficial vessel there was an ecchymosis. There were a number of minute punctiform hemorrhages at the terminations of the smallest vessels on the surface of the brain. The whole brain was soft but not markedly edematous. The cerebrospinal fluid appeared to be blood tinged. There was considerable ecchymosis on each side of the great sinuses of the skull. There was no large hemorrhage found and no small intracerebral petechiae. There was no gross lesion of the viscera, which would have been a cause of death.

13. **Germicidal Efficiency of Certain Antiseptics.**—The main facts disclosed by Dakin and Dunham's series of experiments are as follows: (*a*) The rapid and complete disinfection brought about by solutions (one volume) of members of the chlorin group of antiseptics of the strength commonly used in the treatment of wounds, when added to heavily infected blood serum muscle extract mixture (two volumes). (*b*) Under similar circumstances, solutions of acriflavine, proflavine, brilliant green and malachite green failed to sterilize in six hours mixtures which the chlorin antiseptics sterilized completely in five minutes or less. The authors believe that the statements of Browning and his colleagues as to the relative germicidal efficiency of chloramin-T and other antiseptics of the chlorin group compared with brilliant green, malachite green, and acriflavine, are incorrect, and that their mode of testing the germicidal action of the substances studied by them leads to results which are radically misleading.

14. **Detection of Amebic Dysentery Carriers.**—Emetin bismuth iodid when given in a powder generally causes nausea and vomiting. In order to overcome these conditions three preparations of the drug were tried by Jepps and Meakins. These were experimental preparations made by three different firms, and were submitted to the authors for trial. They were all in tablet or pill form, and were either mixed or coated with some material supposedly insoluble in the stomach. In all, twenty-three courses of treatment were given with these preparations. In no case was nausea or vomiting produced, but in eight cases (35 per cent.) severe diarrhea and abdominal cramps occurred. Some looseness of the bowels was observed in all cases in which the drug appeared to have any action. Different measures of success were obtained with these different preparations. With the first preparation there were eight cures out of twelve patients treated, or 66 per cent. With the second there were no cures, while with the third there was only one cured out of four patients treated, or 25 per cent. Of the three preparations, the first was the only one which gave sufficiently good results to justify its use in preference to the drug given in powder. But even the proportion of cures with this preparation is not sufficiently high to warrant its general use. The objection to the use of emetin bismuth iodid in powder, given in a cachet or capsule, has been the occurrence of nausea and vomiting. The authors have treated eleven patients with cachets, and these symptoms occurred in all of them. The drug was given with a hot drink at 9 p. m., after the patient was in bed. The time of the vomiting after the drug was taken varied in different individuals.

It is evident that the nausea and vomiting occurs most frequently after the stomach is presumably empty. These symptoms fortunately did not persist during the whole course of treatment. The toxic symptoms disappeared after a time as if a tolerance had developed. Eleven cases were treated with emetin bismuth iodid in cachets of 3 grains each. Ten cases (91 per cent.) were cured after twelve daily doses. One patient who was not cured had previously resisted three courses with the first preparation. The results obtained with the drug administered by this method are much more encouraging than those obtained with any of the other preparations. All the patients treated were suffering from symptoms of irritable heart. Any possible effects of the removal of the *E. histolytica* infection on the symptoms of this condition were carefully looked for. Of the twenty cases which were cured, eleven (55 per cent.) showed a conspicuous improvement, while nine (45 per cent.) showed little or none. The degree of improvement was determined by their increased ability to perform graduated exercises without untoward symptoms. Patients who, before treatment, showed severe symptoms after performing mild exercises could afterward accomplish the more advanced exercises with comparative ease. This confirms the previous conclusion that the removal of a coexisting infection may lead to the alleviation of symptoms of irritable heart.

21. **The Interauricular Interval.**—Etienne and Mondelange have been studying with cardiography the asynchronism between the auricle systoles. Their eighteen tracings confirm conclusively the interauricular interval in man as it has been established in the horse and dog. The cardiogram gives more correct findings in this matter than the electrocardiogram; it demonstrates that the effectual systole of the right auricle precedes the left systole.

22. **Strophanthus Derivatives.**—Vaquez and Lutembacher report extensive clinical study of the indications and contraindications for intravenous injection of strophanthus derivatives and of ouabain in particular. The latter is a very potent drug, but when used wrongly is dangerous; fatalities have been known to follow its use. Twelve clinical cases are described in detail with the tracings.

32 *The First Devices to Aid the Amputated. Baudet.—p. 245.

24. **War Fractures with Displacement of Bones.**—Delorme is medical inspector general of the French army, and he here presents the results of research on cadavers with fractures and displacement of the stumps or of broken off portions. The differences between these war fractures and ordinary fractures are great as he shows for each of the large bones in turn, with illustrations. Certain general laws are apparent through all, and roentgenoscopy is constantly throwing new light on the subject.

25. **Specificity of Antiseptics.**—Taylor remarks that two years of observation of persisting infection in several thousand cases of war wounds have convinced him that this branch of medicine has made but little progress. Even today it is still impossible to say "This is the proper method to be followed in treating an infected wound." He attributes this to the scant attention hitherto paid to the individual characteristics of the different antiseptics in relation to the characteristics of the bacteria in the wound. We probably

will have to give up the hope of a general antiseptic; we must apply the specific antiseptic for the specific bacteria in the wound. His tabulation of the germ content week by week in different wounds with different bacteria predominating shows more streptococci, *for instance, by the fifth* week than were present the first week in wounds treated with cresol or with hypotonic salt solution. With the pyocyaneus, the figures the first and fifth weeks were respectively 50 and 60 in wounds treated with quinin; 33 and 55 with Dakin's solution; while, treated with acetic acid, the number of germs dropped from 35 the first week, 22 the second, 11 the third, to zero the fourth and fifth. With staphylococci, the figures under cresol were, the first week, 73 and 40 the fifth week; under Dakin's solution they were 77 the first and 40 the fourth week (fifth week not mentioned). With the aerogenes capsulatus, under dry dressings the figures were 2, 2, 3, 7 and 4 on successive weeks, while in the wounds dressed with quinin, from 20 the first week, the figures were constantly zero in the following weeks . These were the most striking findings in his experiments with all the various kinds of antiseptics used in the innumerable cases. The average with all other antiseptics, beside those specified above, showed a higher figure for the germs the fifth, in comparison to the first week, except in the case of the aerogenes capsulatus in which the figures were respectively 12, 7, 6, 7 and 1 on successive weeks.

29. **The Duties of the "Technical Adjunct."**—Louste refers to the general technical supervision of barracks, camps and cantonments and the troops themselves. The office of technical adjunct has been created for the purpose, as a kind of medical efficiency engineer. It presupposes the absolute confidence of the chief of the army medical department who entrusts him with full authority as his representative. It also presupposes the close collaboration and support of the commander of the forces. Louste is himself *adjoint technique* for the fourth district. When he entered on his duties he insisted on a general meeting of the staff at which he explained the importance of close collaboration between the military and the medical departments, the resources which the laboratories can furnish, and the necessity for uniform control, and of a constant and identical surveillance. He here presents his report on conditions in the barracks, camps, etc., with suggestions for improvement. Among the minor improvements which he has brought about, he mentions the great change for the better when the men were able to keep up a vegetable garden; the hundreds of pounds of lettuce, carrots, beans and cabbage thus raised at Laval gave the troops stationed there actual homelike food, not merely the army ration. In regard to drinking water, he says that the rule to boil the water cannot be applied at present on account of the scarcity of coal. Well cared for Chamberland filters are used where they are already on hand. Chlorination of the water seems to be the simplest method for purifying it for barracks and camps, but it must be in the charge of experts, provided with a double set of receptacles.

He remarks that in dealing with the local civilian authorities it should be a principle not to criticize a condition unless one has a simple and practical solution of the problem ready to propose. He deplores that in the education of army officers they are not given training in matters concerning the hygiene, physiology and health of the men in their charge. "Even with all the progress realized," he remarks, "the commanders of the forces are not always in close sympathy with the chiefs of the medical departments. If this regrettable gap could be filled up, the medical officer and the military officer would understand each other better, and close cooperation between the commanding officer and the medical department would be not only an official regulation and on the order of the day, but it would be a living reality, to the great benefit of the country which would find in the army a new source of life based on reciprocal confidence and esteem."

30. **The Eyes as Affected by Vaccination Against Typhoid.**—Summarized in the review of ophthalmology in 1917, abstract 37, p. 1914.

31. **Restorative Surgery of the Genital Organs.**—De Sard gives a profusely illustrated description of four cases in which the external organs of procreation and urination were restored to more or less satisfactory aspect and functioning after destructive war wounds.

32. **The First Aids After Amputations.**—An illustration shows the simple device with which after amputation of the forearm, a fork, spoon or hook is fastened in a reenforced plaster cone, wound with gauze to form a cap which fits over the stump and is held in place by a strap buckled to a cushion on which the elbow rests. With various modifications of this principle the man can use his arm for numerous purposes. A similar temporary plaster dressing, with a lathe incorporated, can serve for the leg, letting the stump hang loose.

35 *Anesthesia and War Surgery. D. Baruch.—p. 928.
36 *Foreign Bodies in the Brain. H. Burger.—p. 936.

33. **The First Dressing of a War Wound.**—Vincent insists that the interval before infection gets an actual start in a wound is shorter than most believe. Instead of eight or twelve hours, the damage is done in six or even four. He knows of cases of gas gangrene developing in six hours. In certain regions around Verdun, the perfringens was found in every wound. Crushing of tissues from one to eleven days after experimental inoculation of guinea-pigs with nonpathogenic perfringens was followed by development of gas gangrene. He cites further other data to sustain his plea for immediate sterilization of a war wound at the first dressing, especially when the wounded are coming in in large numbers. "When a man is wounded in war, moments are precious. Hours are worth days; hours are worth lives." In many years' experience in Madagascar, from 1894 on, and again in the present war, he has never found anything to equal the efficacy of calcium hypochlorite plus nine parts boric acid for prompt sterilization of wounds. Extensive research always brings him back to this mixture as more effectual than all others. The wound is powdered well with it, and it is insufflated into all the recesses and into seton wounds, running the nozzle of the atomizer deep into the wound. This dry powder is slowly dissolved by the secretions in the wound, taking three or four hours for this. This holds the germs in check, and the man reaches the field hospital with his wound in the same condition as when the wound was first dressed. "Merely to apply an aseptic dressing on the battlefield and at an advanced dressing station is too platonic for the formidable infections stalking the wounded. This dry powder treatment does not interfere in the least with whatever measures are to be taken later, when the man reaches the field hospital." His experience is confirming more and more the effectual sterilization realized by thus powdering the wound thick with a mixture of 10 parts of calcium hypochlorite to 90 parts boric acid passed through a No. 70 sieve.

34. **Reflex Paralysis and Contracture After War Wounds.**—Molhant presents evidence, from his experience at the special hospital for the nervous affections of the war, to the effect that so-called reflex paralysis and contracture are in reality usually the manifestation of a definite and irremediable organic injury. This injury is a terminal neuritis of the sensory nerves, but the manifestations deceptively simulate those of hysteria, and the latter may be superposed on the organic lesion. The symptoms may be of the hypertonic order: reflex irritability; or of the hypotonic order: reflex paralysis. He explains how the motor and sensory fibers are associated throughout except where they leave the spine, and at their terminals. Blocking of the peripheral nervous impulse at either of these points may generate motor disturbance of purely reflex origin, although the lesion which causes the blocking may involve the sensory fibers alone. The terminals of the deep sensory fibers are in the soft parts surrounding joints and in the periosteum. Injury of any of these injures the sensory terminals, and may irritate to excessive functioning or may paralyze. The paretic reflex may be manifested by paralysis or contracture, but the con-

tracture is due merely to excessive functioning of the antagonist muscles. Applying a tourniquet to the root of the limb abolishes the contracture, and we can see that the trouble is really a paralysis with the antagonists getting the upper hand. Instead of keeping these patients on in the hospitals indefinitely, trying to cure their "hysteria," the organic base of their affection should be recognized early and they should be fitted with prostheses and discharged from the ranks or given light duty. He devotes several pages to description of means by which these organic disturbances can be differentiated.

35. **Anesthesia for the Wounded.**—Baruch gives some tracings which show that the suffering induced by an operation is unconsciously perceived by the nerve centers notwithstanding deep chloroform narcosis; this is rendered evident by the immediate intense fluctuations in the blood pressure in the carotid artery. Under the same conditions, but with the trunk nerve blocked with novocain, the blood pressure was not modified. He agrees with those who maintain that the pain excitations transmitted to the nerve centers, especially to those in the bulb, are the effectual cause of operative shock. Faradization of the exposed sciatic nerve in the chloroformed dog will convince the most skeptical. Local anesthesia should be given the preference always when at all practicable, namely, infiltration or regional anesthesia. This blocks the nerve, sparing the nerve centers the strain from perception of the pain, while the anesthetics employed are in such weak solutions that they are free from toxic action and do not modify the functioning of the emunctories. Of equal importance is the fact that they leave intact the patient's capacity for reaction.

36. **Foreign Bodies in the Brain.**—The conclusions of this review of the present consensus of opinion in regard to management of projectiles in the brain are to the effect that the ventricles and the base of the brain must still be regarded as regions inaccessible to surgery. Otherwise, the majority seem to agree that cautious extraction of the projectile at once, through the passage made by its entrance, is the preferable procedure.

Napoleon used to say, "I do not believe in medicine, but I believe in Corvisart"—his physician. His definition of medicine has seldom been surpassed: *l'expérience chez un homme supérieur.* Burger reiterates that experience is a better guide than theory, and that although there are a certain number of men, apparently doing well, who for a year or two have been carrying a bullet, fragment of shell, or shrapnel ball in their brain and seem to tolerate it perfectly, yet the projectile remains always a constant menace for the health, besides the man's worry over its presence. Experience has further demonstrated that the extraction should be done at once. A secondary operation for an apparently well tolerated foreign body is not advised. The work should be done at the first operation, at the same time as all splinters of bone are removed.

44 Apparatus for Extension of Fractured Humerus. Stern and Bentami.—p. 348.

41. **Chronic Colitis.**—De Pury deplores that too often it happens that chronic intestinal trouble is ascribed to the appendix alone. Appendicectomy without inspection of the adjoining intestines is liable to leave the main source of trouble unmolested. Nine times in ten the cecum is diseased along with the appendix. Particularly important is the perityphlitis with dilatation of the cecum and chronic appendicitis, with more or less constriction of the angle of the colon just below the liver. It is at this angle that the inflammatory phenomena are most frequent and most pronounced, and adhesions most abundant. This is where the trouble starts which brings the appendicitis in its train, and it may set up cholecystitis, pancreatitis, duodenal or gastric ulcer and even disturb kidney functioning and favor development of tuberculous lesions in the kidneys or abdomen, and entail the whole series of gastro-intestinal atonies. Aside from the inflammatory phenomena on the part of the appendix, perityphlitis demands operative intervention whenever the symptomatic trilogy, pain, constipation and autointoxication, persist rebellious to systematic medical and dietetic measures.

The operation should aim to restore the regular open sewer throughout the bowel. The enlarged cecum forming a pocket where feces stagnate must be restored to normal size and shape; all adhesions along the small intestine and colon must be broken up, and any kink in the colon must be straightened out. He gives a detailed description with the roentgen findings in four typical cases of the kind. Conditions were restored to clinically normal by taking up lengthwise folds in the cecum until the lumen was reduced to normal size and shape. He reiterates that the stagnation of feces with secondary infection is always the primary trouble, starting the inflammation in the wall of the intestine, whence it is liable to spread in any direction, but almost inevitably it entails atony of the cecum which stretches, just as the bladder stretches when its wall becomes infected. With both, along with the atony, there is liable to be spasmodic stenosis. The insidious development of the whole trouble and the mildness of the symptoms at first are misleading, so that the nature of the trouble is not recognized. Courses of treatment for neurasthenia, dyspepsia, etc., give no relief, and not even appendicectomy. Uncontrollable vomiting after eating may occur from retrograde peristalsis on account of constricting adhesions or kinking of the bowel, usually both. Vomiting from retrograde peristalsis from this cause is not uncommon in young girls. The clinical picture deceptively simulates that from pylorospasm from dilatation of the stomach or gastric ulcer or stenosis of the pylorus or irritative dyspepsia. In most cases nothing but roentgenoscopy will permit the correct diagnosis. This alone will reveal that in many cases of neurasthenia, etc., the whole trouble is merely constipation from constriction or kinking of the colon, which renders it impossible for it to empty itself completely.

43. **Posterior Adenoiditis.**—Rosenthal and Cheville assert that further research and experiences have confirmed anew that the primary and fundamental seat of meningococcus infection is in the rhinopharynx, a posterior adenoiditis. But whatever its scientific and pathogenic importance, this primary lesion causes no pain and hence is overlooked. Smears from the rhinopharynx may give cultures and cell counts which throw light on many clinical cases of serious infection, and point the way for effectual treatment by sterilization of this primary focus.

45. **Loss of Memory in Malaria.**—De Brun of late has found amnesia one of the most characteristic features of malarial polyneuritic psychoses. Almost a third of the malaria patients

in his service at the Rueil hospital have more or less impairment of the memory. With a primary attack, the memory of that period may be permanently a complete blank. One of his patients had no remembrance of anything connected with his stay in the hospital and for several months thereafter. The malarial subject may also present retrograde amnesia, unable to remember certain periods in his previous life, possibly back into childhood. Some of the men have forgotten completely a foreign language which they spoke fluently before the malaria. Others have forgotten historical events and geography, or lost their knowledge of music or mathematics. Skilful electricians cannot recall the most elementary principles of physics and electricity, and are unable to instal the simplest electric device. Artisans have forgotten the uses and names of their tools.

The situation is aggravated further by fleeting phases of loss of memory for the ordinary acts and duties of life, amnesia for happenings since the sickness, inability to concentrate the attention. Some complain of headache and visual disturbances whenever they try to focus their attention on anything. They are unable to read with attention, and forget almost at once what they have read. One of the educated men was unable to count beyond ten. Sometimes they write and mail a letter and later in the day write and mail another just like it. They even forget whether or not they have had their meals. Some of the men have been sent to the guardhouse for failing to do what they had been ordered to do. The dangers of such lapses of memory are peculiarly acute in the case of officers. The men acquired the malaria in the Saloniki region, and they do not stay long enough in the Rueil hospital for the ultimate outcome to be known.

48. **Curability of Chronic Tuberculosis of the Kidney.**—Hallé reiterates that removal of the tuberculous kidney usually leaves foci elsewhere in the body. The mortality in the first few years after the operation is still quite high. Pathologic anatomy has demonstrated that there are two forms of tuberculous processes in the kidneys, the closed parenchymatous process, which is spontaneously curable and relatively benign, and the open tuberculous pyelitic process which generally keeps up a progressive and destructive course. The process may be of the first type at first but finally merge into the second type. In the first type, early and active medical treatment would hasten the favorable outcome, but this type is rarely recognized. The second type, if the course is rapidly progressive, calls for nephrectomy at once, but if the course is more benign and slow, expectant treatment is justified, hoping for spontaneous retrogression which occasionally occurs. When an operation is required, nephrectomy is called for. Partial nephrectomy is futile unless for a closed parenchymatous process, and this does not require operative treatment at all.

50. **Slow Malignant Endocarditis.**—Debré remarks that this disease is not sufficiently known and often it is not even suspected. Even when the endocarditis is diagnosed, the physician fails to realize that the ups and downs slowly progress to an inevitably fatal outcome. It does not seem to be contagious, but series of cases have been known at a few points. The streptococcus responsible for it is not usually pathogenic. Possibly meteorologic conditions rouse it to virulence. It has been observed in children and at 52 and 53, but usually young adults are the victims. Nearly all have a history of acute articular rheumatism in childhood, entailing a chronic valvular trouble. Another constant finding is that some mild tonsillitis or laryngitis or attenuated genital infection has directly preceded the endocarditis lenta. This evidently exalts the virulence of the germ and favors its entrance into the blood stream. The loss of strength and flesh, the pallor, irregular fever and slight chills are generally ascribed to influenza. Some joint or joints may swell and a return of the articular rheumatism is surmised. This condition may keep up for weeks, and tuberculosis may be suspected or some blood disease. There is nothing to suggest active endocarditis until finally the tendency to purpura, enlargement of the spleen, the joint and valvular troubles and the discovery of the streptococcus in the blood stream aid in differentiating the disease. There may be periods of improvement, but the trend is inexorably downward. The fatal termination is generally due to some embolic softening of the brain or cerebral hemorrhage from rupture of an aneurysm, or coronary embolism or gangrene of embolic origin. The disease may prove fatal in a few months or not until after two years.

51. **Intravenous Sugar Solution in Septicemia.**—Audian and Masmonteil state that their experience has been constantly favorable with intravenous injection of an isotonic solution of sugar in treatment of septicemia. Where the leukocytes numbered from 5,000 to 7,000 before the injection, afterward the count jumped at once to 25,000 in less than a half hour, and kept at this level for two or three hours, and even then did not decline below 16,000. The polynuclears formed 80 to 90 per cent. of this hyperleukocytosis. The reaction seems as intense as after injection of colloidal metals. The temperature runs up a little, with a chill, followed by sweating, like a malarial attack. Induced hyperleukocytosis is regarded by many as the only rational treatment of infections to date. The sugar solution, besides, provides nourishment and has a stimulating influence on the kidney cells, starting up diuresis. The solution must be isotonic: 47.6 per thousand with glucose; 103.5 per thousand with saccharose, or 108.9 per thousand with lactose. From 300 to 500 gm. have to be injected before the leukocyte reaction is realized, but on repetition in the graver cases they do not hesitate to inject 1,000 or 2,000 gm. during the day, fractioned. The leukocyte count is the guide; they inject enough to keep it about 25,000. A severe chill during the hour following the injection is sign that this limit has been reached. This treatment has proved very useful for the septicemia after war wounds. Sometimes two or three injections of 500 gm. will bring the temperature permanently to normal. In desperate cases the amounts can be larger than this and kept up for ten or twelve days or longer if necessary. They never noticed any untoward by-effects but found it necessary to keep up the treatment four or five days after defervescence. This method of treatment applies also to erysipelas, rheumatism, etc., and they are going to try it in infectious diseases.

Correspondenz-Blatt für Schweizer Aerzte, Basel

October 27, XLVII, No. 43, pp. 1425-1456

53 *Effect of Antipyretics on Fever Center. A. Lüthy.—p. 1425.

55 *Treatment of Diabetes. R. Stähelin.—p. 1457.
56 Tumors of Knee Joint Capsule. G. A. Guye.—p. 1474.

53. **Effect of Antipyretics on Fever Center.**—This communication from the Pharmacology Institute of the University of Zurich reports the results of research on the prolonged administration of antipyretics in fevers. With fever of bacterial origin, the drug does not seem to modify the reacting power of the temperature center. As soon as the drug is stopped, the temperature rises again proportional to the degree of the intoxication. On the other hand, if the rise is the result merely of functional irritation of the region of the fourth ventricle, regular administration of antipyretics materially reduces the excitability of the temperature center. This may aid in differentiating in dubious cases.

54. **Nitrobenzol not an Abortifacient.**—A number of cases of poisoning from nitrobenzol are on record in which the drug had been used to induce abortion. Some of them terminated fatally, as in a case described here by Spinner. But only one instance is known of abortion having been induced by this means alone, while seven deaths are known in the sixteen cases cited from the literature. The amounts taken in the fatal cases ranged from a tablespoonful or a swallow to 100 gm. In the one reported successful case the assumed pregnancy may not have actually existed. Cyanosis may be the first symptom, and the odor reveals the cause. Recoveries are on record after ingestion of 100 or 400 gm. The drug is an active poison for the blood, besides irritating and then paralyzing the nervous system.

55. **Treatment of Diabetes.**—Stähelin reiterates that it is actual malpractice to leave a patient with any sugar in his urine when by any means it is possible to banish it permanently. As long as there are even traces of sugar in the urine

there is more or less hyperglykemia, and hence always a menace of gangrene or carbuncle, besides the constant danger of the diabetes progressing to a severe form. By freeing the urine *permanently* of sugar, the *tolerance* for carbohydrates gradually increases. Determination of the amount of carbohydrates the patient can assimilate is a tedious matter for both patient and physician, but it is indispensable. The urine has to be measured and tested daily for the sugar content, and this kept up for several weeks. The patient has to be taught how to collect and measure the urine; he must have a collecting vessel and scales to weigh his food. Stähelin gives tables of the findings over a month or two in some typical cases on ordinary diet, on suspension of carbohydrates, and on their gradual resumption. Drugs have little influence on the glycosuria, and *only in doses that do direct harm* otherwise, but every day new proprietaries are advertised for diabetes, and not only diabetics but some physicians are misled by them. Tabulation of the findings day by day shows plainly that none do any good. If a liter of any kind of a decoction is drunk before retiring, the percentage of sugar in the night urine will certainly drop, but merely because so much water is being voided to dilute it. The patient is convinced that he has improved under the tea drinking, and frequently the physician shares his mistaken impression. The dangerous feature of this mistake is that the really important thing, the dietetic restrictions, is neglected in consequence. The careful working out of the dietetic measures and enforcing them, regardless of everything, usually improve the disturbance in the metabolism to an extent equivalent to a complete cure, and in any event increase the strength, and enable the patient to live for years or even decades in comparative health.

October 25, No. 85, pp. 1137-1144

58 Removal of Polyp in Knee Joint. N. Federici.—p. 1137.

October 28, No. 86, pp. 1145-1160

59 Remuneration for Medical Certificates. E. Villa.—p. 1159.

57. **Roentgen Treatment of Malaria.**—Pais declares that roentgen treatment modifies essentially the course of malaria. Small doses in a first attack attenuate the disease, while large doses change the cycle of the fever. It seems as if the new generations of parasites display exalted virulence under the influence of the radiation. Chronic malaria rebellious to quinin may yield completely under the exposures, or the *infection may* be so modified that quinin may regain its potency. Among the fifty patients thus treated the disease seems to have been arrested in nearly all, and the spleen has subsided to its normal outlines.

Pediatria, Naples

March, XXV, No. 3, pp. 129-192

60 Abscess in Liver of Boy of Eight. R. Jemma.—p. 129.
61 *Cirrhosis of the Liver in Child with Inherited Syphilis. O. Pentagna.—p. 140.
62 Case of Cerebral Bilateral Flaccid Paralysis. R. Vaglio.—p. 151.

61. **Cirrhosis of the Liver in Child.**—The child was 2 years old when symptoms of cirrhosis of the liver developed and proved fatal in less than a year. The necropsy findings confirmed the assumption of inherited syphilis. Mercurial treatment came *too late*; *the liver* had been already irremediably damaged when the child was first seen.

68 *Plastic Operations on the Esophagus. G. Razzaboni.—p. 417.
69 Malignant Edema without Gas Production. I. Scalone.—p. 425. Continuation.

63. **Diagnosis of Pulmonary Tuberculosis.**—Murri protests against a recent ruling by the authorities to the effect that suspects must go to the hospital for thorough examination. He declares that any one skilled in recognition of pulmonary tuberculosis can rely on the clinical findings, examination of the sputum and roentgenoscopy. Long study of the case is superfluous, as a rule.

64. **Serotherapy in Meningitis.**—Capogrossi relates that in twenty-five of his twenty-seven cases of meningococcus meningitis last year, he resorted to intraspinal serotherapy according to the usual technic. The two others were injected with their own serum. The prognosis can be regarded as favorable when the patient is young, and the cerebrospinal fluid is milky and under high pressure, with few germs, and these all intracellular. In such cases recovery is frequent after lumbar puncture alone; the organism seems able to generate its own antibodies under these conditions. The evidence seems to favor the assumption that the meningococci get early into the blood and linger there for some time. This and other data cited suggested the possibility that autoserotherapy might prove effectual. He tried it in two cases in which the cerebrospinal fluid was so purulent and thick that it would not flow. About 7 c.c. of the man's own serum was injected intraspinally twice in one case, but the man died the third day. In the second case, 20 c.c. of the cerebrospinal fluid was evacuated and 10 c.c. of autoserum was injected. The fever subsided at once and within a week the cure was complete. The serum was obtained from 100 c.c. blood drawn from the elbow. It was kept on ice after clotting at room temperature. The autoserum was heated to body temperature before being injected. The venesection should be done at once as soon as the diagnosis is certain. When fresh antiserum is not available, this autoserum might answer the purpose. It certainly is a harmless procedure. In protracted cases, it might prove a valuable adjuvant, when there might be fear of anaphylaxis with continued use of the commercial *antiserum.* The blood in such cases has probably elaborated considerable amounts of spontaneous antibodies, and injecting them into the spinal canal places them just where they are needed.

66. **Operative Treatment in Banti's Disease.**—Losio reports a case which illustrates anew the benefits from splenectomy plus omentopexy, even in advanced cases of Banti's disease with cirrhosis of the liver. His patient was a woman of 58.

67. **War Wounds of the Knee.**—Petrilli relates that wounds of the knee have formed nearly 3 per cent. of the wounded in his service. The wound healed aseptically in 49.2 per cent. of the total 126 cases. In the much infected cases, he keeps the joint open, the exposed bones temporarily flexed and dislocated until the sepsis is conquered, the patient lying prone to facilitate draining, at least for the first few days.

68. **Plastic Operation on the Esophagus.**—Razzaboni gives an illustrated description of the results of his experiments on dogs. He resected through a subhyoid incision a portion of the wall of the upper esophagus, embracing about half its circumference, leaving a defect the size of an Italian penny. This defect was then closed with a flap taken from the rectus muscle in such a way that it included the aponeurosis, muscle fibers and peritoneum. Two of these flaps were prepared and placed in warm physiologic solution while the laparotomy incision was sutured. The flap was fastened to the wall of the esophagus with a marginal interrupted suture, done with the finest silk, the peritoneal surface facing the lumen. The second flap was then sutured over this, the peritoneal surface facing outward, the suture thread passing only through the outer layers of the esophagus wall. The eight dogs thus treated demonstrate the feasibility of the procedure. The continuity of the esophagus wall is restored and the stenosis left is not sufficient to prevent adequate feeding.

73 *Indications for Evacuation of the Uterus in Severe Pneumonia. C. P. Colistro and J. C. Carlevaro.—p. 547.

70. **Herpes Zoster.**—Boix devotes a hundred pages to this exhaustive study of the nature and pathogenesis of zona with reports of a number of unusual cases. In one a four-day infant developed herpes zoster on the right side. In another a woman had intercostal zona a week or two before delivery and the child developed intercostal zona at the second month. This is the only instance of which he has knowledge that suggests possible direct contagion. He cites Pugliesi's case (1891) of general febrile herpes zoster in a young woman, also Boulland's case of bilateral zona complicated with generalized herpes, and Landouzy's case in a physician who has had 100 attacks of herpes since severe zona in his student days. These and other data cited justify the assumption that zona is not exclusively a nerve or skin disease but a combination of both. It is not a morbid entity but merely a clinical syndrome from the combination of the change in the nerve, which may be local or general, old or recent, and the infection, local or general, acute, subacute or chronic, the determining cause of the eruption. The nerve changes and infection may occur simultaneously, as is evident in certain cases of traumatic zona. The different forms of zona are merely different manifestations of the same morbid action, which requires for its production a transient or chronic change in the nerve and some infection which is far from specific although bearing the general designation of herpetic. The unicity of the zona syndrome seems beyond question. Among the cases reported is one in which the zona started in the eye and involved the two superior branches of the trigeminal nerve on the paralyzed side of a woman of 60 with inherited severe nervous taint. In another case the intercostal zona was from a nerve compressed by a diseased bronchial gland in a girl of 8 recently recovered from measles and whooping cough. The vesicles extended down on the fingers. In two other cases in children, inherited syphilis or abdominal tuberculosis evidently afforded a predisposition. In none of the four child cases mentioned was there any pain from the zona. The article is in French.

71. **Traumatism in Psychiatry.**—Rossi is chief of the national insane colony, and he here discusses whether it is possible for mental disease to develop from traumatism alone and whether mental disease after a traumatism differs from that of other origin. He analyzes what has been written on the subject and says that there can be no doubt that there are certain mental clinical pictures which do not need more etiology than a traumatism to explain them, whether the trauma affected the brain directly or not. In others the traumatism may have been merely the provocative cause, of secondary (although of decisive) importance. Traumatism should not be given a higher place in the clinic of the brain than in the clinic of other regions of the body. In respect to the medicolegal responsibility for the traumatism cause, experts should be guided by the general rules for common accidents.

Traumatism can be included in the etiology of mental affections as a determining, occasional or predisposing cause. When it is the determining cause, the symptoms induced are those of denutrition, inhibition or destruction, which induce the clinical pictures of neurasthenia, confusional states or simple demential conditions, according to the severity and the evolution of the traumatism. When the traumatism is merely the occasional cause, it may contribute to the flaring up of latent affections or induce, in association with the symptoms of the other affection, mental symptoms of another character. As a predisposing cause, the traumatism may induce organic lesions which in their healing or evolution, even silent and slow, may serve as an anatomic substratum for organic dementia in the future, or even possibly general progressive paralysis. The medicolegal expert should sift out from the clinical picture the extraneous elements, determine the relations between cause and effect, and draw the prognosis, estimating the degree of mental impairment particularly in relation to the subject's professional and other exigencies.

72. **Advantages of Pyelotomy for Anuria.**—Surraco has only one case to report, but the advantages of incision of the renal pelvis were striking here. The young woman had had anuria for five days from low obstruction of both ureters. The condition was so critical that he made an incision into the renal pelvis without further delay. This permitted evacuation of urine better than if the ureter or the body of the kidney had been opened, while infection could be warded off more effectually and the fistula can be closed at any time with greater ease than when in the body of the kidney or the ureter.

73. **Indications for Instrumental Delivery in Pneumonia.**—Colistro and Carlevaro report two cases in which labor set in during severe pneumonia, and they hastened delivery with forceps. The results were so good that they advocate this systematically in grave bronchopneumonia and pneumonia instead of waiting for spontaneous delivery. The fetus is not exposed to greater danger from the forceps than from the mother's severe infectious disease if left waiting in the uterus. The mother's dyspnea, struggling heart, and fever place her in no condition to stand the stress of labor and delivery. They emphasize, however, that they refer merely to intervention without further danger in itself for the mother.

77 Dissociated Jaundice and Cholemic States. H. Castañeda.—p. 375.

74. **Icterohemorrhagic Spirochetosis in Peru.**—Arce and Ribeyro report a case of what seemed to be Weil's disease in a Japanese who had been in Peru for eight years. He recovered in about a month under a sodium sulphate purge, quinin and tonics. At the eighteenth day of the disease guinea-pigs were injected with 5 or 6 c.c. of his urine, and they developed a similar hemorrhagic infectious jaundice, as also other guinea-pigs inoculated with scraps from their kidneys. The microscope further confirmed in the clinical case and in the animals the presence of the *Spirochaetae icterohemorrhagiae* of Inada and Ito. Their communication is dated Sept. 24, 1917, and they remark that so far as they know, it is the first case of the kind reported in America.

78. **Research on Comparative Histology.**—This study of the retina of a lizard-like amphibian found in the Lake of Mexico is accompanied by a large colored plate of the microscopic findings.

79. **Cicatricial Ectropion.**—Ramirez gives an illustrated description of the various technics in vogue for this purpose, and his own method. With this, two triangular flaps are cut, one below the eye and the other at the outer angle. These flaps are swung around to cover the defect, the result being merely a long curving linear scar.

85. **The Leukocyte Count in Mexico.**—This study of comparative physiology of the blood of persons and animals, acclimated in the valley of Mexico, disclosed a remarkable difference in the staining properties of the leukocytes as well as wide differences in the blood count. The figures are the averages from forty guinea-pigs, fourteen rabbits and large numbers of adults, of all trades and professions and of both sexes. In man the neutrophils predominated, form-

ing 51 per cent. of all the leukocytes, while in the guinea-pig the neutrophils and lymphocytes nearly balance each other. In the rabbit the lymphocytes outnumber the neutrophils nearly three to one, and the eosinophils formed 13 per cent. of the total leukocytes; in the guinea-pig, only 5 per cent.

86. **Disarticulation of the Hip Joint.**—Moreno's profusely illustrated article shows the various steps of the operation for this purpose as he applies it. There is no hemorrhage, as the muscle fibers are not severed but only separated from their attachments, as they run parallel to the straight incision. It slants from the posterior superior iliac spine to the upper margin of the greater trochanter. After detaching the tendons and pushing the muscle fibers apart, the head of the femur is dislocated and sawed off and the upper two thirds of the incision are sutured, the lower third drained. So far the operation has been simple. The whole is complete in less than twenty minutes. Then at once, or five or six days later, the limb is amputated. Hemorrhage is warded off by the assistant's fingers pressing on the vessels. This is a simple matter, as there is no bone left in the region. The whole amputation, being only in soft parts, takes but a few minutes—not over fifteen at most. There is no operative shock, no hemorrhage, and scarcely any crushing of the tissues. With this technic, he declares, disarticulation of the hip joint becomes practically a minor operation.

93 *Atypical Forms of Pneumonia in Young Children. J. P. Garrahan.—p. 168. Commenced in No. 12, p. 148.

93. **Atypical Pneumonia in Young Children.**—Garrahan mentions that in the recent unusual prevalence of pneumonia at Buenos Aires, a remarkable proportion of cases were encountered in infants less than a year old. There were three deaths, but extraneous causes could be incriminated for them. Roentgen examination has led to great progress in the management of pneumonia in young children. He found the right apex the site of the pneumonia in seventeen of his forty-one cases. In a number the onset of fever was accompanied by abdominal pains; in others, a pleural effusion dominated the scene. In one child of 2, in the third month of whooping cough, the pneumonia was accompanied with a comatose condition, with icy extremities. For four days this alarming syndrome was combated with mustard baths, oxygen, camphor, serum, epinephrin, etc. The pneumonia of the right apex was associated with an intense reaction on the part of the pleura, and the disease lasted seventeen days, but complete recovery then was prompt. The particulars of sixteen cases are given and the literature reviewed.

Semana Medica, Buenos Aires

95. **Delivery with Contracted Pelvis.**—Gabastou discriminates between primiparas and multiparas in the infected cases of contracted pelvis. Pubiotomy, which might serve well for the latter, is contraindicated for primiparas, other conditions being equal. It is also contraindicated in case of varices on the genitals. With established and grave infection, extraperitoneal cesarean section is, of course, out of the question. The Porro operation is preferable when the fetus is viable.

101 *Digestibility of Bran Bread. M. Hindhede.—p. 1047.
102 *Reinfection with Syphilis. W. J. Bais.—p. 1052.

99. **Superficial Tension as Factor in Ferment Action.**—Groll writes from the physiology laboratory of the University of Amsterdam to relate much experimental and clinical research on biochemical topics. He discusses in particular the influence on solutions of the superficial tension of various substances and ferments. All the evidence testifies to the great importance of the superficial tension and the viscosity of the medium in modifying the action of ferments and the catalytic processes.

100. **Suppurating Process in the Knee.**—Van Vliet remarks that Opitz as late as April, 1915, advocated amputation at the first signs of suppuration in the knee. Hansing two months later reported eight deaths and nine amputations in twenty-three cases of the kind. The change for the better in the outcome of such cases is shown by Heddaeus' report, in Bruns' *Beiträge*, January, 1917, that he lost only one of seventy patients with suppurating arthritis in the knee and that sixty-three were left with a fairly functionating joint. He got the cases within a day or two after the injury, and after cleaning out the wound he rinsed with 3 per cent. phenol or neutral solution of chlorinated soda, and immobilized.

Later than the second day, no treatment can save the joint. Van Vliet in his work at the Mannheim and Heidelberg hospitals did not get the cases until they were a week or two old. Even at this late stage he obtained excellent results with limited resection and fixation on a wooden frame that held the knee partially flexed, a small gap in the frame directly under the knee allowing for free drainage and open treatment of the wound. The best results were obtained when the patella and the joint cartilages were removed. This ensures better draining and better consolidation later. Open treatment of the wound saves the patient much pain and discomfort, besides the economy in dressings.

101. **Digestibility of Whole Grain Bread.**—Hindhede reiterates that the normal persons whom he subjected to his extensive tests (mentioned recently in these columns) digested bran as well as a pig digests it and, when ground fine, they digested it even more completely than cattle digest it. Von Noorden has also become convinced by experiences during the war that whole grain flour is digestible. He is now even inclined to credit to the extensive use of bran-containing bread a large part of the success attained by the so-called drugless healers. Hindhede pleads therefore that bran should not be taken from people and fed to cattle under the present circumstances. By feeding grains to animals we get back in the form of food only about 20 per cent. of the value.

102. **Reinfection with Syphilis.**—Bais writes from Sumatra to tell of a case of recent primary syphilis treated with such success, the Wassermann reaction veering to normal, that the man returned a year later with a second unmistakable primary infection. This also was conquered within a few months, the same as before. The Wassermann reaction was still negative when reexamined nine months after this second infection. The tenth month he returned with his third primary infection. The spirochetes swarmed in the primary chancre each time. Neosalvarsan and mercury had been the treatment. In a second case of reinfection there was evidence that the man contracted the infection the second time from a woman he had himself infected at his first attack, thus the same strain of spirochetes was presumably responsible for both. Bais thinks that the publication of such cases of positive cure will lessen the tendency to neurasthenia in those acquiring the disease.

TRANSFUSION OF UNMODIFIED BLOOD

AN ANALYSIS OF ONE HUNDRED AND SIXTY-FIVE CASES

LESTER J. UNGER, M.A., M.D.
NEW YORK

The results of 165 transfusions performed by means of the simple technic[1] I described in 1915 have been so encouraging as to warrant a report. This paper will present (1) an analysis of the effects of transfusion on various clinical conditions; (2) a comparison between the use of unmodified and modified blood, and (3) a summary of the results of all the transfusions.

INDICATIONS FOR TRANSFUSION

The indications for transfusion are (1) hemorrhage; (2) diseases of the blood; (3) toxemias; (4) infections; (5) shock, and (6) general debility.

1. *Hemorrhage.*—This is one of the conditions in which blood transfusion is the ideal form of treatment. It serves not only to replace lost blood but also to check actual bleeding. In acute hemorrhages, the results are naturally more brilliant than in less fulminating bleeding.

The diseases in which hemorrhage served as the indication for the transfusion of blood fall into the following nine groups: (*a*) gastric or duodenal ulcer; (*b*) typhoid fever; (*c*) postoperative hemorrhage; (*d*) ectopic gestation; (*e*) uterine hemorrhage; (*f*) ulcerative colitis; (*g*) jaundice; (*h*) hemorrhages associated with blood diseases, and (*i*) miscellaneous cases.

(*a*) Gastric or Duodenal Ulcer: There were seven transfusions done in five cases of gastric or duodenal ulcer. The supposition that, owing to the rise in blood pressure following a transfusion, the bleeding in gastric ulcer will be increased seems to have no basis in point of fact.

All of the patients were in an extremely critical condition. One transfusion was sufficient to check the hemorrhage in four of the five patients, even though they were bleeding at the time the transfusion was performed. Three of the patients made a prompt and striking recovery. They were converted within a comparatively short time from moribund individuals to convalescents. Plans for operation were abandoned because of their return to perfect health. Two of the five patients died. Each received two transfusions. In one the first transfusion checked the hemorrhage and improved his condition to such an extent that an operation with a preliminary transfusion was resorted to. The other patient was given two transfusions, neither of which succeeded in checking the hemorrhage. This was the only true failure in this group of cases.

(*b*) Typhoid Fever: Three transfusions were performed in two cases of typhoid fever because of complicating intestinal hemorrhage. In one of these, a patient of Dr. Evan M. Evans, transfusion of 1,200 c.c. checked the hemorrhage. During a subsequent relapse there was no recurrence of the bleeding, and the patient made a complete recovery. The other patient was on Dr. Libman's service at Mount Sinai Hospital. Although prompt improvement followed the introduction of 800 c.c. of blood, within a few hours she had another profuse hemorrhage. One thousand c.c. of blood were then given, but subsequent profuse hemorrhage proved fatal.

(*c*) Postoperative Hemorrhage: There were four cases of this kind. The hemorrhages followed gastro-enterostomy, cystoscopy and operations for cholecystitis and for osteomyelitis. All the patients were in a very critical condition, but following the introduction of the new blood they promptly made an uneventful recovery. The result in the patient in whom the bleeding followed gastro-enterostomy was very striking. Besides an immediate cessation of bleeding, the wild and increasing delirium entirely disappeared. Abnormal mental states varying from mild delusions to delirium frequently disappear in this way. These mental symptoms are due to anemia, and vanish when the hemoglobin and the number of red cells is increased.

(*d*) Ectopic Gestation: The three patients in this group were so desperately ill that immediate operation was deemed contraindicated. Transfusions changed the condition of all three so that surgical intervention was warranted. The lives of these three women were saved by the preliminary transfusions.

(*e*) Uterine Hemorrhage: Four transfusions were carried out in three cases of uterine hemorrhage. All the patients recovered. Two were saved from impending death. The transfusions were performed before the operation in order to replace the large quantity of blood lost. Two were instances of retained secundines and the third one of chorio-epithelioma. Two transfusions followed by a hysterectomy (by Dr. L. Druskin) were performed on the last patient referred to. She then made an uninterrupted recovery.

(*f*) Ulcerative Colitis: Three patients on whom six transfusions were performed had ulcerative colitis. All were greatly improved not only as regards their blood but in strength and appetite as well. In two the local condition at once began to respond to treatment. The third, in spite of three transfusions with attendant improvement in the general condition, obstinately resisted all local treatment. Transfusion for ulcerative colitis is of benefit, by increasing the patient's vitality and by rendering the local condition in the intestine more responsive to treatment. Repeated transfusions are usually necessary in this disease.

---

[1] Unger, L. J.: A New Method of Syringe Transfusion, The Journal A. M. A., Feb. 13, 1915, p. 582; Recent Simplifications of the Syringe Method of Transfusion, Sept. 18, 1915, p. 1029.

(*g*) Jaundice: Unfortunately this series does not include this condition. Transfusion should, however, be employed in cases of jaundice both to check active bleeding and as a prophylactic measure previous to operation when the coagulation time is considerably prolonged.

(*h*) Hemorrhage Associated with Blood Diseases: These cases are fully discussed under the general heading of diseases of the blood. In twenty-three the transfusions were given to check hemorrhage accompanying blood diseases. In eighteen it succeeded, while in five it failed. Four of these failures were in purpura hemorrhagica, and one in a case of melena neonatorum in which the patient was moribund. In four cases of leukemia, not included in the foregoing number, the bleeding was incidental, and transfusion was given not to check hemorrhage but for the underlying blood condition.

(*i*) Miscellaneous Cases: This group includes four cases and eleven transfusions. One patient had hematemeses of unknown origin. Neither an operation nor a subsequent necropsy cleared up the diagnosis. Two had intestinal hemorrhage of unknown etiology. The fourth bled from multiple hereditary telangiectases. Some of these transfusions were life saving in character. In all, bleeding ultimately recurred, and repeated transfusions were necessary.

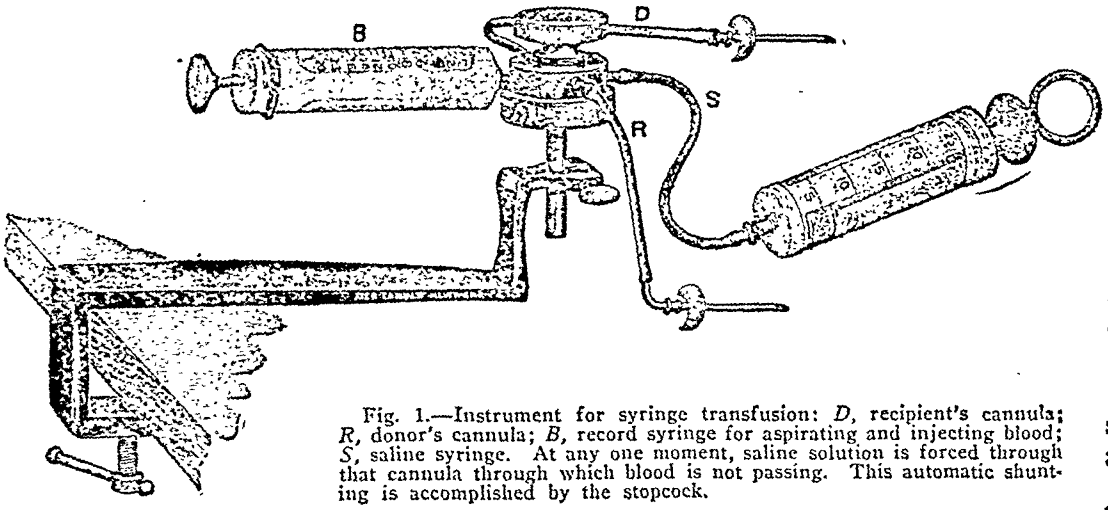

Fig. 1.—Instrument for syringe transfusion: *D*, recipient's cannula; *R*, donor's cannula; *B*, record syringe for aspirating and injecting blood; *S*, saline syringe. At any one moment, saline solution is forced through that cannula through which blood is not passing. This automatic shunting is accomplished by the stopcock.

Summary: Sixty-two transfusions were done in forty-seven cases of hemorrhage. Twenty-four patients had acute or chronic hemorrhage. Nineteen, or 79 per cent., of these, recovered — twelve because of transfusion alone, seven as a result of transfusion and operation. In the latter cases the surgeon was unwilling to attempt any operative measures without a preliminary transfusion. In fifteen, or 62 per cent., the transfusion was a life-saving procedure.

Eighteen of the twenty-three patients with hemorrhage associated with blood diseases recovered. In fifteen, or 65 per cent., transfusion was a life-saving measure.

2. *Diseases of the Blood.*—The clinical conditions were: (*a*) secondary anemia; (*b*) pernicious anemia; (*c*) hemophilia; (*d*) purpura hemorrhagica; (*e*) leukemia; (*f*) bleeding of the new-born, and (*g*) miscellaneous (Banti's disease, von Jaksch's anemia and Henoch's purpura).

(*a*) Secondary Anemia: In one patient the anemia followed malaria; in another (an infant) it was associated with malnutrition. Both patients responded promptly, and made a perfect recovery.

(*b*) Pernicious Anemia: Twenty-three transfusions were performed in fifteen cases of pernicious anemia. The lives of five were saved as a direct result of the transfusions; five patients were greatly improved; the remaining five died within a comparatively short time. Some of these cases could not be followed sufficiently long to pass judgment on the length of time for which the patients were benefited. As a result of repeated transfusion, two have done well for a period of about two years, and another for a period of eight months. A fourth died after a remission lasting six months.

The results of transfusion in pernicious anemia are superior to those achieved by any other mode of therapy. Frequently it acts as a life-saving measure by initiating the onset of a remission. There is no evidence, however, to show that the disease can be permanently cured in this way. Nevertheless, by repeated transfusions, remissions can be effected and the lives of some patients made useful for years. In such cases, if possible, the same donor should successively be employed. The amount of blood does not seem to be the determining cause of a remission. Small amounts have as often been of value as large amounts. When transfusion is successful, the marked increase in strength and appetite is very striking. It will relieve the anemia and the symptoms secondary to it—dyspnea, palpitation, mental symptoms, etc. In no instance did it lead to the secretion of hydrochloric acid by the stomach.

If transfusion is repeated because the first one failed to bring on a remission, different donors should be employed until, if possible, the desired effect is achieved. In such cases, subsequent transfusion should be resorted to, however, before all that has been gained by the previous one has been lost. In certain cases, even this procedure is of no avail.

(*c*) Hemophilia: Eight transfusions were performed in seven cases of hemophilia. All the patients recovered. Five transfusions were life-saving measures. The bleeding was controlled by one transfusion in all but one case. This child, who was bleeding from a lacerated wound of the tongue, received an unmodified blood transfusion which controlled the hemorrhage for four days. A transfusion of citrated blood was then given, but did not control the bleeding. Within a week, two whole blood transfusions were performed, and these checked the hemorrhage. Two of our patients returned months later because of fresh hemorrhages.

Transfusion does not permanently cure the disease hemophilia. It is, however, practically a specific for the bleeding of hemophilia. It will succeed when other measures fail. Five of the patients were treated unsuccessfully with thromboplastin (Squibb), coagulen (Ciba), epinephrin, astringent solutions, citrated blood, subcutaneous injections of whole blood, and iodoform gauze packing. In four of the cases thus treated, bleeding was stopped by one unmodified blood transfusion, while in one case two transfusions were required. In this connection it must, however, be remembered that transfusion is resorted to only in cases in which other measures have failed. Valuable time should not be wasted in attempts to control bleeding by these methods when we have at our command a specific that will not only control the hemorrhage but also replace the lost blood. The danger of delay is illustrated by the following case:

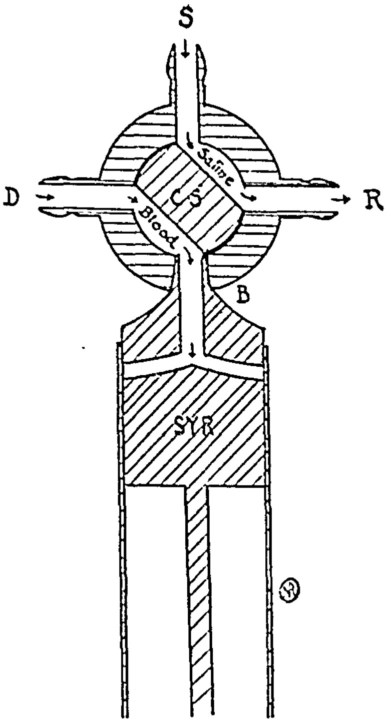

Fig. 2.—Donor's position: *D*, donor's outlet; *B*, blood outlet; *SYR*, blood syringe. Blood passes from donor's vein through *D*, and out at *B* into *SYR*. *S*, saline outlet; *R*, recipient's outlet. Saline solution is forced from saline syringe through *S*, out at *R*, into recipient's vein. *C S*, central stopper (rotates through an arc of 90 degrees).

A child, aged 4 years, was known from his family history to be a hemophiliac. For a period of eleven days prior to being admitted to Dr. Koplik's service at Mount Sinai Hospital, packing with various astringent solutions and also coagulen were used to check bleeding from the nose. By this time the hemoglobin was 25 per cent., and the patient was in such a desperate condition that death seemed imminent. A transfusion of 400 c.c. of whole blood immediately checked the hemorrhage, and raised the hemoglobin to 50 per cent. Eight months later when his nose again began to bleed, it was immediately packed with gauze soaked in thromboplastin and a transfusion at once performed. The hemorrhage was controlled before there was any great loss of blood.

(*d*) Purpura Hemorrhagica: Purpura hemorrhagica is a condition that one would expect to be favorably influenced by blood transfusion. The results of the six cases in this series were not, however, as good as we should hope for. In two of the cases the bleeding was controlled, in one it was not at all affected (epistaxis), and in three death ensued.

In the three fatal cases, the patients were in extremely poor condition and had the severest manifestations of purpura. All three had numerous petechiae, purpuric spots, hematomas and active bleeding, such as from the gums, nose, kidney and vagina. They all showed typical findings of purpura hemorrhagica—a secondary anemia, diminished blood platelet count, positive capillary resistance test, normal coagulation time, prolonged bleeding time, and positive puncture test. In one case the bleeding time was more than an hour; at this point the test was discontinued and the bleeding had to be controlled by pressure.

The paradoxical finding in purpura of a diminished platelet count with a normal coagulation time has recently been shown by Dr. Alfred F. Hess to be only apparent.[2] As a matter of fact, purpuric blood actually has a normal amount of blood platelet material. This material exists in two forms — the visible platelets, and platelets that are in solution in the plasma. He believes that purpura hemorrhagica is caused by a toxin which not only dissolves blood platelets but may also injure the blood vessel walls, bringing about the other manifestations of the disease. Since in certain hemolytic diseases the toxin is thought to be associated with the spleen, he has suggested that in purpura, after preliminary transfusion, splenectomy be performed. This suggestion gains added force when we remember that following splenectomy there is an increase in blood platelets. In view of the marked fatality of some forms of this disease and the rather discouraging result from transfusion alone, or any other form of therapy in this type, this suggestion ought to be given a trial.

(*e*) Leukemia: In six cases of acute lymphatic leukemia, thirteen transfusions were performed. Three cases were practically counterparts of one another, and occurred in adults. These patients were bleeding from a mucous membrane, and had petechial and purpuric spots, fever, marked secondary anemia, a typical leukemic white count, and negative blood cultures. One had enlarged glands, and two an enlarged spleen. The transfusions in all these cases raised the hemoglobin; increased the number of red blood cells; diminished the number of white cells, leaving the differential count practically unchanged; lowered the temperature; improved the general condition, and stopped the hemorrhages. But in all three, relapse soon occurred, bleeding recommenced, and the result was fatal.

One of these patients, who came from Dr. Alfred Meyer's service at Mount Sinai Hospital, was given a "substitutive transfusion." A phlebotomy of 500 c.c. was immediately followed by a transfusion of 1,000 c.c. A second phlebotomy of 600 c.c. was followed by a second transfusion of 1,000 c.c. from another donor. The benefit lasted for six days, when he became rapidly worse and died.

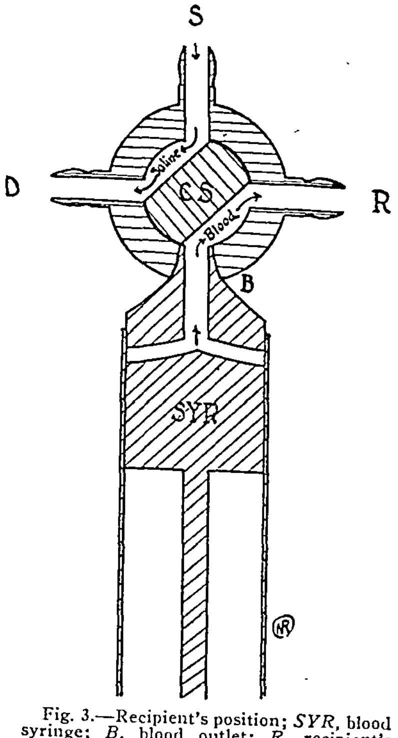

Fig. 3.—Recipient's position; *SYR*, blood syringe; *B*, blood outlet; *R*, recipient's outlet. Blood is forced out of *SYR* through *B*, out at *R*, into recipient's vein. *S*, saline outlet; *D*, donor's outlet. Saline solution is forced from saline syringe through *S* out at *D* into donor's vein. *C S*, central stopper.

The other three cases were in children with subleukemic leukemia. These patients had fever, a profound anemia with a normal or diminished total number of leukocytes, but a high percentage of lymphocytes. In one patient an attempt was made to influence the course of the disease by repeated transfusions. After each of eight transfusions, his general condition and anemia were improved. Soon, however, it became evident that no permanent impression on the disease was being made, but that it was merely being prolonged. I wish to emphasize the fact that one other patient was seen early in the disease, before the diagnosis of leukemia was made. The transfusions were given to overcome marked anemia. Although repeated transfusions sustained the hemoglobin, the white count became typical of leukemia. It is evident, therefore, that in acute lymphatic leukemia only a temporarily favorable effect can be secured by transfusion, even though we withdraw a large amount of blood by phlebotomy and make use of a massive transfusion from two donors, or employ repeated transfusions, in spite of carrying out such transfusions very early in the disease.

---

TABLE 1.—RESULTS OF TRANSFUSION FOR HEMORRHAGE

Indication	Number of Transfusions	Number of Cases	Recoveries (Hemorrhage Checked)		Deaths	
			Prognosis Bad; Life Saved	Prognosis Not Bad	Temporary Improvement	No Improvement
Gastric ulcer	7	5	3	0	1	1
Typhoid fever	3	2	1	0	0	1
Postoperative hemorrhage	4	4	4	0	0	0
Ulcerative colitis	6	3	0	3	0	0
Hemorrhage with blood diseases	24	23	15	3	2	3*
Ectopic gestation	3	3	3	0	0	0
Uterine hemorrhage	4	3	2	1	0	0
Miscellaneous cases	11	4	2	0	1	1
	62	47	30	7	4	6

* One of these patients is still alive, but the transfusion did not entirely check the hemorrhage.

(*f*) Bleeding of the New-Born: In nine of the ten cases of this kind of bleeding, transfusion proved a life-saving measure. The one patient who died was moribund when the transfusion was started. In bleeding of the new-born, transfusion is a specific. An almost exsanguinated infant, too weak to cry and in a dying state, is immediately transformed into an apparently healthy, rosy and crying baby. As in hemophilia, it will save the lives of those who are not helped by subcutaneous injections of serum or blood. Temporizing by using less effective measures may cost the baby's life. This is especially true in cases of melena neonatorum, which are the most serious because we do not know just when the hemorrhage began or how much internal hemorrhage is taking place. Just as soon as the diagnosis of bleeding from the stomach or bowel of the new-born is made, transfusion should be performed. In cases of melena it is well to remember that because of the blood in the intestine, the stools may be tarry for one or two days after the transfusion, although the hemorrhage has stopped.

In one case the bleeding followed circumcision, and another patient bled from the cord. Eight bled from the bowel in addition to other hemorrhages from such sources as the stomach, kidney, vagina, hard palate or skin. The ages of the patients with melena varied from 32 hours to 6 days. The amount transfused varied from 80 to 150 c.c. No untoward reaction followed any of these transfusions. In every case the median basilic vein was used for the introduction of the blood. An incision from one-fourth to three-eighths inch long directly over the vein is sufficient even in the youngest child. The superior longitudinal sinus was not selected because of possible dangers associated with its use, and because the median basilic vein affords a comparatively simple approach. If the inferior wall of the superior longitudinal sinus is accidentally perforated, there is real danger of injecting blood on the brain or of active hemorrhage occurring, especially as these patients have a hemorrhagic tendency. Using this route for aspirating blood for examination (syphilis, bacteremia) is quite another matter, particularly in nonhemorrhagic cases.

(*g*) Miscellaneous Cases: There were four cases of Banti's disease. All of these patients died. There was one patient with von Jaksch's anemia who was greatly improved after the transfusion, but whose ultimate welfare could be not be followed, and one with Henoch's purpura, whose symptoms were relieved by transfusion.

Summary: In pernicious anemia, transfusion is of value and to be recommended, but can be expected to produce remissions in only about half of the cases. In hemophilia it can be relied on to stop the hemorrhage, but in no way to affect the course of the disease. In purpura it is much less reliable; in fact, recovery followed in only two of our six patients. In acute leukemia it is of but temporary benefit. In bleeding of the new-born it is a specific and essentially a life-saving measure.

3. *Toxemia.*—Transfusions have long been employed in a limited number of types of toxemia. It is in this group that we ought to enlarge the indications, especially in toxemias associated with acute infections, such as pneumonia and typhoid fever. A remarkable and unexpected result of transfusion in a case of toxemia of pregnancy ought to be followed by further attempts at combating this disease in this way. Transfusions were done for toxemias associated with: (*a*) pneumonia; (*b*) pyogenic infections; (*c*) coal gas poisoning; (*d*) morphin poisoning; (*e*) uremia; (*f*) scurvy, and (*g*) toxemia of pregnancy.

(*a*) Pneumonia: Four children with bronchopneumonia were transfused because of extreme toxemia. They were all in very poor condition at the time, but responded favorably and progressed to recovery.

TABLE 2.—RESULTS OF TRANSFUSION FOR BLOOD DISEASES

Indication	Number of Transfusions	Number *of* Cases	Recoveries		Deaths	
			Bad Prog*nosis;* Life Saved	Prognosis Not Bad	Temporary Improvement	No Improvement
Secondary *anemia*	2	2	1	1	0	0
Pernicious anemia	23	15	5	5	4	1
Hemophilia	8	7	5	2	0	0
Purpura hemorrhagica	6	6	1	1	2	2
Leukemia	13	6	0	1	5	0
Bleeding of new-born	10	10	9	0	0	1
Miscellaneous	6	6	0	2	4	0
Total	68	52	21	12	15	4

(*b*) Pyogenic Infections with Extreme Toxemia: There were four patients: two had empyema pleurae, one had salpingitis and peritonitis, and one a subphrenic abscess. All were extremely toxic and died following temporary improvement.

(*c*) Coal Gas Poisoning: In the sole case of coal gas poisoning in this series, the patient had beginning pulmonary edema, and was moribund when seen. In fact, in order to keep him alive until transfusion could be performed, artificial respiration was employed. Although transfusion was preceded by phlebotomy, the result was fatal.

(*d*) Morphin Poisoning: Although no case of this type was treated, it is interesting to note that the effects of morphin given previous to some of the transfusions seemed to be lessened immediately thereafter.

(*e*) Uremia: All three patients with uremia were in a hopeless condition. Transfusion was followed by a transitory improvement in the course of the disease. Although this series includes no transfusions for diabetic coma, the results of others have been unsatisfactory.

(*f*) Scurvy: Although many consider this condition a deficiency disease, others believe it is due to a toxin, and therefore it has been included in this group. The one patient had subacute scurvy. Improvement was immediate and marked. A pulse of 180 and respiration of 60 (cardiorespiratory syndrome of Hess) were changed to 120 and 40, respectively. The inability to gain in weight that is characteristic of scurvy was overcome.

(*g*) Toxemia of Pregnancy: The one case of this type, a patient of Dr. Rongy, was deeply jaundiced, comatose and moribund. The toxemia was hepatic in origin. Transfusion was preceded by phlebotomy. The coma soon disappeared, but in spite of the fact that for a time the outcome seemed dubious, she made a complete recovery.

4. *Infections.*—These cases may be divided into two groups: (*a*) localized pyogenic infections, and (*b*) bacteremia.

(*a*) Localized Pyogenic Infections: In an effort to increase the patients' vitality and to overcome the infection, five patients with intractable suppurative processes were transfused. Three were greatly improved and went on to recovery. They suffered from pelvic abscess, multiple abscesses of the kidney, and pyarthrosis. All were also given surgical treatment. Two patients died, one of gas bacillus infection of the leg and one of pylephlebitis. After each of the five transfusions given the latter patient, there was a period of temporary improvement.

(*b*) Bacteremia: Eleven transfusions were given ten patients with bacteremia. There were two cases of infective endocarditis, one of bacteremia following cholecystectomy, and seven of puerperal sepsis. In all there was an improvement of the general condition, and in some a cessation, for a short period, of the chills. The temporary benefit was followed by death. Perhaps, however, the bacteremia could be combated in some instances if immune donors were used in an attempt to establish a passive immunity.

5. *Shock.*—Transfusions were performed in three cases because of shock. Two were postoperative and one traumatic in origin.

One of these patients had been run over by a heavy automobile truck, sustaining a compound fracture of the humerus. As there was a possibility of internal hemorrhage from a ruptured spleen, transfusion and exploratory laparotomy were performed. It was then evident that the signs were those of profound shock and not hemorrhage. The patient made a complete and remarkable recovery. The second patient was transfused immediately after a splenectomy (Dr. Howard Lilienthal), and recovered. In the third case, shock was also postoperative in origin. Here, however, various drugs as well as an intravenous infusion of saline solution were employed before transfusion was resorted to. After a brief rally, the patient died.

It is interesting to note that the two patients who recovered were transfused almost immediately after shock became evident. It is possible that the time element is a deciding factor.

6. *General Debility.*—Transfusion as a supporting measure was employed (*a*) preliminary to operations, and (*b*) in debilitating diseases.

(*a*) Preliminary to Operations: There were six patients with carcinoma with such a severe grade of anemia that they were considered poor operative risks. Five had carcinoma of the stomach, and one carcinoma of the head of the pancreas. Four survived the operations, and two died. There is no doubt that transfusion lessened the postoperative mortality.

(*b*) Debilitating Conditions: The patients included in the preceding group suffered from debilitating diseases, but since they were in fair condition, operation was permissible. There were, however, fourteen other similar patients. Six had carcinoma, but were in such desperate straits that operation could not be thought of. They were transfused merely to improve their general condition and prolong their lives. Five were transfused as measures of last resort. All were moribund. The diagnoses were ulcerative colitis, syphilitic stricture of the jejunum, acute insufficiency of the liver, and pemphigus (two cases). Patients with interstitial nephritis, acute parenchymatous nephritis, and cirrhosis of the liver were improved by the transfusion, and were able to leave the hospital.

TECHNIC

All of the 165 transfusions were performed by the method previously reported.[1] This method utilizes the instrument described in the accompanying illustrations. The mechanical principle involved is the establishment of two channels by means of which a record syringe is automatically connected alternately with a vein of the donor and then with one of the recipient. At the same time that the record syringe is connected with the donor for the aspiration of blood, a syringe with saline solution is connected with the recipient, and vice versa. It is this immediate and continued flushing with salt solution of the channel through which blood is *not* passing that insures freedom from clotting.

The technic is as follows: Alongside the instrument, which has been fixed to a table, the arms of the patient and the donor are placed. The tubes leading from the instrument are connected to the cannulas after the latter have been inserted through the skin into the recipient's and the donor's veins. A record syringe is then inserted into the instrument, and blood is aspirated. When the syringe is filled, the stopcock is turned and the blood is injected. A continuous stream of saline solution is forced in a direction opposite to the flow of blood. This procedure is continued until the desired amount is transfused. By means of a spray, a stream of ether is played on the barrel of the record syringe while it is being filled with and emptied of blood in order to prevent clotting. In this way only one record syringe is required, regardless of the amount transfused.

COMPARISON BETWEEN THE USE OF UNMODIFIED AND MODIFIED BLOOD

One of the points of active interest in connection with transfusion is that of the relative merits of unmodified blood and of blood that has been modified by means of small amounts of sodium citrate. As is well known, the latter method has recently gained considerable vogue, and, indeed, by some is claimed to render other methods of transfusion unnecessary. This is the view that has been recently stated by Bernheim.[3] From my point of view, transfusion of unmodified blood cannot be so lightly set aside. It has been shown recently by Novy[4] and DeKruif that blood acquires toxic properties in direct proportion to the path it travels toward coagulation. Even though it does not absolutely coagulate, processes take place within it, as soon as it is poured forth from the vessels, that change its nature and render it less suitable as a body fluid. These studies are new and as yet incompletely worked out. They seem to show, however, what *a priori* would seem to be most likely, that from a biologic point of view such a delicate tissue must be altered in the carrying out of a transfusion of citrated blood[5] because of its considerable sojourn outside the body. From a clinical standpoint, this alteration is also evidenced. Frequently chill and fever and occasionally vomiting follows transfusion of citrated blood, while whole blood is only occasionally followed by fever, and a chill is the exception.[6] I believe that for diseases in which blood is indicated for itself, that is, when it is required as a tissue, as in the various anemias, there can be no question as to the relative merits of unmodified blood which runs almost from vessel to vessel and of that which has remained for an indefinite length of time outside of the body. The transfusion of unmodified blood is the procedure of choice. It must be admitted, however, that the technic for giving citrated blood is simple, and that therefore in cases of hemorrhage, in which the purpose is not so much to supply normal for pathologic blood as to furnish the impoverished circulation with an adequate supply or to bring about cessation of hemorrhage, citrated blood may serve as a substitute.

SUMMARY OF RESULTS

In all, 165 transfusions were performed on 128 patients. These can be classified according to results as either recoveries or deaths.

1. *Recoveries.*—Seventy-one, or 55 per cent., of the patients recovered. They either had very bad prognoses and their lives were saved, or they had better prognoses and were definitely helped. The lives of forty-four, or 34 per cent., were saved by the transfusion. The vast majority of these had hemorrhages or diseases of the blood.

(*a*) Cases in Which Life Was Saved:[7] Bleeding gastric or duodenal ulcer, 3; intestinal hemorrhage in typhoid fever, 1; postoperative hemorrhage, 4; ectopic gestation, 3; uterine hemorrhage, 2; intestinal hemorrhage of unknown origin, 2; profound secondary anemia following malaria, 1; pernicious anemia, 5; hemophilia, 5; purpura hemorrhagica, 1; bleeding of the new-born, 9; toxemia in pneumonia, 4; scurvy, 1; toxemia of pregnancy, 1; shock, 2.

(*b*) Cases in Which There Was Definite Benefit, but in Which the Transfusion Was Not a Life Saving Procedure: Ulcerative colitis, 3; uterine hemorrhage, 1; profound secondary anemia, 1; pernicious anemia, 5; hemophilia, 2; purpura hemorrhagica, 2; acute lymphatic leukemia, 1; von Jaksch's anemia, 1; Henoch's purpura, 1; profound anemia secondary to chronic suppuration, 3; carcinoma of stomach, 4; acute parenchymatous nephritis, 1; chronic interstitial nephritis, 1; hepatic cirrhosis, 1.

2. *Deaths.*—In eight patients there was no improvement, although from the nature of the disease a good result might have been expected. The deaths of the others were due to the underlying disease. Some were in such a condition that although little was expected of the transfusion, it was done as a measure of last resort. In the others, death was preceded by temporary improvement.

(*a*) Cases in Which a Good Result Might Have Been Expected: Bleeding gastric ulcer, 1; intestinal hemorrhage from typhoid fever, 1; hemorrhage from multiple hereditary telangiectases, 1; pernicious anemia, 1; purpura hemorrhagica, 2; bleeding of the new-born, 1; shock, 1.

(*b*) Cases in Which Death Was Due to the Underlying Disease: Gastric ulcer (the patient died following an extensive operation), 1; hematemeses of unknown etiology, 1; pernicious anemia, 4; purpura hemorrhagica, 1; acute leukemia, 5; Banti's disease, 4; empyema of the thorax, 2; acute salpingitis, 1; subphrenic abscess, 1; uremia, 3; coal gas poisoning, 1; pylephlebitis, 1; gas bacillus infection, 1; infective endocarditis, 2; bacteremia following cholecystectomy, 1; puerperal sepsis, 7; carcinoma of stomach, 5; carcinoma of colon, 2; carcinoma of the head of the pancreas, 1; ulcerative colitis, 1; pemphigus, 2; syphilitic stricture of the jejunum, 1; acute hepatic insufficiency, 1.

TABLE 3.—SUMMARY OF RESULTS OF TRANSFUSION

Indication	Number of Transfusions	Number of Cases	Recoveries		Deaths	
			Bad Prognosis; Life Saved	Prognosis Not Bad	Temporary Improvement	No Improvement
Hemorrhage	38	24	15	4	2	3
Blood diseases	68	52	21	12	15	4*
Toxemias	14	14	6	0	8	0
Infections	20	15	0	3	12	0
Shock	3	3	2	0	0	1
General debility	22	20	0	7	13	0
Total	165	128	44	26	50	8

* Although one of these patients did not die, the case is grouped here because little improvement followed transfusion.

CONCLUSIONS

1. The best results of transfusion were obtained in hemorrhage, diseases of the blood, toxemias and shock. In 88 per cent. of the cases of acute hemorrhage, bleeding was stopped by one transfusion. In pernicious anemia, remissions can be initiated. Repeated transfusions frequently bring on repeated remissions. If no remission results, transfusion with a different donor should be performed. For the hemorrhage of hemophilia, transfusion is practically a specific. It is dangerous to delay too long with palliative measures if active bleeding is present. In purpura, transfusion gives only moderately good results. In the severe cases, it would seem advisable to carry out the suggestion of splenectomy with preliminary transfusions. All attempts to influence acute leukemia failed. In bleeding of the new-born, transfusion is a specific. Especially in cases of melena, temporizing by using other methods is contraindicated. The median basilic vein can be used regardless of the baby's age, and is the route of choice.

[6] Of all the patients in this series, eleven had febrile reactions and two had chills. In two other cases, reactions were anaphylactic in nature, while in still another in which tests had been omitted it was due to hemolysis. Reference may also be made to Libman and Ottenberg: Am. Jour. Med. Sc., 1915, **150**, 36.

[7] The figures refer to the number of patients treated by transfusion.

Transfusion, although employed in a comparatively small number of cases, has yielded encouraging results in toxemia associated with acute infections (e. g., pneumonia), toxemia of pregnancy, scurvy and shock. It seems to overcome shock if employed at the onset of the symptoms.

2. Transfusion is often of assistance in overcoming intractable suppurative processes and causing a marked increase in the vitality of the patient. In bacteremias, it has had practically no success. It is possible, however, that if immune donors were used the results might be better. Transfusion given preliminary to an operation will often so improve the patient's condition that the surgeon is justified in risking an operation. It will prolong the life of a patient suffering with a debilitating condition.

3. The syringe cannula method (requiring only one syringe) has proved a simple, efficient and dependable one for giving whole unmodified blood. The giving of unmodified blood is the method of choice when blood is required as a tissue (as in various anemias). When it is required to replenish impoverished circulation, citrated blood can serve as a substitute.

162 West Eighty-Fifth Street.

THE BIOLOGIC CLASSIFICATION IN PNEUMOCOCCIC INFECTIONS *

C. C. HARTMAN, M.D.
AND
G. R. LACY, M.D.
PITTSBURGH

This report is a summary of our results in classifying pneumococci according to their biologic differences. The material was obtained from patients admitted to the Allegheny General Hospital and from patients in Pittsburgh and its suburbs. The technic used was identical with that developed at the Rockefeller Institute and reported by Dochez and Gillespie,[1] Cole,[2] Avery[3] and others. The pneumococci were isolated from the sputum. In many instances, blood cultures were also taken and, when other conditions were present or developed later, such as meningitis, empyema, lung abscess, acute otitis media and mastoiditis, cultures were taken from them. In several necropsies in which pneumonia was encountered, cultures were taken from the lung, the heart's blood and the obvious accompanying lesions. The purpose of these various cultures was to determine whether the cultures of pneumococci from various lesions in the body corresponded in regard to their biologic classification.

Five of the patients suffering from pneumonia of Group I were treated with the corresponding antiserum. Treatment was instituted late in four cases; one of these patients recovered. Two of the patients developed a meningitis and received the antiserum both intravenously and intrathecally. Blood cultures taken twenty-four hours after the administration of the serum were positive three times in one patient and twice in the other. Cultures of the spinal fluid after the administration of the serum were also positive. The other recovery occurred in a laboratory worker accidentally infected while working with a very virulent organism of Group I. The onset was violent; and despite a rather hopeless outlook, the disease yielded in a decisive and gratifying manner to the early administration of the antiserum.

The accompanying table shows the number of patients studied (including the subjects of twelve necropsies), the incidence of the various groups of pneumococci, the mortality, etc. Those included in the group of "unclassified, streptococcus, etc." are those in whom the pneumococcus was not obtained or identified, or those in whom the culture proved to be streptococci.

INCIDENCE AND MORTALITY OF PNEUMOCOCCI

Groups	Incidence		Number of Deaths	Mortality, per Cent.	Remarks
	Number	Per Cent.			
I	41	41.4	15	36.5	5 treated with serum (3D.-2R).
II	29	29.3	10	31.5	3 *Subgroup II*
III	6	6.0	4	66.6	2 mastoid — *recovered*
IV	23	23.2	6	26.0	
Unclassified, streptococcus, etc.	13	....	3	23.0	
Total......	112				
Total without unclassified..	99	....	35	35.3	

The incidence of the various groups of pneumococci apparently agrees quite closely with that found elsewhere (Cole[2]). There is some variation in the mortality, that in Group IV being high, but it is not great enough to preclude being evened up in a larger series.

Of ten blood cultures taken from those suffering from Group I infections, nine were positive. Of six taken in Group II, two were positive. The one taken in Group III was positive, and the three taken in Group IV were negative. Out of the nine Group I patients yielding positive blood cultures, six died, a mortality of 66.6 per cent. Three were treated with antiserum, one of whom recovered. In two patients of Group II yielding positive blood cultures, one died, and in four yielding negative cultures, three died. The one Group III patient yielding a positive blood culture died. Of the three in Group IV yielding negative cultures, one died. Of the twelve patients in all groups yielding positive blood cutures, eight died, a mortality of 66.6 per cent. Of eight cultures taken from the heart's blood at necropsy, six were positive, three of them belonging to Group I and one to each of the other three groups, and two were negative, belonging to Group II.

Cultures from ten pleural effusions yielded pneumococci classified thus: Group I, four times; Group II, four times, and Group IV, twice. Only one patient, whose infection was due to an organism of Group I, died.

In ten instances of meningitis, seven belonged to Group I, two to Group II, and one to Group IV.

From twenty-one patients, including the subjects of twelve necropsies, cultures were made from two or more sources. In all instances, the cultures of pneumococci thus obtained from each patient belonged to the same group.

In the course of our studies we observed a recurrence, or second infection, in two patients. The one had as his first infection a member of Group IV, and the other a member of Group II. In their second attack both suffered from infections belonging to Group I. The one was exposed to an infection with a Group I organism, because on two occasions of several days' duration he had occupied a bed adjacent to a patient suffering from an infection belonging to Group I. As to a similar exposure of the other, we are not certain, though he was in the same ward with patients infected with the other groups of pneumococci. Both recovered from both attacks.

SUMMARY

The foregoing report shows that the incidence of the various groups of pneumococi occurs in a similar ratio to that in the pneumonias elsewhere. The mortality is fairly comparable. When blood cultures are taken, those yielding positive results are more serious, though one would probably obtain many more positive cultures if they were taken daily. It would seem that most of the instances of meningitis are due to organisms of Group I. When numerous cultures are taken from several sources in the patient, these cultures invariably belong to a single group.

A UNIFORM AND GENERALLY APPLICABLE SYSTEM FOR REPORTING SURGICAL END-RESULTS

E. MAC D. STANTON, M.D.
Fellow of the American College of Surgeons
SCHENECTADY, N. Y.

The foundation of future progress in surgery must consist largely of a comprehensive understanding of the successes and failures of the past. In view of the fact that several million operations have been performed in this country alone during recent years, we should now have abundant data about the end-results of operations frequently performed. The lack of available end-result data in many important fields of surgery is little short of amazing.

A few years ago, the medical director of one of the life insurance companies undertook to determine the insurability of persons recovering from the commoner types of surgical kidneys. Out of 100 surgeons consulted, only eight were able to furnish data of any value on the subject, and the medical director was obliged to conclude that very few surgeons could make a definite statement, based on their own work, concerning the ultimate effect of their kidney operations on the comfort and duration of life of their patients.

At the lowest estimate, between 20,000 and 30,000 operations for exophthalmic goiter have been performed in this country during the past ten years. Yet, except for some fragmentary data on the subject of the operative mortality and general trend of the end-results obtained in several clinics in which special skill has been developed in handling these cases, the surgical profession itself is in almost complete ignorance as to the actual results obtained through this large number of operations for exophthalmic goiter. During the same period, there have been several hundred thousand operations on the gallbladder and ducts; yet up to June, 1917, surgeons have had no really definite data to show the frequency of recurrences after these operations. No one knows the relative proportion of recurrences following cholecystostomy and cholecystectomy, and today the whole question of cholecystostomy versus cholecystectomy is debatable because the data to settle the question have not been collected. As a matter of fact, much of the literature of the past few years has been based on only the most meager and indefinite data. A similar lack of adequate end-result knowledge might be cited in many other fields of surgery.

Several reasons have been assigned for this lack of knowledge, such as the difficulty of keeping track of patients and the time and labor required to ascertain and record the results. My own end-result studies, carried on through a period of ten years, have convinced me that the chief reason for our present-day lack of end-result knowledge is that surgeons have not as yet devised a uniform and satisfactory system of reporting the data they have collected. Surgical literature is full of communications dealing in a general way with the subject of end-results, in which it is evident that authors possess considerable data which they despair of presenting in other than the most general terms.

Some time ago, I found that I had several thousand histories with end-result records extending over fairly adequate periods of time. But whereas these records had been collected with, let us say, one unit of energy on my part, when I came to study any one group of cases, it took several units of time and energy to put the data into form suitable for study and comparison. In some groups, it was quite impossible to classify the results according to the usual standards. Also I found that no two surgeons adopted the same standards in reporting their cases, so that it was impossible to compare small groups from different sources or to combine them into larger series, of greater statistical value.

As a rule, surgeons have attempted to state their end-results in terms such as "cured," "improved," "unimproved" or "dead." The trouble with this system is that in practice it is often quite impossible to assign a given case under any one head. As a typical example of the difficulties encountered, I will cite the following gallbladder case:

> A man, aged 45, had typical gallstone attacks for twenty-five years. A cholecystostomy was performed, Nov. 10, 1908. The ducts were free; 1,675 stones were removed from the gallbladder. Seven years after this operation, the patient told me that he had never had a symptom of his old trouble, and felt ten years younger than he did before the operation. Seven years and five months after the operation, however, he again developed gallstone colics accompanied by jaundice which increased in frequency and severity until, eight years and four months after the first operation, he was again operated on and a large stone removed from the common duct.

It is obvious that this case does not fit under the heading "cured" or, for that matter, in any other group. It is also obvious that the only way to state the end-results of the first operation in this case is to use some statistical method which will give the first operation credit for a cure extending over seven years and five months, after which there was no further benefit from this operation. Thus far, this patient's history has been traced eight years and five months, during 88 per cent. of which time he was cured by the original cholecystostomy.

Similar difficulties occur with greater or less frequency in practically all fields of surgery. In cases of exophthalmic goiter it is practically impossible to state the end-results following operations in the terms usually employed by surgeons reporting end-results. Gallbladder and kidney cases are little, if any, better, and gynecologic cases present similar difficulties. When we seek the reason for the difficulties encountered in trying to state end-results in such simple terms as "cured" and "improved," it is evident that these terms are descriptive of the relative postoperative health at a given period of time only, whereas to give a true description of the postoperative health of the patient, extending over a period of months or years, the element of time must be included in the description. It is as illogical to attempt to measure the postoperative life in terms that ignore the time factor as it would be to attempt to measure a plot of ground in terms of one dimension.

All the major difficulties of presenting the end-results disappear if we tabulate the results in terms of the periods of time for which the patients' histories have been traced after the operation, together with their state of health for the time periods. By this method, the "cured" column becomes "years cured," and the term "years" is added to the other divisions. It is also of advantage to add the headings "years operated" and "years traced," as illustrated in the accompanying table, which shows the results of tabulating 100 gallbladder cases by this method.

END-RESULTS FOLLOWING GALLBLADDER OPERATIONS

Diagnosis	Operation	Operations	Years Operated	Average Years Operated	Years Traced	Average Years Traced	Cured		Improved		Unimproved		Deaths	
							Years	Per Cent.	Years	Per Cent.	Years	Per Cent.	Years	Per Cent.
Gallstones.......	Cholecystostomy	42	190 1/12	4 6/12	121 1/12	2 9/12	87 3/12	72	23 3/12	19	7 4/12	6	3 4/12	3
Gallstones.......	Cholecystectomy	23	67 7/12	3	61 1/12	2 4/12	46 9/12	73	10 9/12	17	1 10/12	3	4 9/12	7
Cholecystitis....	Cholecystostomy	13	53 2/12	6 9/12	51	3 11/12	9 10/12	19	21 2/12	41	20	40	0	0
Cholecystitis....	Cholecystectomy	14	20 11/12	1 6/12	16 8/12	1 2/12	10 3/12	62	3 5/12	20	3	18	0	0
Common duct...	....	3	5 3/12	1 8/12	5 1/12	1 8/12	1	..	....	..	....	..	4 1/12	...
Totals........	....	100	392	3 11/12	257 11/12	2 7/12	58 6/12	60	58 6/12	22.6	32 2/12	12.4	12 2/12	5

A statistical correction should be made for the cases in which the patients die immediately after operation. As their histories are traced up to the time of death, it would be obviously unfair to give them full time in the "years dead" column. The factor for correction here is the proportion of the total postoperative time for which surgeons have been able to trace their patients. On the assumption that they have been traced 80 per cent. of the total postoperative time, a patient dying at operation five years before is given 80 per cent. of this time, or four years, in the "years dead" column.

The advantages of this system of recording end-results are quite obvious. No matter how complicated the postoperative history, it may be readily subdivided and classified into the appropriate periods. It is not necessary for the surgeon to trace each case to the time of reporting his results. If he has lost track of his patients soon after operation, this fact is clearly shown by his figures, and the value of the data may be judged accordingly. Long series of cases may be reported individually, by the use of only a line to a case, so that the postoperative histories of several hundred cases may be detailed on a page or two of a medical journal. To summarize an entire series of cases, it is only necessary to add the figures and strike the averages, and the results show at a glance the mean postoperative prognosis for the disease in question in the hands of the surgeon making the report.

The wealth of information conveyed by data summarized by this method is often surprising. For instance, a glance at the "years operated" column in the accompanying table reveals the fact that the surgeon reporting these cases did a number of cholecystostomies for noncalculous cholecystitis, but that this operation has not been popular with him in recent years. It also shows that lately he has been doing cholecystectomy in similar cases.

In conclusion, I wish to emphasize the fact that the plan for recording end-results as described in the foregoing is almost universally applicable to the summarizing of surgical end-results. If it were generally adopted by surgeons in reporting their results, then data from diverse sources would become available for the compilation of long series of cases and for the numerous comparative studies which are necessary if we are to determine the real factors making for success or failure in our work.

Illuminating Company Building.

Production of Vegetable Oils.—The war has made the production of all sorts of fats and oils highly important. Consul Charles L. Hoover at Sao Paulo, Brazil, in *Commerce Reports*, November 21, reports on the development of the vegetable oil industry in his district. Although a great deal of cotton has been raised in the state, until recently no cottonseed oil was produced, all of it used being imported from the United States. The manufacture of the oil has now begun, however, and several factories are in operation, oil of the highest quality being produced. Whereas in 1913 over 2 million pounds of oil was imported, in 1917 only two small shipments were brought in and the exports considerably exceeded the imports. Castor oil is another oil that is now being produced in that state. The castor bean grows wild and has been regarded as something of a pest, as it is hard to eradicate. Modern machinery is being bought in the United States for producing the oil in larger quantities. Linseed oil has heretofore been imported almost exclusively from England and Argentina. Preparations are now being made to produce this oil from the flaxseed, which is being extensively grown. Peanuts are also now being given attention as a source of oil. Several varieties of nuts found in the district are available for their oil. Among these are the cashew nut, the ucuba, which is said to be 60 per cent. vegetable tallow, and the babasu, which also contains 60 per cent. of oil. The babasu nut, it is said, will burn for half an hour if a match is touched to it. Its kernel is like copra, and it is excellent for soap making.

AN UNUSUAL CASE OF ACUTE MYELOGENOUS LEUKEMIA

H. THEODORE SIMON, M.D.
AND
MAURICE S. ROSENTHAL, M.D.
NEW ORLEANS

The acute types of leukemias are often difficult or impossible of diagnosis. The descriptions of clinical and postmortem findings in acute myelogenous leukemia especially are so rare in the available literature that it was thought for a while that this type did not exist as a pathologic entity. As the case in question was diagnosed definitely only at the postmortem, we have considered the clinical progress of this disease worthy of record.

REPORT OF CASE

History.—Mrs. J. R. H., aged 35, white, domestic, was admitted to the service of Dr. B. A. Ledbetter, Oct. 8, 1916, complaining of "sore mouth and general weakness." There was nothing of significance in the family history. The patient had measles and whooping cough in childhood and typhoid fever one year before admission. She was married and had two children, both living and apparently well. She strenuously denied miscarriages, syphilis and leukorrhea. Until four months before, the patient had been in perfect health, doing housework and suffering no discomforts. About that time she first noticed that her gums were sore and swollen. She went to a dentist and had several teeth extracted. The gums seemed to heal, only again to become inflamed in a few weeks. Since then she had been gradually getting weaker, until a few days prior to admission, when she did not have sufficient strength to leave the bed. A loss of 15 or more pounds in the last month was noted. Her appetite was poor, and her bowels fairly regular. No vomiting nor expectoration of blood occurred. There was no rise in temperature and no pain, except from the teeth, and no cough.

Physical Examination.—The patient was poorly nourished and markedly anemic. The skin was of a sallow tint, dry and inelastic. The glands of the neck were enlarged. The teeth were badly kept, sordes was present, and there was marked pyorrhea. The teeth were loose and decayed, and several were missing. The tongue was dry and coated, and the mucous membranes were markedly anemic. The throat, nose, ears and heart were negative. The lungs showed a roughened breathing at each apex, but neither râles nor dulness. The abdomen was flaccid and relaxed. A large cicatricial scar from an old burn was noticed to the right of the umbilicus. The liver was not palpable. The spleen was much enlarged, extending to the midline and nearly as low as the umbilicus, and was rather hard and firm with a fairly sharp edge. The vaginal and rectal examination revealed nothing abnormal. The extremities and reflexes were negative.

Laboratory Reports.—There was a total leukocyte count of 83,330 per cubic millimeter, and a total erythrocyte count of 2,400,000 per cubic millimeter, with a hemoglobin of 30 per cent., making a color index of 0.62. Examination of the urine revealed a trace of albumin, but sugar, indican and acetone were not present. Microscopically, many fine and coarse granular casts, and a few pus cells were found. Both the original Wassermann test and the modifications were negative. Smears from the teeth revealed the *Endamoeba buccalis* in large numbers. A roentgenogram of the chest revealed very dense glands at the lung roots, with slight infiltration of both upper lobes.

Differential Blood Count: On examining a Wright stained blood smear, we were unable to agree on the type of mononuclear cell predominating. Some of the cells resembled myelocytes and others large lymphocytes. The cell in question was about the size of a myelocyte, but it had a nucleus that nearly filled its entirety, and showed only slight tendency to transition forms, and practically none of polymorphonucleation. The cytoplasm of these cells was finely granular with a marked tendency to basophilic stain. Slides were submitted to such pathologists and hematologists as Drs. Bass, Couret, Duval, Johns, Langford and Weis. The reports were about equally divided between a diagnosis of myelogenous and acute lymphatic leukemia. By a personal letter dated October 16, to Dr. J. D. Weis, Dr. Richard C. Cabot of Boston reported as follows:

"I think the cells in your slides of blood are large lymphocytes. I do not think that they represent the older stem cells, ancestors of red cells and white cells alike, though, as you know, one often gets these stem cells in leukemia. Neither do I believe that they represent neutrophilic myelocytes of the bone marrow series. I think they are the ordinary large lymphocytes of normal blood. I believe the case is one of so-called lymphoid leukemia, without much of any anemia, apparently."

Treatment.—This consisted of stimulation with strychnin, brandy, digitalis and forced nourishment. The patient rapidly became weaker and had a temperature ranging from 99 to 100 F. October 20 (the eleventh day in the ward), we noticed that there was an enlargement of the entire superficial gland chains over the entire body, the individual glands being the size of split peas. October 22, the patient voided and defecated involuntarily and refused all nourishment, and at 4:35 a. m., October 23 (the fifteenth day after admission to the ward), the patient died.

BLOOD FINDINGS

Date	Total Erythrocytic Count	Hemoglobin	Color Index	Total Leukocytic Count	Differential White Cell Blood Count (500 Count)				
					Polymorphonuclear Neutrophils	Polymorphonuclear Eosinophils	Lymphocytes	Myeloblasts	Transitionals Myelocytes
Oct, 9, 1916	2,400,000	30	0.62	83,330	7.8	1	5.2	78.8	7.2
Oct. 14, 1916	....	..	....	217,707	9.4	0.8	3.6	75	11.2
Oct. 17, 1916	....	..	....	312,000	4	...	2	84.8	9.2
Oct. 20, 1916	1,984,000	..	....	487,000	8	1	5.2	71.2	14.6
Oct. 22, 1916	1,890,000	25	0.67	716,600	5.8	1.2	8	62	23

Necropsy Report.—The necropsy was held by Dr. C. W. Duval, Oct. 24, 1916, twenty-nine hours postmortem.

Body: The skin was of a light lemon yellow hue, especially marked on the face and neck. The anterior surface from the chin to the pubes was thickly studded with pin point and larger subcutaneous hemorrhages (petechiae). These punctate hemorrhages were most marked over the abdomen, and were bluish black on the abdomen, but of a purple hue in other locations. The superficial lymph nodes in the inguinal, axillary and cervical regions were enlarged and freely movable.

Peritoneal Cavity: The omentum was peppered with large and punctate hemorrhages. The serous covering of the viscera contained numerous petechiae, and the mesentery, more especially that of the small intestine, was diffusely hemorrhagic. There was, however, no free blood in the peritoneal cavity.

Heart: Four warty excrescences were noted on the mitral valve, the larger being approximately the size of a small almond. One of these excrescences in particular had a roughened outer surface, and in places it would appear as though bits had previously broken off.

Lungs: Both organs were voluminous and crepitant throughout.

Spleen: At the upper and lower poles, there were to be seen nodular masses that pushed out far above the general diameter of the spleen. On section, these nodules were found to be well defined areas of infarction (anemic variety). The smaller areas of infarction were surrounded by a well defined zone of hemorrhage. The spleen itself, on section, was coarsely granular and opaque (pyoid), and its surface was grayish red.

Liver: This organ was enlarged, and scattered throughout the parenchyma were numerous opaque nodules embedded in the substance, not sharply defined, and measuring from 2 to 5 cm. in diameter (*myeloid tissue*).

Pancreas: This organ was firm, distinctly lobulated, and of a lemon yellow color.

Gastro-Intestinal Tract: Throughout the entire tract the mucosa was diffusely hemorrhagic. There was, however, no free blood in the lumen. The mucosa of the ileum was dark slate gray, while the mucosa of the other portions of the small intestine was light purplish red. The lymph follicles of the intestine were somewhat enlarged.

Kidney and Bladder: The kidneys were of enormous size and pale. On section, their normal markings were poorly defined. The mucosa of the bladder revealed numerous punctate hemorrhages.

Spinal Cord: The meninges contained punctate hemorrhages.

Bone Marrow: This was taken from the middle of the femur, and it was of a chocolate brown color.

Diagnosis.—1. Anatomic: (*a*) acute myeloid leukemia; (*b*) acute ulcerative endocarditis, and (*c*) infarcts of the spleen.

2. Microscopic: (*a*) chronic interstitial and parenchymatous nephritis; (*b*) bronchopneumonia, and (*c*) typical myelogenous leukemia.

COMMENT

There could be no doubt that the diagnosis of a leukemia was correct, and with the short duration and markedly increased white cell count of 716,000 in fifteen days, a leukemia of the most acute or malignant type. At first, with such a total blood count, enlarged mediastinal glands and disputed differential blood picture, one was inclined to make a diagnosis of the lymphatic variety. Later, with the marked increase in the total white cells and the appearance of many transitional types of myelocytes, one was disposed to favor myelogenous leukemia; but the diagnosis was established definitely only by the bone marrow findings.

WEBER'S SYNDROME

WITH REPORT OF A CASE *

G. B. HASSIN, M.D.
Attending Neurologist, Cook County Hospital
CHICAGO

Weber's syndrome means, clinically, a complete or partial paralysis of the oculomotor nerve combined with a contralateral hemiplegia. Pathologically, it signifies some lesion of one of the cerebral peduncles (the crus cerebri). The practical value of this syndrome lies in the possibility of precisely locating a brain lesion, since the presence of Weber's syndrome is a sure evidence of involvement of a portion of the brain — the peduncular region — that so far has been absolutely inaccessible to operative interference.

Weber's syndrome will be complete and pronounced when that part of the peduncle is involved which is adjacent to the oculomotor nerve, that is, the inner portion. Otherwise, the oculomotor nerve may be spared, and then, in spite of the presence of a peduncular lesion, the syndrome will be lacking and will have no value as a sign of localization. Cases of this type have been reported by Andral, and by Pepper and Packard. As a rule, however, the peduncular lesion results in both oculomotor and pyramidal tract involvement. It was described long before Weber's day. Thus, Mohr minutely reports this syndrome twenty-three years before Weber, and Green mentions it eleven years before Weber. In 1859, that is to say, four years before Weber's paper was published, Gubler, in speaking of paralysis alternans, describes a case of Luton in which a hemiplegia of the left side was associated with a right third nerve paralysis, as the result of a softening of the right cerebral peduncle. Yet none of these authors give so precise and complete a description as Weber, who in 1863 pointed out the anatomic, clinical and pathologic characteristics of a peduncular lesion, which Charcot in 1891 proposed to call the Weber syndrome. Weber's contribution was followed by a number of reports, some of which were purely clinical. In other words, they had not been substantiated by necropsies, as in Jelliffe's three cases and Zosin's case. Some of these reports represented a somewhat modified clinical picture.

To the modified type of Weber's syndrome belongs the so-called Benedikt syndrome in which the paralyzed side shows a tremor resembling that of paralysis agitans, chorea or athetosis and in which the lesion was found to be not so extensive in the peduncles as in the so-called tegmentum, the region above the latter (Canfield and Putnam, Mendel, Block and Marinesco, Charcot and Gilles de la Tourette, d'Astros, and Gierlich and Hirsch).

The study of the few pathologic reports pertaining to Weber's syndrome shows that this can be caused by softening (Mayor, Oyon, d'Astros), hemorrhages (Weber, Rickards, Leteinturier, Leube), posthemorrhagic cysts (Andral), tumors, as tubercles (Mohr, Green, Bouveret and Chapotot, Greiwe), gliomas (Sutton, Rosenthal, Pepper and Packard), sarcomas (Beck), new growths not identified (Callender, Sharkey, Touche), hydatid cysts (Du Camp), abscesses (Stiebel), and a revolver bullet (Guillain and Hauzel). Tumors were by far the most frequent cause of the peduncular lesion, especially tubercules and gliomas. A gliomatous growth was also found in the following case:

REPORT OF CASE

History.—A girl, aged 9 years, entered the Cook County Hospital, Sept. 8, 1916, in the surgical service of Dr. Morf. July 3 of the same year, that is to say, about nine weeks previously, she had suddenly been seized with vomiting, dizziness and a headache. The headache was so severe and continuous that it had caused her to cry out with pain. Two weeks after the onset of the disease, the mother noticed a drooping of the left upper eyelid which was followed six weeks later by weakness of the right arm and leg. In this condition she entered the hospital, with a ptosis of the left eyelid of seven weeks' duration, and a hemiplegia of the right side of one weeks' duration. The child had dysentery at the age of 3 and earache at the age of 4, but the mother could not tell whether there was a discharge from the ear. At the age of 7 the patient developed a kyphosis, though the records do not show its exact location. The father and mother, who are 37 and 36 years old, respectively, as well as three sisters and one brother, are all living and well.

Examination.—The left upper lid drooped, covering the major portion of the palpebral fissure. The patient could not raise it more than a quarter of an inch. The left eyeball did not move up or down or inward. The left pupil was dilated, and did not react to light or in accommodation. The left eye was turned outward, the external movements being the only ones remaining. The right corner of the mouth was slightly drooping, and the right arm and leg were totally paralyzed, revealing exaggerated reflexes as well as a positive Babinski sign, a positive Chaddock and a positive Oppenheim, but a negative Gordon reflex. The left side did not show any abnormalities. Sensibility was present on both sides. The fundi showed a bilateral papilledema. The heart, lungs, genito-urinary organs, mentality, speech, urine, spinal fluid, pulse, respiration and temperature were normal. A roentgenogram of the skull did not show the presence of a tumor.

---

* Owing to lack of space, a rather complete list of references to the literature has been omitted. This will appear in the author's reprints, a copy of which will be sent by him on request.

Thus, the examination revealed an external strabismus of the left eye, a total oculomotor paralysis of the same side, a contralateral hemiplegia with exaggerated reflexes, and a bilateral papilledema. It was a typical Weber syndrome caused, we thought, by a tumor of the left cerebral peduncle. As brain tumors in children are usually tubercles, a diagnosis of tubercle of the left cerebral peduncle was made.

Operation and Necropsy.—Dr. Morf thought it advisable to reduce the intracranial pressure by an operation in the left temporal region, which was done, Sept. 30, 1916, and was followed by the death of the patient two weeks later. The postmortem examination revealed a glioma that had completely destroyed on the left side the gyrus hippocampus, the cornu ammonis, the cerebral peduncle, and the left oculomotor nerve. It spread upward, involving the region of the tegmentum and part of the optic thalamus, and invading the pons and the medulla. The tumor spared the optic chiasm, the anterior perforated space, and the hemispheres, but caused total obliteration of the third ventricle, greatly reduced in volume the aqueduct of Sylvius and the fourth ventricle, and produced an enormous dilatation of the anterior horns of the lateral ventricles. Those portions of the tumor that involved the cornu ammonis, the peduncle, the optic thalamus and the pons were exceedingly vascular and hemorrhagic, while the portions that invaded the posterior portion of the pons and the medulla were less vascular and showed an enormous number of large, well-developed glia cells. The walls of the vessels, especially in the peduncular region, appeared greatly thickened and hypertrophied, and contained few glia cells. Hemorrhagic foci were numerous, covering the entire field of vision in some specimens. Thus, the glioma was very extensive and evidently started in the hippocampal gyrus, which revealed evidences of deeper destruction than any of the regions previously mentioned, with the possible exception of the left oculomotor nerve and the left cerebral peduncle.

COMMENT

A case of this type affords excellent opportunities for studying the function of the hippocampal region, in order to discover its possible relation to the functions of taste and smell, an investigation which, unfortunately, was not made in this case. The extensive involvement of the neighboring regions, as the optic thalamus, the pons, etc., did not show any clinical symptoms that were exclusively those of a Weber syndrome. In a case of Boinet, a glioma of the optic striate region pressed on the chiasm, the optic tract, the left cerebral peduncle, and the upper third and lateral half of the pons. Clinically there was a Weber syndrome with a bilateral ophthalmoplegia and pseudobulbar paralysis. Somewhat similar cases were reported by Mingazzini. One patient showed a "perioptopeduncular" tumor of sarcomatous origin, which started from the hypophysis, secondarily involving the optic thalamus and the peduncles. The clinical picture revealed involvement of all the nerves of the base of the brain, a tendency to fall to the right, and twitchings in the left arm.

These cases demonstrate that a tumor of the peduncular region may give symptoms not exclusively confined to Weber's syndrome, if the neighboring areas are involved. Yet, in our case the clinical picture was that of a purely classical Weber syndrome in spite of the involvement of the tegmentum when, as I have previously mentioned, there should have been a Benedikt syndrome, that is to say, tremor of the paralyzed side combined with a contralateral oculomotor paralysis — symptoms which, in this case, were absent. They were also absent in the case of Greiwe, in which the tegmentum was totally destroyed by a tubercle. Another remarkable feature in our case was the patient's excellent mental condition, regardless of the fact that a large portion of the brain was totally destroyed. Absence of any mental symptoms was also observed by the majority of authors in cases of Weber's syndrome that were caused by softening or hemorrhages. In those patients in whom impairment of the intelligence was present, the symptoms could not possibly be ascribed, as d'Astros justly remarks, to the peduncular lesion itself; they should, he thinks, be ascribed rather to the accompanying cerebral arteritis or to syphilis.

UTERINE RUPTURE FOLLOWING ANTERIOR HYSTEROTOMY

ROSCOE R. KAHLE, Ph.B., M.D.
Surgeon, Grant Hospital
COLUMBUS, OHIO

Spontaneous intraperitoneal rupture of the uterus during labor is, very fortunately, of rare occurrence. Contrary to early teaching, it occurs most frequently in multiparas. An impaired integrity of the uterine wall from repeated pregnancies is more frequently a causative factor than obstructed labor. This may well be borne in mind as, I believe, the popular notion would lead us to suspect this calamity more particularly in the presence of obstruction.

The vulnerable scar, following a cesarean section, operates strongly as a predisposing cause of uterine rupture. Indeed, the likelihood of a tear through the old scar has found expression in the dictum, "Once a cesarean, always a cesarean."

Recently, a surgical procedure, known as anterior hysterotomy, has been brought forward as an easy, safe and sane method of inspecting the interior of the uterus. To me it seems only easy. The following case report is convincing argument in favor of "cleaning up" a miscarriage case in the old-fashioned way:

REPORT OF CASE

History.—Mrs. C., aged 23, married four years, referred by Dr. W. D. Moccabee of Cardington, had a good family history, and she had always been well until a miscarriage at three months occurred in December, 1915. At this time, that hemorrhage following fetal expulsion might be arrested, the abdomen was opened, the uterus incised, and the offending placenta removed (a cesarean operation after delivery!). Operative recovery was prompt. Eighteen months later, the patient came to labor at full term. Pelvimetry bespoke ample pelvic measurements. The wise suggestion of her physician, that she enter a hospital for confinement, was rejected. Mild labor pains appeared irregularly for about forty-eight hours, after which they did not return. I saw the patient in consultation, Jan. 28, 1917. There had been no labor pains for several hours. Dr. Moccabee stated that he suspected uterine rupture through the old scar, although the symptoms were quite atypical. The pulse was rapid, but of good volume. Gastric dilatation was in evidence. There were no fetal heart sounds. Profound shock was absent, and the patient said she felt quite well. The uterus and fetus could not be separately palpated through the abdominal wall. The patient stated that she heard something crack and felt something give way about the time her pains stopped.

She was removed to Grant Hospital, where an anesthetic (ether) was administered, and, after the uterus had been explored to verify our diagnosis, abdominal section was made. The dead baby was removed from the peritoneal cavity, hysterectomy was rapidly performed, and a quart of physiologic sodium chlorid solution administered intravenously. An uninterrupted recovery supervened.

Specimen.—Examination of the uterus revealed that it had yielded at the old hysterotomy scar. This was not remarkable for however carefully the incised uterine wall may have been repaired, Nature frowned on the job. Muscular union was all but nil, the infolding endometrium approximating the peritoneum—an ugly rent, indeed.

SUMMARY

1. Anterior hysterotomy, in a child-bearing woman, is not an innocent procedure.
2. When uterine rupture occurs through scar tissue, prognosis is more favorable because there is less likelihood of severe hemorrhage.
3. The vulnerability of a cesarean scar makes it desirable for such patients to enter a well-equipped hospital for all future deliveries.

FROSTBITE AS A PREDISPOSING FACTOR IN CARCINOMA OF THE EAR

RICHARD L. SUTTON, M.D.
KANSAS CITY, MO.

Pusey has called attention to the important part played by long standing, dry seborrhea in the production of senile keratoses and similar precancerous lesions of the skin, and Heidingsfeld has shown that cicatricial tissue frequently serves as a starting point for cutaneous carcinoma.

The fact that areas of skin that have been subjected to frostbite, and especially to repeated frostbite, are abnormally susceptible to cancerous involvement has not, however, been sufficiently emphasized. The parts commonly involved are the ears, particularly the helixes, and the cheeks. The great frequency with which these areas are attacked can be appreciated only by a study of a considerable number of case histories. Of forty-six cases of seborrheic keratosis involving the ears and cheeks, examined during the twelve months elapsing Nov. 1, 1917, twenty-seven gave a history of frostbite. Of the twenty-seven, twenty-one presented one or more malignant growths on the affected areas. The majority of the seborrheic keratoses were of the keratoid type. Almost 90 per cent. of the carcinomas were of the basal cell variety. In three instances both the basal and squamous cell varieties were represented.

Judging from the result of my own observations, it appears that repeated exposure to very low temperatures tends also to reduce local resistance to the progress of the malignant growth, and thus becomes a factor in prognosis as well as in etiology.

The most important prophylactic measure is, of course, adequate protection of the parts commonly attacked. Should keratoses develop, the frequent application of an ointment containing small amounts (from 1 to 5 per cent.) of salicylic acid may be tried. In some instances, double this proportion of sulphur may also be advantageously added. In more advanced cases, suspiciously or frankly malignant, radium usually serves admirably, and possesses the great advantage of leaving the skin in a practically normal condition.

In attacking squamous cell growths of the ear, and especially if the associated lymph nodes are involved, radical excision is, in my experience, the method of choice.

A STATISTICAL STUDY OF LEPROSY IN THE PHILIPPINE ISLANDS

FROM THE HISTORIES OF TEN THOUSAND CASES ISOLATED IN THE CULION LEPER COLONY

OSWALD E. DENNEY, M.D., D.T.M.
Chief, Culion Leper Colony
CULION, P. I.

On the theory that facts of interest and of possible bearing on the transmission of leprosy might be obtained from a study of the personal histories of a large number of lepers, an investigation has been made of the "individual records" of each leper on his admission to the Culion Leper Colony.

The histories, which, of necessity, are very brief, contain, in addition to the name of the individual, the age, sex, nationality, race, birthplace, last place of residence, date of admission to the colony, marital relation, family contact history, probable duration of the disease, and a brief description of the physical condition of the patient at the time of admission.

TABLE 1.—AGE AT WHICH INFECTION IS ASSUMED TO HAVE TAKEN PLACE

Culion			Hawaii

	10,425				1,060	

Since a large number of the lepers of the Philippine Islands have only a slight knowledge of the simplest principles of hygiene and sanitation, questions regarding their views of the possible source of their infection bring little, if any, information worthy of serious consideration.

Since we lack exact knowledge of the method of transmission of the disease, exact knowledge of the time at which infection takes place would be of great value in the study of individual cases. Table 1, showing the ages at which infection is assumed to have taken place, is only relatively correct, since the period of incubation of leprosy is unknown and therefore has not been considered. The figures are based on the time at which the first symptom of the disease was recognized.

The remarkable similarity between these figures and those obtained by McCoy[1] in the Hawaiian Islands warrants their comparison at this point. The ages obtained from the Hawaiian statistics, it should be noted, are reckoned from the time of apprehension and not from the approximate date of infection.

---

[1] McCoy: A Statistical Study of Leprosy in Hawaii, Pub. Health Bull. 66, 1914.

Twenty-nine per cent. of the lepers segregated in Culion have given a definite history of previous contact with at least one leper relative. This percentage excludes a large margin of error, since it is a frequent occurrence for a leper on admission to give a negative family contact history. Then months or years later, a brother, sister, cousin or some other relative may be admitted as a leper in whom the existence of the disease was not suspected when the first relative was isolated.

In a study of the lepers giving a history of contact with only one leper relative, there were found certain significant facts about the distribution of the infection among the members of the families. They appear in Table 2.

TABLE 2.—DISTRIBUTION OF LEPROSY AMONG MEMBERS OF FAMILIES

Relative Who Had Leprosy	Lepers	
	No.	Per Cent.
Mother	106	4.77
Father	145	6.53
Son	113	5.09
Daughter	58	2.61
Brother	546	24.57
Sister	245	11.02
Nephew	85	3.82
Niece	44	1.98
Aunt	79	3.55
Uncle	130	5.85
Wife	17	0.75
Husband*	23	1.03
Grandfather	5	0.22
Grandmother	6	0.27
Grandson	12	0.54
Granddaughter	5	0.22
Son-in-law	1	0.04
Cousin	602	27.05
Total	2,222	99.92

* As has already been explained, there is a definite and unavoidable error in these figures. Since they are based on the records of lepers isolated in Culion only, no allowance has been made for the leper relatives remaining alive or dead in the provinces. For example, seventeen wives and twenty-three husbands were lepers, the unaccounted-for wives dying before their husbands were isolated in Culion.

If these cases are viewed from another standpoint to show a possible relationship between sexes, the data given in Tables 3 and 4 are obtained.

TABLE 3.—CONTACT BETWEEN LIKE SEXES

Persons Infected	No.	Per Cent.
Mother and daughter	81	4.48
Father and son	165	9.12
Brother and brother	398	22.00
Sister and sister	124	6.85
Uncle and nephew	144	7.96
Aunt and niece	60	3.32
Grandfather and grandson	9	0.49
Grandmother and granddaughter	6	0.33
Cousins, like sexes	117	6.47
Total, like sexes	1,104	61.02

TABLE 4.—CONTACT BETWEEN UNLIKE SEXES

Persons Infected	No.	Per Cent.
Mother and son	106	5.85
Father and daughter	70	3.87
Brother and sister	269	14.87
Uncle and niece	60	3.32
Aunt and nephew	74	4.09
Grandfather and granddaughter	3	0.17
Grandmother and grandson	10	0.55
Cousins, unlike sexes	72	3.97
Husband and wife	40	2.21
Son-in-law (and mother-in-law)	1	0.05
Total, unlike sexes	705	38.95
Cousins, sex contrast not known	413	
Final total	2,222	

If we assume, in these instances, that the disease has been transferred from leper to relative, nearly two thirds of the cases, exclusive of the cousins whose records failed to show the sex of the other infected cousin, are between relatives of like sexes. Notable is the record of contact among brothers and among sisters, which shows 522 cases of the disease transferred presumably from brother to brother and from sister to sister, in contrast to 269 cases of assumed transmission from brother to sister, or vice versa.

Rearranging these tables in order that a comparison may be made with somewhat similar statistics from Hawaii, and abridging the Hawaiian table to show family contacts only, we obtain the data given in Table 5.

TABLE 5.—COMPARISON OF LEPROSY AMONG RELATIVES IN CULION AND HAWAII*

	Culion		Hawaii	
	No.	Per Cent.	No.	Per Cent.
Fathers or mothers	251	11.30	117	37.02
Grandparents	11	0.49	6	1.89
Grandchildren	17	0.77	1	0.31
Sisters or brothers	791	35.61	102	32.27
Sons or daughters	171	7.69	12	3.79
Uncles or aunts	209	9.41	24	7.59
Cousins	602	27.10	18	5.69
Nephews or nieces	129	5.80	8	2.53
Husbands or wives	40	1.80	28	8.85
Totals	2,221	99.97	316	99.94

* The percentages are not from the original but are here calculated for convenience. The figures are subject to the error explained in the footnote to Table 2.

In addition to the lepers giving histories of contact with one leper relative, there were 182 families in which occurred infection of three or more members, distributed as shown in Table 6.

TABLE 6.—DISTRIBUTION OF FAMILIES IN WHICH LEPROSY OCCURRED IN THREE OR MORE MEMBERS

Members of One Family Infected	No. of Instances
8	1
7	2
6	5
5	9
4	35
3	130

The distribution of infection among the members of the individual families is shown in Table 7, from which it will be seen that the most frequent cases of infection among relatives were among three cousins, this combination being recorded twenty-seven times. More than half of the individuals infected were brothers and sisters, of whom 130 gave histories of contact with ninety-seven leper parents or grandparents, while 196 brothers and sisters gave no history of contact with leper parents or grandparents. Eighty-five cousins gave histories of contact with leper cousins only.

Of the 10,425 lepers admitted to Culion, 3,674, or 34 per cent., were married before admission. Of the latter number only forty, or 1 per cent., represent instances in which both husband and wife were known to be lepers.

The distribution of the disease among the tribes is given in Table 8.

In the Philippine Islands, as elsewhere, leprosy more frequently affects the male than the female. Of those segregated in Culion, 66.7 per cent. have been of the male sex.

The admission records show that the attempt to separate the cases into types of disease has proved unsatisfactory, as some of the cases have been classified as "anesthetic" or "tubercular" from the most pronounced symptom only, while the description of the cases show them to be, in some cases, "mixed." The larger majority of the cases, however, have been "tubercular" or "nodular," with the "mixed" cases coming second in point of numbers.

According to computations from records of 5,000 consecutive deaths, the average duration of leprosy, that is to say, the period existing between the time of recognition of the first symptom of the disease, and death, is 7.332 years. The longest duration of the disease of which authentic record was found is forty-eight years, the patient being a woman of 63 now living, who has spent eight years in Culion.

	Total Members Infected, 627											

In the ten years since the beginning of segregation of lepers in the Philippine Islands, 357 babies in Culion have been born of leper parents. Of these, 166, or 46.5 per cent., have died, twenty-four, or 6.7 per cent., being stillborn, fifty-nine, or 16.5 per cent., dying before reaching the age of 1 month, forty, or 11.2 per cent., dying before reaching the age of 3 months, and the remainder of the 166 living less than three years.

Thirty-seven of the 357 babies were released from Culion at early ages, after they had been examined clinically and bacterioscopically and had been reported not to be lepers. One of these was returned to the colony at the age of 4 years as a leper. Of the remaining thirty-six, little is known save that several died during an epidemic of bacillary dysentery in the institution in which they were temporarily placed.

Each of the 154 children remaining in Culion has been examined repeatedly both clinically and bacterioscopically. Sixteen, or 10.4 per cent., are lepers.

On several occasions, when lepers in the provinces were collected for segregation, leper mothers were found who could make no arrangements for the care of their babies, in which cases the infants were brought to Culion. Of nine of these children isolated with their mothers, three have died, one has been returned to the provinces, and five remain in Culion. Four out of these five are lepers, having been exposed to infection for from seven to ten years.

COMMENT

Granting that the *Bacillus leprae* Hansen, or the *Mycobacterium leprae*, is the causative agent of leprosy, and that no organism can arise de novo, the conclusion is drawn that the disease leprosy arises in an individual as the result of heredity or contagion. The word "contagion" is here used in its broad sense as the transmission of a disease from one person to another by direct or indirect contact.

It is acknowledged, in a scientific sense, that no parasitic disease can be inherited, although infection of the ovum or spermatozoon is possible, as well as a hereditary predisposition to leprosy. The fact, however, that 71 per cent. of the lepers segregated in the Culion Leper Colony came from families in which there was only one case of leprosy recognized, and that only a small proportion of the remaining 29 per cent. represent contact between parent and child, would tend to confirm the already firm belief that heredity plays an unimportant rôle in the transmission of leprosy.

It is to be regretted that, in the study of the histories of the 10,425 patients admitted to the Culion Leper Colony, no facts were found which furnished conclusive evidence on the transmission of the disease. It is interesting, however, to consider inversely the relation of certain of the facts obtained and the now considered theories of the transmission of leprosy.

Hansen is said to have remarked, "There is hardly anything on earth, or between it and heaven, which has not been regarded as the cause of leprosy." While the mystery of the etiology of the disease has been solved by Hansen, practically every thing and condition has since been considered in an effort to demonstrate the transmitting agent.

Climatology.—Nothing obtained from this study has demonstrated that the local climatic conditions either predispose to the disease or directly affect the transmission.

Local Geographic Distribution.—While the great majority of the lepers have come from the seacoast, it must be understood that the population of the Philippine Islands is, to a large extent, distributed along the seacoast. The mountain tribes, in spite of their relative inaccessibility, are not free from the disease, several of them being represented in the colony.

Air and Dust.—While the histories taken do not consider the possibility of transmission by air and dust, it is not without significance that in the ten years since the opening of the Culion Leper Colony, only two employees of the colony have developed the disease. One of these is a Caucasian ecclesiastic who was pronounced a leper after five years of exposure, and the other, a Filipino laborer who was pronounced a leper at the end of a year's employment in the colony. The latter patient comes from an infected family, having a cousin who was a leper for several years previous to the laborer's isolation. The average number of nonleprous employees in the colony is 200, nearly thirty of whom have been on the reservation for ten years.

Food.—Rice and fish comprise a large proportion of the Filipino diet. As each member of the family partakes of a fare almost exactly similar to that of the other members, it is difficult to conceive of how one might be infected to the exclusion of other members of a frequently large family. It is therefore negatively concluded that neither the native diet, nor any particular article of food has any relation to the transmission of leprosy, aside from the general predisposition to disease which may accompany the ill-nourished condition of the bodies of many Filipinos.

Sexual Transmission.—The fact that but 1 per cent. of the consorts of married lepers have developed the disease would tend to show that the sexual act, as such, has little, if any, bearing on the tranmission of leprosy.

By consideration, largely with negative statements, there have been eliminated from this discussion some of the more generally considered possible means of transmission of leprosy. There remain for consideration transmission through physical contact and through secondary parasites.

Physical Contact.—The large proportion of the cases of infection which have presumably been transmitted among brothers and sisters, or among cousins, would suggest physical contact as an important factor in the transmission of the disease. On the contrary, the relatively small percentage of transmission between parent and child, or the smaller percentage between husband and wife would suggest that even prolonged and intimate contact alone is not sufficient.

Secondary Parasites.—The bacillus of leprosy has, of itself, no known powers of penetration. It is therefore reasonable to believe that should it be transferred from person to person by a secondary parasite, this parasite must habitually implant the bacillus in a suitable place. One is then forced to exclude all parasites having no powers to penetrate the human skin, which is the part most likely to be habitually attacked.

The mosquito is physically capable of transplanting the bacillus of leprosy beneath the human skin. There is, however, nothing in the life history of the mosquito to lead one to suspect that it would bite and infect with leprosy one member of the family, to the frequent exclusion of all others, or to select and infect brothers and sisters to the exclusion of other relatives. Nor does anything in the life history of the mosquito explain the presumed transmission of the infection between like sexes. By similar reasoning, flies, ticks, lice and bedbugs may be excluded as probable agents of transmission, provided each member of a household is similarly exposed to infestation.

The theoretically ideal transmitting agent, then, must have the ability to penetrate the human skin, to select by preference certain members of the family, brothers, sisters or cousins, and to transplant the bacillus preferably from one sex to a like sex. It also includes the element of physical contact.

CONCLUSIONS

1. One half of the cases of leprosy segregated in Culion have been diagnosed in adolescence.
2. Twenty-nine per cent. of the lepers gave definite histories of contact with leper relatives. No record has been made of contact with lepers other than relatives. It is probable that carefully taken histories would have revealed contact histories for all the lepers isolated, since the disease is widespread throughout the islands.
3. Thirty-five per cent. of those giving histories of contact with a single leper relative were sisters and brothers, 27 per cent. were cousins, while 11 per cent. were leper children and 7 per cent. leper parents.
4. In the occurrence of infection of two or more relatives, the majority of cases were among members of like sexes, the noteworthy exception being the number of mothers and sons infected in excess of the number of mothers and daughters.
5. Numerous records show multiple infection within families, spreading over one, two or three generations, more than half of the infected persons being brothers and sisters.
6. In 1 per cent. of the lepers who were married before admission to Culion, the infection was between husband and wife.
7. The male sex is more frequently infected.
8. The average duration of leprosy is 7.3 years.
9. Mortality among children born of leper parents is high. The incidence of infection among children living in the colony for from one to ten years is 10.4 per cent.
10. Infection of children born of parents, one of whom is a leper, and living among lepers for from seven to ten years, is 44 per cent.
11. From this study, nothing of importance, other than circumstantial evidence, has been learned regarding the transmission of leprosy.

Additions to Registration Area.—Maryland, Virginia and Kentucky have recently been added to the list of states in the Registration Area for births of the United States. Conscription and enlistment in the Army have shown the need for accurate birth statistics and have stimulated interest in this important matter. Tests by agents of the U. S. Census Bureau of the completeness of birth registration in Virginia and Kentucky gave a rating of over 90 per cent., which is the figure required for registration. Similar tests are being made in Indiana and New Jersey, with North Carolina, Ohio and Utah to follow, and within the next two years it is expected that the Registration Area will comprise at least two thirds of the population of the United States.

LEIOMYOMA OF THE APPENDIX

REPORT OF TWO CASES

LAURANCE D. REDWAY, M.D.
Pathologist, Pathologic Laboratory, the Roosevelt Hospital
NEW YORK

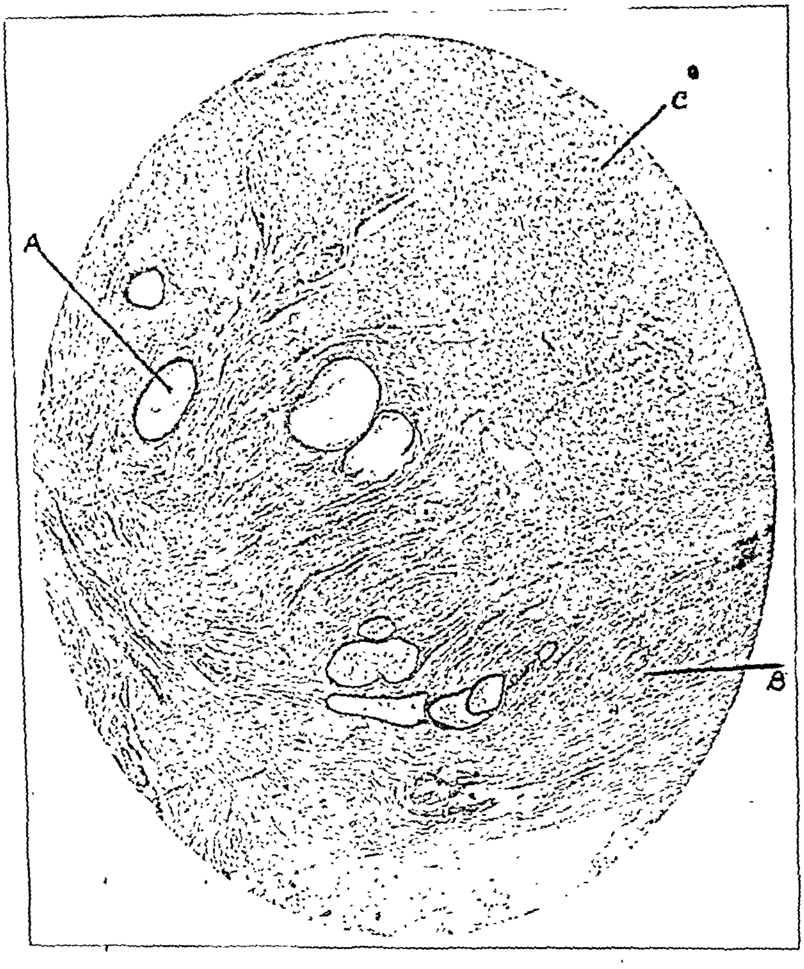
Both of these tumors were discovered in the course of a routine pathologic examination of the surgical specimens. In neither case was there any clinical evidence indicating or suggesting their presence.

REPORT OF CASES

Case 1 (C-1184).—*Clinical Data.*—Mrs. S. B., aged 40, was admitted with symptoms of general pelvic inflammation. Operation was performed the day following admittance, consisting of removal of the uterus, both tubes, one ovary, and the appendix. Recovery was uneventful.

Surgical Findings.—The uterus was distorted by the presence of many fibroids of all varieties, extending from the fundus to the cervix. The lumen was partially occluded by submucous fibroids and blood clot. Both tubes were swollen, the distal ends closed. The ovaries were cystic. The appendix was small. The distal end was kinked, the color, normal. The lumen was obliterated.

Pathologic Findings.—There were multiple fibromas of the uterus. No endometrium was seen. The tubes showed moderate chronic inflammatory reaction. Many small round cells were noted. The ovary was very fibrous, with numerous cysts. The lumen of the appendix had been entirely obliterated. The muscular coats showed some fibrosis, moderate in amount. There had been marked proliferation of the muscle tissue. This growth had progressed to the extent of obliterating the lumen. The mucosa had apparently suffered pressure atrophy to the extent shown in the illustration, except in isolated areas where it still persisted as the lining wall of small cysts.



Leiomyoma of appendix: *A*, remains of mucosa; *B*, muscle wall; *C*, tumor mass. Notice the arrangement of nuclei of the tumor, like columns of troops.

Case 2 (SA-2610).—*Clinical Data.*—Mrs. A. G., aged 36, was admitted complaining of pain in the right lower quadrant, of five months' duration. The onset was not acute. Recently, there had been pain in the left lower quadrant; menstruation was irregular; leukorrhea was present; there had been no pregnancies. Operation was followed by uneventful recovery.

Surgical Findings.—The uterus was normal in size and consistency, but was held downward, backward, and to the left by firm adhesions. The left tube was partially adherent to the back of the uterus, and was not enlarged or diseased. The right tube and both ovaries apparently were normal. The appendix was found to be surrounded by many firm adhesions. It was enlarged, angulated 3 cm. from the tip, and the distal portion for about 1 cm. was constricted, firm, and paler than normal. On the opening of the peritoneal cavity through a median incision, the entire abdominal contents were found to be covered by a transparent, membranous veil, making it appear as though all the viscera were retroperitoneal.

Pathologic Findings.—Only the appendix was removed. This measured 3.5 cm. in length, by 0.75 cm. in diameter. The serous surface was grayish pink. The proximal end showed a patent lumen, partially necrotic, and sloughed mucosa, the submucosa heavily fibrosed, and showed many small round cells throughout, some thickening of the muscularis, and slight fibrosis of the serosa.

At the distal end there were observable some remains of the original muscularis as such, but this had hypertrophied so that the mass of muscle tissue completely filled and obliterated the lumen. Van Gieson's stain revealed some fibrous growth, but the large bulk of the obliterating mass was smooth muscle tissue. The mucosa was not observed, and had probably undergone complete atrophy. The serosa was normal.

SUMMARY

Both patients were women, aged 36 and 40, respectively. The presence of uterine fibromas was noted in one, but not ascertained in the other. Both appendixes were removed, one as a routine surgical procedure, the other on clinical evidence of chronic inflammation. Microscopically both appendixes showed evidence of chronic inflammation of long standing, and in both the seat of the tumor mass was in the extreme distal end. The pseudo-adenomatous condition of the one is interpreted as an intermediate stage in a process affecting the mucosa, and one which has gone on to complete obliteration in the other.

Ancient Prescribing.—Ancient Greek prescriptions were of a curious character, according to our present ideas. For instance, they directed that no medicine should be administered to a sick cow by a woman; they lauded cabbage as a cure for almost every ill; placed great stress on the number 3 and supposed medicines to be more active when 3 drams, 3 ounces or 3 times any quantity was given, and they at the same time directed the repetition of cabalistic words and incantations.—Wall, *The Prescription.*

BRACHIAL NEURITIS AND SCIATICA

HUGH T. PATRICK, M.D.
Clinical Professor of Nervous and Mental Diseases, Northwestern University Medical School
CHICAGO

A misapprehension as to the frequency of brachial neuritis and of sciatic neuritis or sciatica I believe to be quite general. At any rate, I do know that in the profession at large, as I meet it, the diagnosis of these diseases is made altogether too frequently.

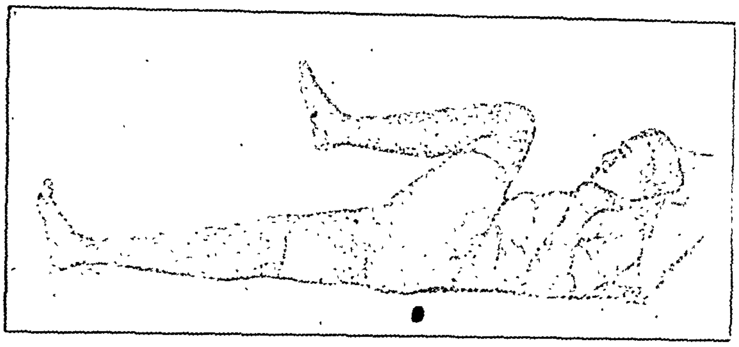


Fig. 1 (Case 1).—Arthritic side, showing free flexion of thigh.

BRACHIAL NEURITIS AND SHOULDER ARTHRITIS

A careful review of my records (private practice) for the last ten years shows that, of the patients referred to me supposedly with brachial neuritis, only about one in ten really had it. Approximately four fifths were cases of arthritis of the shoulder joint. The other one tenth was made up of cases of bursitis, syphilis, neoplasm, cervical rib, postherpetic pain, osteomyelitis, cervical caries and cervical arthritis. Indeed, when a patient states that he has for some time been troubled with neuritis of the shoulder or arm, one is pretty safe in assuming that it is something else, probably arthritis.

Why should so many physicians have made an erroneous diagnosis of brachial neuritis? Principally, I think, on account of the relative prominence of pain, because this pain was not distinctly localized in the shoulder joint and probably because they did not sufficiently examine the patient: A careful examination seldom leaves one in doubt.

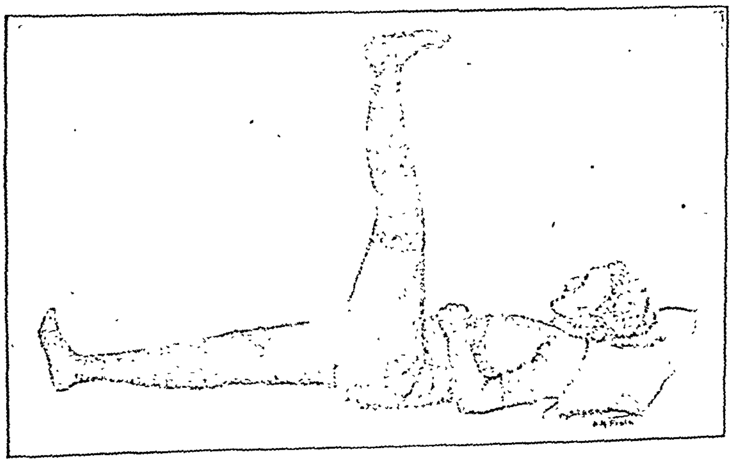

Fig. 2 (Case 1).—Arthritic side; no Lasègue sign.

Neuritis is rare; the pain is constant, is influenced not at all or but little by passive movement of the shoulder, and is generally influenced not greatly by active movement, though the patient moves the arm carefully. Ordinarily, the suffering is intense, such as never occurs in arthritis except in the worst cases, when the patient cannot move the joint at all. Intermittent, grumbling pain is very, very rarely that of neuritis. There is distinct, generally exquisite, tenderness of the cords of the brachial plexus or of the nerve trunks or of both. In some cases there is distinct though slight tactile anesthesia and sometimes surface hyperesthesia—more properly speaking hyperalgesia. Tingling or subjective numbness of fingers or forearm is frequent. The deep reflexes of the arm are diminished or lost. The disease is nearly always self limited. It lasts a few weeks or a few months (in bad cases from six to nine months), there is definite recovery, and it seldoms recurs.

Arthritis of the shoulder, on the other hand, is very common, and the pain fluctuates more or less, even when very bad. In the less severe cases it is intermittent. Not only is it intermittent within the twenty-four hours, but the patient has his good and his bad days. Often the pain seems to be influenced by the weather, and for some reason it is apt to be more annoying at night. As before stated, often the pain is not distinctly localized in the shoulder joint. In a great many cases it is felt chiefly *at about the insertion of the deltoid*. For this I have no adequate explanation, but I know that it is very misleading. More than once I have known it to lead to a diagnosis of osteomyelitis. Sometimes the pain is rather diffuse, radiating up into the neck and down the arm. This pain in the neck and down the arm I am quite sure is often due to concomitant arthritis of the cervical spine, the nerve roots being irritated where they pass out through the intervertebral foramina. In some cases of shoulder arthritis alone I have no doubt that the nerve trunks may be involved where they pass close to the joint.

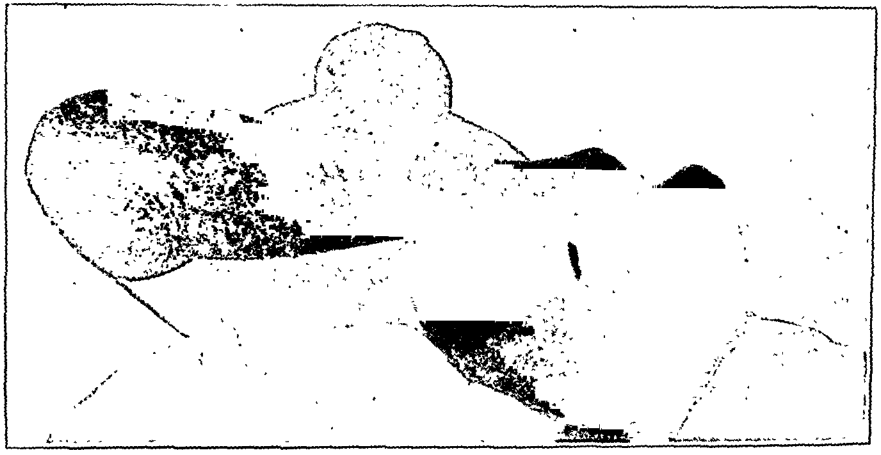

Fig. 3 (Case 1).—Normal side; leg alm ost horizontal; that is, no fabere sign.

The striking feature, however, of the arthritis cases is that in whatever part the pain may be felt, there are certain movements of the shoulder joint, active or passive, which cause pain. These are by no means always the same; but by all odds the most frequent is adduction of the humerus with retraction and internal rotation, the movement involved in crossing the forearms behind the back. Consequently the woman has difficulty in fastening her skirts and her waist behind, and the man in putting his hand into his hip pocket. Another good test movement is to extend the arm straight upward and then rotate it as if operating a screw driver. In the examination of such a case, movements in different directions, with the arms in different positions, should be carried out against resistance. For instance, with the arms extended horizontally and parallel in front of the upright trunk, the hands are pushed toward each other, away from each other, upward and downward *against resistance*. With the arms extended sidewise, making a cross with the body, resistance movements are made upward, downward, forward and back, etc. One or more of these movements will be pretty sure to be painful, which would not be the case in mild neuritis. But it must be emphasized that in many cases of subacute and chronic arthritis, many movements or most movements are entirely painless. I have had a number of patients who could play golf with perfect freedom; and such exercises as hammering, sawing, rowing and sweeping may have no immediate influence on the pain. Likewise, in the chronic or subacute cases, local tenderness may be but slight or even absent. Of course in acute arthritis practically all movements of the joint are painful, and there is limitation of passive motion, neither of which conditions obtains in neuritis.

Of very considerable assistance in the diagnosis is the state of the deep reflexes. These are uniformly brisk, and sometimes considerably exaggerated. Even when the muscles are quite atrophic and the appearance of the arm would indicate loss of the deep reflexes, the wrist jerk and triceps jerk will be found to be quite lively, more so than those of the well side. The same, as a rule, applies to the scapular jerks.

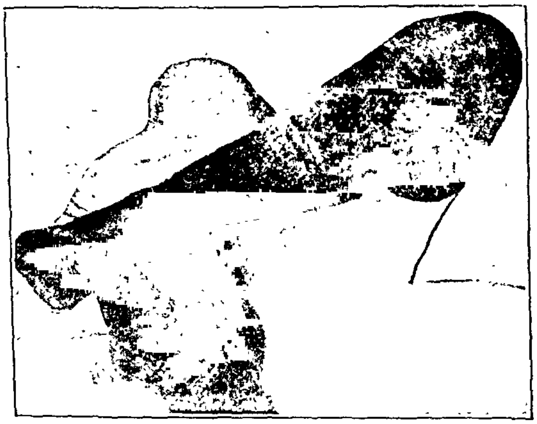

Fig. 4 (Case 1).—Arthritic side; knee cannot be normally depressed: fabere sign.

Wasting of shoulder and arm muscles sometimes leads the observer astray. There seems to be a common feeling that atrophy means nerve trouble. Consequently wasted deltoid, biceps and triceps apparently lend color to the view that the shoulder pain is neuritic. Just how arthritis causes atrophy of muscles moving the affected joint is still matter for speculation; but the fact of its general presence is of daily observation. The atrophy may be very marked and the arthritis relatively mild. I once saw a boy with mild multiple arthritis in whom the muscular wasting was so obtrusive that the case was thought to be one of advanced progressive muscular atrophy. Indeed, I have known men high in the profession to be misled by this arthritic atrophy.

There are two more signs of value: signs, I regret to say, that seem to be infrequently looked for. These are fever and leukocytosis. In very mild and chronic cases they may not be found, but such are exceptional. Repeated examinations, especially when the pain is at its worst, will nearly always show at one time or another (sometimes uniformly) a slight rise of temperature (from 99 to 100 F.) and a slight increase in the leukocyte count (from 8,000 to 9,000 or 10,000, occasionally 12,000). These two signs naturally lead us toward the conclusion that the arthritis is of infectious origin, and this conclusion is supported by the fact that less obtrusive arthritis elsewhere can often be found. Even when the patient avers that he has no other trouble, painstaking inquiry and examination frequently will show that his statement is inaccurate. Other joints oftenest involved are the opposite shoulder and the articulations of the cervical spine. Perhaps next in order come the lumbar and the dorsal spine, the hip and the finger joints. Furthermore, it is not so very unusual to find a coexistent indurative headache or soreness and tenderness of the occipital or suboccipital region, troubles I believe to be almost invariably due to infection, the focus generally being somewhere in the head or the throat. Of like significance is tenderness of the trapezius or other neck muscles — a fairly frequent concomitant.

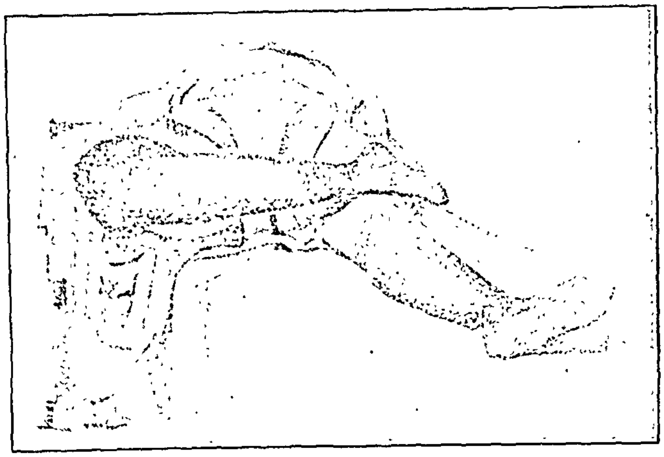

Fig. 5 (Case 1).—Same as Figure 3.

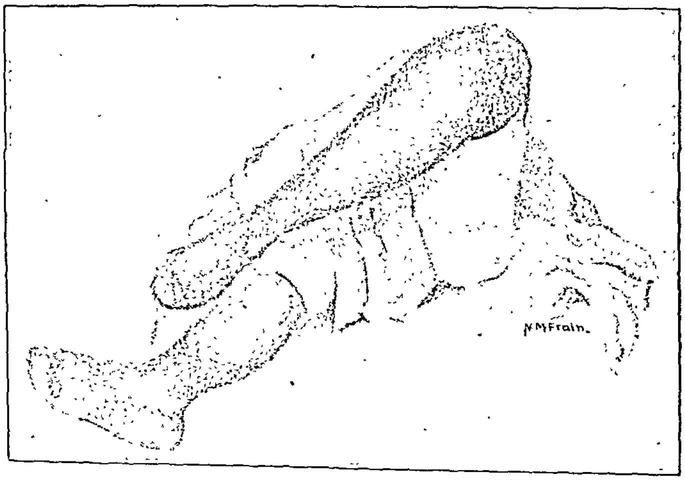

Fig. 6 (Case 1).—Same as Figure 4.

SCIATICA AND ARTHRITIS OF THE HIP

Thirty-odd years ago Dr. L. Putzel of New York called to my attention the frequent mistaking of chronic arthritis of the hip for sciatica. Since that time I have been interested in observing how much more common is the arthritis than sciatica, and how frequently an erroneous diagnosis is made.[1] Outside of large charity hospitals I believe sciatica to be a relatively rare disease, while arthritis of the hip is one of the most common. This is no new assertion. Many years ago that wonderful observer Jonathan Hutchinson expressed the opinion that a certain number of cases of sciatic pain were due to "trouble in the joint." Since then similar statements have now and then been made, and recently the elder Bruce[2] has published a remarkable little book sustaining the thesis that the pathology of sciatica is "trouble in the hip joint." Inferentially he concludes that all sciatica is hip joint trouble. I cannot go so far as he because I am quite sure that occasionally one does see a true neuritis of the sciatic nerve or sacral plexus, and semioccasionally an example of neuralgic sciatica — or at least of sciatica in which the signs of neuritis, except pain, are absent.

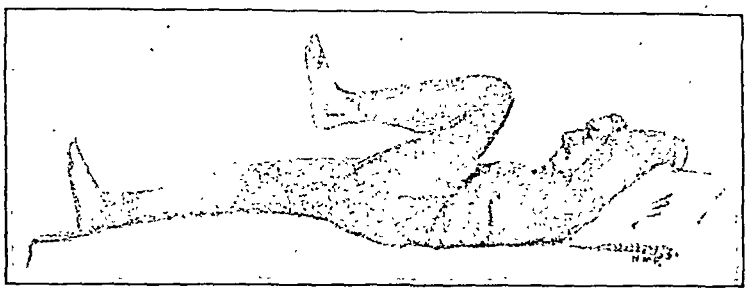

Fig. 7 (Case 2).—Arthritic side; good flexion.

Without touching on the reasons why arthritis leads to a diagnosis of sciatica, I shall simply mention a few signs and symptoms indicating the former and excluding the latter.

Sciatica, like brachial neuritis, causes no limitation of passive motion, with one notable exception — the Lasègue[3] sign — whereas, arthritis of the hip is pretty sure to interfere with some movement or other. Especially is there one sign, so far as I know never present in sciatica, which is of great value in detecting arthritis of lower grades, but which I have not seen described. For convenience of record I call it the *fabere* sign, the letters of the word standing for flexion, abduction, external rotation and extension. With the patient supine on a level surface, the thigh is flexed and then the external malleolus or ankle is placed above the patella of the opposite extended leg. In bad cases even this maneuver cannot be executed without pain, but many patients do it easily. If, however, the knee is now depressed, the ankle maintaining its position above the opposite knee, the patient will complain of pain before the knee reaches the level easily attained in normal persons.[4] This procedure involves flexion, abduction, external rotation and then extension of the thigh, and will catch more cases of arthritis of the hip than any other test with which I am acquainted. Many of the patients have quite free motion of the joint, especially flexion, and in many of them it is not easy to detect any tenderness, though firm pressure with the point of the thumb over some part of the capsule may be much more painful than on the good side. Bruce thinks that the most frequent tender point is at the upper edge of the acetabulum. Heavy percussion of the sole, or the quick shoving of the head of the femur into the acetabulum, which is almost certain to cause pain in tuberculous hip joint disease, generally fails to reveal anything in these nontuberculous cases. But rare indeed is the case which will not be detected by the test described above. In making the test, one must not be deceived by the patient's yielding to depression of the knee by tipping the pelvis. This he instinctively does to avoid pain. The pelvis must remain level.

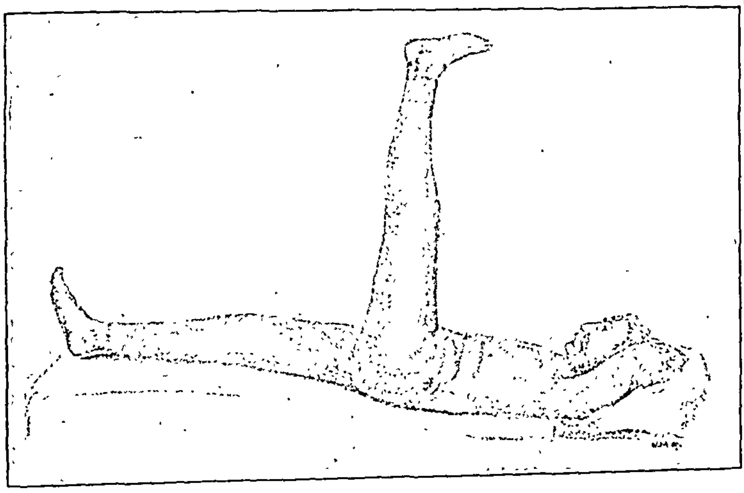

Fig. 8 (Case 2).—Arthritic side; no Lasègue sign.

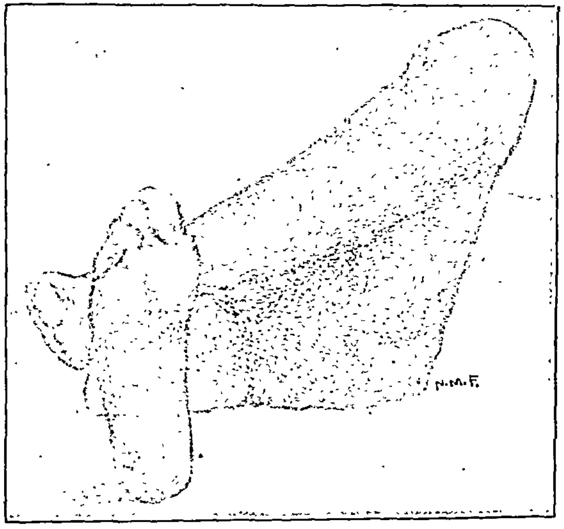

Fig. 9 (Case 2).—Arthritic side; fabere sign; knee cannot be normally depressed.

Figures 1 to 6 illustrate a case in which a woman, aged 50, complained of pain about the left hip and from the hip to the knee (Case 1). She was sent to me by one of the best surgeons in the country with the statement, among others, that a careful examination, including roentgen-ray plates, showed nothing in the hip joint. But the case was one of arthritis of the hip and, incidentally, of the left knee. Figures 7, 8 and 9 are from another case of hip arthritis (Case 2). This patient had not only free and painless flexion of the thigh, but also good abduction and rotation; and yet in this test the knee would go no lower than the point indicated in Figure 9.

It goes without saying that other tests should be used as indicated in the shoulder cases: extension, flexion, abduction, adduction, rotation, strong abduction with rotation, etc., *against resistance.*

---

[1] A number of times I have known the sciatic nerve to be injected or stretched when the trouble was in the joint.

[2] Bruce, William: Sciatica, New York, 1913.

[3] Very similar to Kernig's sign. With the knee well flexed, the thigh can be fully flexed without pain; but when, with the thigh thus flexed, an attempt is made to extend the leg, it cannot be got much beyond a right angle without causing pain.

[4] If the soreness has all gone from the joint and only the relics of a previous arthritis are present, there will be no pain: only inability to bring the knee down to the normal point.

As shoulder arthritis is often accompanied by a like condition of the cervical spine, so hip arthritis frequently is complicated by involvement of the lumbar spine, and probably of the fibrous structures overlying the sacrum.[5] This may cause pain radiating down the extremity, thus assisting in the simulation of sciatica. Bruce believes that the pain down the leg is referred pain, like the pain in the knee of tuberculous hip disease.

If arthritis of the hip is present, naturally we would look for more or less muscular wasting. And this wasting, instead of being an embarrassment in the diagnosis, is an aid. Atrophy due to inflammation of the sciatic nerve of course involves all the muscles supplied by this nerve, no others, and probably the peripheral ones (leg muscles) more. The atrophy of hip arthritis, on the other hand, is found in the muscles that move the joint, especially, as Bruce has insisted, the gluteals. With the patient prone, a distinct flattening of the buttock often is apparent, and with the patient standing, a difference in the gluteal folds.

The other differential criteria distinguishing hip arthritis from sciatica may be taken over bodily from the shoulder cases. In neuritis of the sciatic nerve the Achilles jerk is diminished or lost, whereas in arthritis of the hip it is normal or, more frequently, increased. The knee jerk on the affected side is also nearly always increased. But in arthritis of the spine with considerable involvement of the nerves, these deep reflexes may be diminished.

Bruce[6] says of sciatica, "I have rarely found the tender points of the books." I entirely agree with him. The first reason is that most of the cases are not sciatica. But even in this disease the classical points of Valleix are a delusion and a snare. In arthritis, more or less tenderness on the affected side is almost the rule.

How much of this is of organic origin and how much due to the hypersensitiveness of a long-suffering patient is not always easy to say. I know that in arthritis of the hip, if one firmly punches the gluteal point, the femoral point, the popliteal point and the submalleolar point, frequently one or more of them will be or seem to be tender. But if the examiner is not satisfied with this, and proceeds to punch other places, from the iliac crest to the heel, he will find muscular tenderness, joint tenderness, tendon or fascia tenderness, sometimes even periosteal tenderness, all of which has nothing to do with the sciatic nerve.

Concerning one striking sign or consequence of sciatica, I am in doubt. This is the high degree of scoliosis or lateral curvature sometimes observed. I do not know whether this can be caused by simple arthritis of the hip, but I think that it can.

25 East Washington Street.

---

[5] Cases thought to be lumbago with sciatica or alternation of these two affections are generally cases of arthritis of spine and hip or of the former alone.

TORULA IN MAN

REPORT OF A CASE WITH NECROPSY FINDINGS

PHILIP H. PIERSON, M.D.
SAN FRANCISCO

Torula is a form of yeast, producing lesions preferably in the central nervous system. These lesions macroscopically simulate tuberculosis, from which disease they must be differentiated as well as from lesions formed by coccidioides and blastomycetes. It is not my object in this paper to go deeply into the differential features of these three diseases but briefly to point out the main differences and then present a case of torula infection in a man admitted to the San Francisco Hospital, September, 1916.

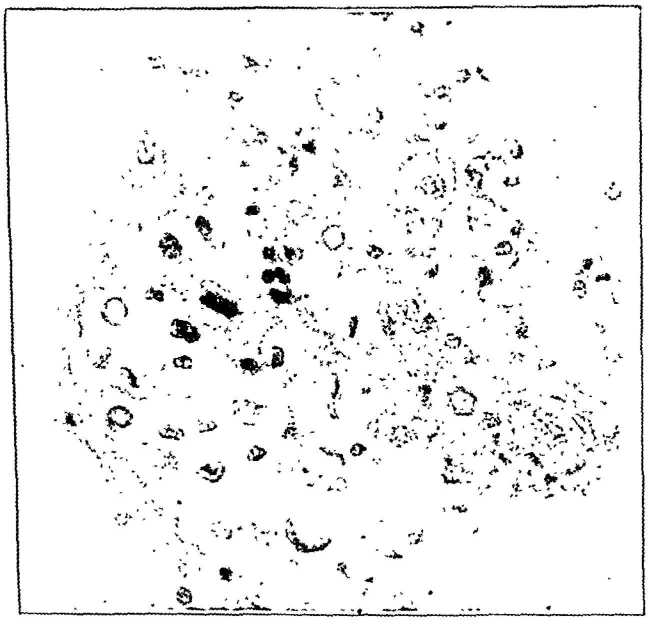

Fig. 1.—Low power view of lesion from cortex, several organisms seen with clear zone of gelatinous material surrounding them.

It is definitely agreed that coccidioidal granuloma and blastomycosis are two different diseases. Coccidioidal granuloma is a disease produced by an organism which sporulates but never buds in tissue. It varies greatly in size, having large forms up to 30 or 40 or even 80 microns in diameter producing many small ascospores which, in turn, escape from the capsule. It simulates tuberculosis in the type of its lesions and in the manner of spreading, principally by the lymphatics and thence to the blood stream. It is largely confined to men in the San Joaquin Valley, California. It is nearly always fatal, as no treatment has been found that is of any benefit.

The organism of blastomycosis varies in size from 3 to 20 microns. It buds but never sporulates, the buds being from one-half to one-third the size of the parent cell. It grows to the size of the parent cell before reproducing itself. It produces nodules with or without caseation, and deep and superficial abscesses with polymorphonuclear leukocytosis. It may affect all organs, including, as a rule, the skin and the bones, and it is helped by iodids. On culture mediums both the blastomycetes and coccidioides grow mycelium sooner or later. The organism of coccidioidal granuloma also produces chlamydospores at the ends of the aerial hyphae in cultures.

Years ago torulae were found to have a marked pathogenic action in animals; but prior to this case there have been only six reported in man—two by Rusk, two by Stoddard and Cutler, and one each by

Türck and von Hansemann. Torula a pseudoyeast, is distinguished from the true yeast by its absence of endospore production under all circumstances, by the fact that it never produces mycelium, that it usually does not ferment sugars, and that it reproduces itself only by budding. It is also more pathogenic for animals than is the true yeast. The central nervous system is particularly susceptible to this organism, which, however, attacks other organs less often. The pathologic changes in the meninges show a chronic inflammatory reaction with areas of caseation like tuberculosis if the lesion is extensive. The organisms, which usually occur in cells, bud in the large vacuoles enclosing them and then, as a rule, destroy the cells. The size varies from 1 to 13 microns. Small organisms may bud, the daughter cell soon attaining the size of its parent. In the older stages the organism develops a resting stage, and there is definite evidence of healing. For this reason, we may believe that the disease, while always chronic, is not always fatal and healing does occur. It is quite possible that many cases exist but are not recognized because of the obscure nature of these healed lesions. The organism possesses a definite cell membrane which stains diffusely and easily with van Gieson's stain, methylene blue and hematoxylin. In the large forms, the protoplasm is not evident. In the medium-sized, it is often shrunken into an irregular shape and takes a diffuse red stain with differential droplets. In the small forms, it fills the organism and has dark staining masses. Around the organism there is always a clear zone composed of gelatinous material. This is one of the characteristic features of the disease, for in coccidioides and blastomycosis there is no such solution of tissue. With or without caseation, nodules are formed composed of epithelioid cells, giant cells (often containing the organism) and lymphoid cells. Caseation occurs centrally, and apparently depends on the action of cell products. There are no collections of polymorphonuclear cells, and no bone or skin lesions. On culture mediums the original growth is most luxuriant on carbohydrate materials such as potato and agar or glucose agar, though scanty on blood serum. After animal inoculation, growth is more vigorous on blood serum, but better on the potato and glucose agar. Cultures continue to be viable even after years of disuse.

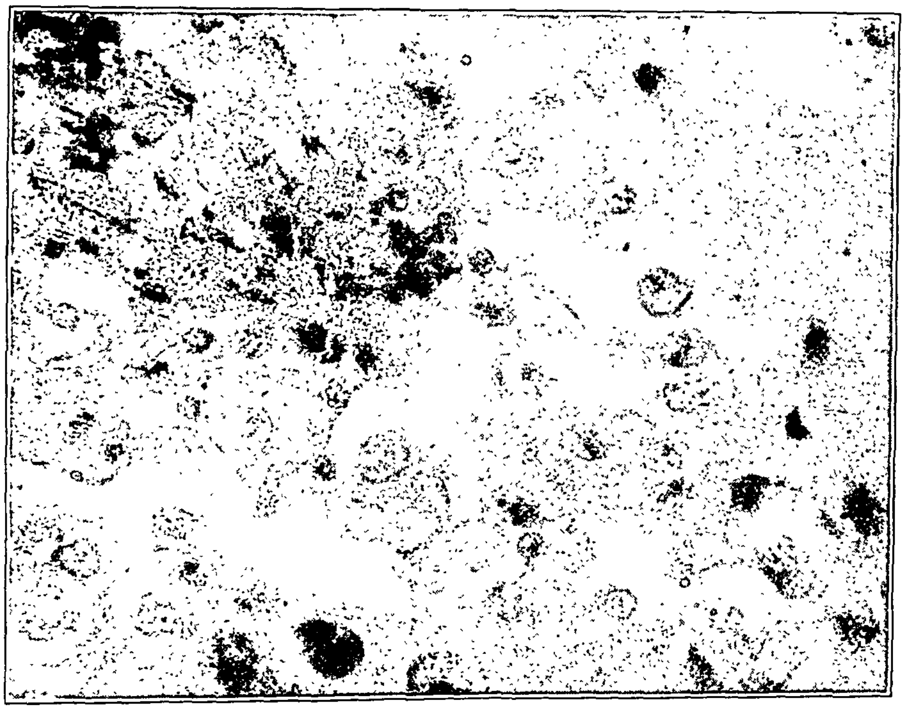

Fig. 2.—Same as Figure 1, under oil immersion. In left lower corner there is a very definite organism. The relative size of large mononuclear and plasma cells *should be noted.*

The localization of lesions in the nervous system is in the meninges, in the perivascular spaces, and in the brain substance by extension from these lesions. They have been found also in the choroid plexus, in the aqueduct of Sylvius, in and about the foramen of Magendie, and in the basal ganglions, the internal capsule, the frontal lobes and the cerebellum. Thus it may be seen that these lesions, although very small, may cause symptoms of grave importance. There is seldom fever or increase of the white count. The optic nerve may become involved, or the choked disk may be secondary to other lesions. Infection probably takes place through the respiratory tract, although it may occur through the pharynx and esophagus. Organisms are taken up by giant and large mononuclear cells, within which they continue to live and multiply, finally destroying them and becoming free. In the brain, organisms are carried along the perivascular spaces, and lesions develop peripherally in the brain substance, chiefly by solution of tissue. This ameba-like action is not as easily performed in other organs, probably because of the greater resistance of their tissue as compared with that of the brain. So we may say that the organism works in two ways: (1) mechanically, in that its growth within cells causes pressure and finally destruction, and (2) chemically, as shown by the solution of tissue. By attacking the host in the central nervous system, the organisms diminish the resistance of the patient even by small lesions critically placed.

It may be said that morphologically torula may be differentiated from coccidioides by its uniform size. It differs also in its method of reproduction, which is by budding rather than by spore formation. It resembles blastomycosis so far as the organism itself is concerned, but differs in its tissue reaction. Blastomycosis has a polymorphonuclear infiltration and no solution of tissue, while torula has this typical lysis of tissue and attracts mononuclears rather than polynuclears.[1]

The report of this case, with the pathologic findings of Dr. Ophüls, follows.

History.—E. F., aged 57, laborer, single, was born in New York, resided in California forty-five years and entered the San Francisco Hospital, September, 1916, with the diagnosis, on admission, of "second degree burn of shoulder, and senile dementia." The family history was negative. The past history was also negative, except for the fact that he had had gonorrhea twice and a soft chancre. While shaving he suddenly and without warning fell to the right, burning his right shoulder on the heater for hot water. He was able to walk, and had no great inconvenience aside from the burn. This was all the history obtainable. The burn healed satisfactorily, and he was transferred to the medical service for an examination of his mental condition. While in the hospital he was quiet, and seldom spoke to any one. At times he tore the dressing off the scalded arm and threw off the bed covers. His appetite was good, and he ate in a sensible fashion. At about the beginning of the third week, he forgot to put on his bath robe when going to the toilet, and seemed distressed when asked why he did this. A few days after the appearance of these symptoms, he developed an inability to grasp objects properly or at the first reach. He would grope past them into the air. When feeding himself, he could not find his mouth easily. This was followed by a tendency to stagger forward when walking, and an inability to articulate properly. October 11, he had to be restrained in bed.

---

[1] A very complete monograph on torula, which may be referred to for further data, is that by Stoddard and Cutler: Torula Infection in Man, Monograph 6, Rockefeller Institute for Medical Research, Jan. 31, 1916.

Physical Examination.—The patient was a large, strong man, restless and irresponsive. Supra-orbital pressure elicited facial response which showed no paralysis of facial muscles. The eye movements were normal. The pupils were dilated with atropin. The tongue protruded in the median line. The heart was not enlarged, showed no murmurs, and was regular in rate, the pulmonic second sound being equal to the aortic second sound. The lungs were negative except for a few râles at the bases. The abdomen was negative, as were its normal reflexes. The extremities were negative. There was a markedly stiff neck and a positive neck sign. The left knee showed a slight jerk not observed in the right. There was no clonus or Babinski. The Kernig was positive. In the examination of the eye, the fundi were normal. The blood pressure was 160.

A lumbar puncture was made, October 17, and 15 c.c. of fluid were withdrawn. The fluid, under considerable pressure, was very yellow, clear and alkaline. The Noguchi and the Nonne reactions were positive. The cell count was 488 per cubic centimeter. The differential showed all lymphocytes. The Wassermann reaction was negative. The culture on the blood serum showed no growth.

October 18, the patient was much clearer mentally, and needed less restraint. His answers were still incoherent. His condition remained about the same. The blood Wassermann was anticomplementary.

October 30, the patient was considerably worse. Examination revealed a stiff neck, and a positive Kernig sign, but no paralysis. As a second lumbar puncture was bloody, no tests were done except a Wassermann, which was negative.

November 1, fundi were negative.

November 2, the patient died, after being incontinent for urine and feces for several days.

The temperature was never more than 97, except on one day when it was 101. The pulse was from 75 to 90, and the respirations were from 20 to 25. On the patient's entrance into the hospital, the white count was 7,600; on the day before death, 15,600. The urine was alkaline, and its specific gravity was 1.020. There was a trace of albumin but none of sugar. Sediment, epithelial cells and bacteria were present.

Pathologic Findings.—A postmortem examination, done at 4:30 p. m., revealed a moderate old cirrhosis of the liver, an old thrombosis of the portal vein, marked ascites, very marked enlargement of the spleen, and numerous old scars in the kidneys, with very marked arteriosclerosis of the branches of the renal artery. There were some old scars in the upper part of the lower lobe of the left lung, and some caseous areas in the peribronchial lymph nodes. There was present also a terminal bronchopneumonia. Examination of the central nervous system revealed a tense dura somewhat thickened. The pia mater on the convexity of the brain was somewhat edematous, and showed markedly diffuse thickening. The convolutions were slightly flattened, and the dura was adherent to the pia near the median line. The large arteries at the base of the brain showed marked thickening and sclerosis. The lateral ventricles contained about 30 c.c. of clear fluid. The choroid plexus was markedly thickened and congested, as was also the ependyma of the third and fourth ventricles. The venous sinuses at the base of the brain were normal. The dura mater of the cord was somewhat thickened, and there was very markedly diffuse congestion and thickening of the pia over the entire cord. On the cut section, the cord showed a decided softening, and bulged over the cut surface. No bacteria were found in the brain or meninges.

Microscopic examination of the brain and cord revealed a marked cellular infiltration and fibrous thickening of the pia. In the pia there were numerous round encapsulated organisms resembling yeasts. Similar organisms were found in groups in the cortex of the brain, where they have caused a liquefaction of the brain tissue without much reaction. A culture taken from the cord was negative.

Microscopic examination of the peribronchial lymph glands showed numerous caseous areas and small cellular tubercles with large giant cells of the Langerhans type. In a few of these giant cells, small encapsulated organisms resembling yeasts were found.

Final Diagnosis.—This was cirrhosis of the liver; thrombosis of the portal vein; chronic splenitis; general arteriosclerosis; arteriosclerotic scars in the kidney; terminal bronchopneumonia, and torula infection of the lungs, peribronchial lymph glands, meninges and brain.

I am indebted to Dr. Ophüls for his help in determining the pathology of these tissues and to Dr. Blaisdell for the photographs.

516 Sutter Street.

THE TOXICITY OF NEODIARSENOL

ERWIN P. ZEISLER, M.D.
Instructor in Dermatology and Syphilology, Northwestern University Medical School
CHICAGO

One of the recent substitutes for neosalvarsan is neodiarsenol, marketed by a Canadian firm. It is claimed to be suitable for intramuscular or intravenous injection in either dilute or concentrated solution. I have employed neodiarsenol in dosages of 0.6 and 0.75 gm. dissolved in from 10 to 15 c.c. of freshly distilled sterile water. The powder is of a somewhat darker yellow color than neosalvarsan, and is not so readily soluble. Even after prolonged shaking there may remain small undissolved particles, which necessitates filtration.

In a recent series of twenty intravenous injections given to fifteen dispensary and private patients in all stages of syphilis, I have noticed an unusually large percentage of reactions. Ten of the patients complained of varying degrees of nausea, vomiting, headache and fever for from twenty-four to forty-eight hours after the injection. One woman with a fresh syphilitic infection (roseola, adenopathy and a positive Wassermann reaction) five days after the administration of 0.6 gm. of neodiarsenol developed fever, headache, vertigo and incessant vomiting which lasted twelve hours. In the absence of any other explanation, I was forced to conclude that this was a late toxic manifestation, possibly an encephalitis. The patient recovered under rest in bed. Another patient in the midst of the injection complained of nausea, faintness and thoracic oppression, with marked flushing of the face. He was immediately given a hypodermic of epinephrin and was able to go home half an hour later. Another patient with symptoms of early tabes collapsed a few minutes after the injection, became extremely pallid, and his pulse became almost imperceptible. The immediate reaction in this case was most alarming, but fortunately he recovered. A very obese patient on account of technical difficulties received 0.6 gm. of neodiarsenol intramuscularly. The pain and local reaction were so intense as to require morphin injections for the next forty-eight hours.

On account of these unpleasant experiences I have abandoned the use of neodiarsenol, and have since then employed the French preparation, novarsenobenzol (Billon), which has given satisfaction.

Clinical Notes, Suggestions, and New Instruments

TRANSFUSION OF IMMUNIZED BLOOD FOR CHRONIC BACTEREMIA: REPORT OF A CASE

Henry P. Wekesser, Ph.G., M.D., Lincoln, Neb.

History.—Miss J., aged 22, a nurse, whose family and early history were negative, developed tonsillitis a few days after having attended a patient whose illness began with acute tonsillitis and terminated in a fatal pneumonia. Cultures from the throats of both the nurse and her patient showed mixed infections, and diphtheria antitoxin was used along with the other treatment.

When the nurse came under my care she had been sick about seven months, during which time one complication had followed another, indicating that never during that time had she been entirely free from the original infection. When the throat infection began to improve, she developed a purulent inflammation in the left antrum of Highmore, which was promptly drained through the nose. Following this infection, all the larger joints of the body became inflamed. During the latter part of the first of several attacks of general arthritis, endocarditis developed. In the treatment of the patient, autogenous and stock vaccines had been used along with drugs and other hygienic measures.

When the patient came under my care, there was still some discharge from the antrum, though the joint invasion had apparently subsided. But the rapid pulse, irregular daily chills followed by fever and sweating, spells of dyspnea with cyanosis, swelling of the ankles, enlargement of the heart, loud systolic murmur at the apex, and a dry hacking cough indicated that the endocardial infection was still active and possibly ulcerative in character. Smears from the antral discharge revealed a predominance of diplococci resembling the pneumococcus. Blood cultures also revealed the same organisms in pure culture.

Rest in bed, drugs, ice over the cardiac region, etc., were ineffective.

Treatment by Transfusion.—Since all other known methods of treatment had been tried, the following plan was devised: A vaccine was prepared from a culture made from the patient's blood. From five to seven doses of this vaccine were administered hypodermically in six-day intervals to four volunteers of about the same age as the patient. Their blood was first thoroughly examined (including the Wassermann test) and tested against that of the patient. In order to immunize them against the patient's infection, the volunteers were vaccinated as needed, and from 250 to 500 c.c. of blood were transmused from an immunized donor to the patient in ten to fourteen-day intervals. More blood was not given at one time because of the cardiac weakness of the patient. In all, six transfusions were made.

Blood cultures were negative after the second transfusion. Chills and fever gradually ceased, and the patient became stronger and was able to leave her bed and even walk a little, two months after the first transfusion.

Although physical signs still indicate an insufficient mitral valve, the patient has again resumed nursing, ten months after the first transfusion.

COMMENT

Whether the endocardial process was simple or ulcerative cannot be proved. The anemia and blood infection disappeared rapidly after the first transfusion. Our present methods of preparing autogenous vaccines make this method safe. Also, it is certainly more rational than the use of vaccines in the treatment of chronic blood infection.

Military Medicine and Surgery

SEXUAL INFECTIONS IN CANTONMENTS AND CAMPS

A FOLLOW-UP SYSTEM FOR THEIR CURE AND CONTROL

JAMES BAYARD CLARK, M.D.
Major, M. R. C., United States Army
NEW YORK

This system, which has been installed in Camp Lee, Va., has three distinct objects in its pursuance:

First, a running record on cards that reflects in outline the entire activity of the genito-urinary service at the base hospital.

Second, a means by which all patients can be observed and their record continued after discharge from the base hospital.

Third, and most important, a method of restriction from any absence from the reservation of all infected patients until on examination such patients are found free from further infectiousness and can safely be allowed a pass to leave the confines of the camp.

The simplicity of this system is best illustrated by the printed forms, which are here shown in the order of their employment.

FORM 1

Genito-Urinary Service, Base Hospital, Camp Lee, Va.
Surname Christian Name Rank Co. Regt.
Diagnosis Duration
Condition on Admission (.. 19..).
Remarks
Condition on Discharge (.. 19..).
To return

Form 1, a card form, is filled in from the ward records of the patient on discharge from the hospital.

If the patient is discharged as cured, the case is considered as complete and the card placed in the permanent filing case. If the patient is not cured, the date and hour for the patient's return for observation is noted on the card, and the card is placed in an envelop, on the upturned flap of which is written the date of return for this patient. The envelop is then placed in a temporary file according to the date, with the flap up, so that from this calendar-like file as the days come round the envelops

FORM 2

Base Hospital, Chief of Genito-Urinary Service, Camp Lee, Va.
From: *Chief of Genito-Urinary Service*
To: Regimental Surgeon ....
Subject: Treatment of patient on discharge from Base Hospital.
1. The following treatment is recommended in the case of
....
Rank Name Rank Co. Regt.
2. It is requested that this man be directed to report to me for
examination,
operation, on .... 19.., at .... M.
treatment,
....
Major, Med. Res. Corps.

are taken out and the cards reveal which patient or patients are to return that day for observation, treatment or operation, as the case may be. When a patient is cured, and the case closed, the card goes back to the permanent file; otherwise it continues running in the calendar file until completed. The subsequent notations when the card is filled are written on a plain card headed by name, rank, etc., and fastened to the original card.

Letter Form 2 is filled out and sent off at the same time the card form is started, that is, when the patient is discharged from the base hospital and returned to the care of his regimental surgeon. This letter form is also used on all subsequent visits to the base hospital by the patient, when it is desirable that he should return.

FORM 3

Base Hospital, Office of Genito-Urinary Service, Camp Lee, Va.

From: Chief of Genito-Urinary Service

To: Commanding Officer, ... Co. .... Regt.

Subject: Failure of patient to report.

1. Your attention is invited to the fact that

....
Name Rank Co. Regt.

has not reported for .... *on* ....

19... .... M., as requested in letter to Regimental Surgeon

.... 19...

....
Major, M. R. C.

Letter Form 3, it need hardly be mentioned, will be but rarely required. Its wording, however, will suggest the moment of its usefulness.

Forms 4, 5 and 6 work rather independently of those just described.

FORM 4

Base Hospital, Office of the Genito-Urinary Service, Camp Lee, Va.

From: Chief of Genito-Urinary Service

To: Regimental Surgeon ....

Subject: Control of infectious cases of venereal disease.

1. The enclosed forms in numerical sequence are for use in cases of venereal diseases under your care, and are self-explanatory.

2. These forms are to be used in all cases of venereal disease, which had occurred *since the opening* of this cantonment, and are to be continued in use in all subsequent cases.

3. These forms will be issued from this office in such numbers as you may require.

....
Major, M. R. C.

These cards with return envelops are sent (a small number of each) to each regimental surgeon, along with the letter of instruction as to their application.

The numbers of the cards and the surgeons they are sent to are first carefully noted in a book kept for that purpose, and all subsequent cards sent out are likewise kept track of, to be checked up, first when the examination is made and finally again when the cards come back.

It has seemed wise to have all patients with sexual infection in camp report to some one center, well equipped with laboratory facilities and specially trained men, and here pass that important final judgment as to whether the patient is free from infectiousness and can with safety be allowed to visit the civil community.

If the civil communities will do as much to protect the soldiers in this respect as the military is doing to protect civil populations, they will do much not only toward shoring up their own social structures, but also toward shortening the war.

A brief study of these cards will make their function and significance plain, both as a check on the infectious soldier, and as a complete record of all such cases in a camp taken from a different angle than are the present military reports.

FORM 5

Camp Lee, Va.

No.......

From Surgeon ....

To Commanding Officer .... Co. .... Regt.

You are hereby informed that ....

is infected with ....

Attention is invited to the C. of O. 1881-1915, Par. 92, subsection 3, page 214, which states that "*while in* the infectious stages the men should be confined strictly to the post."

The above soldier should not be given leave of absence from the reservation until, upon examination, no further evidence of infectiousness can be found, and the *attached* card is signed by surgeon of the Genito-Urinary Service.

This card is to be retained by Company Commander until card of *examination is signed* and returned to him, at which time he is requested to return both cards to the Genito-Urinary Service, Base Hospital.

....

Genito-Urinary Service

No.......

BASE HOSPITAL, CAMP LEE, VA.

Name .... *Rk.* .... *Co.* .... Regt.

shows no further evidence of infectiousness from..................

...., and is discharged from

further treatment.

....Major, M. R. C.

Base Hospital..............19 , ...

Before any leave of absence can be obtained following above exami*nation, this card is to be taken by the soldier to his Company Com*mander.

It has been mentioned that the latter set of forms works rather independently of the former, and this is necessarily so, as a large proportion of sexually infected soldiers are cared for by their regimental surgeons and do not come to the base hospital at all; however, this plan of having every man come to one central bureau for his final examination is of much importance, as it not only brings the regimental surgeon and the base hospital surgeon into a closer and more purposeful cooperation in reaching a higher standard, but also increases the respect of the soldier in the vitally important subject of a sexually clean bill of health.

ENVELOP FORM 6

War Department Penalty for Private Use $300.

From Commanding Officer

Co. Regt.

....

Official Business.

For return of card No. *XXX*

To Chief of Genito-Urinary Service,
Base Hospital,
Camp Lee, Va.

If what many are seeking to make us believe today is so, that there is more loss of service in the armies of our allies through sexual infections than through the usual wounds of war, then to the Medical Corps of our Army there comes a warning not to be lightly laid aside, and to the medical officer whose duty includes the care and control of sexual sickness there comes a singular responsibility, for in the manner of his doing, it may be that the balance of man power in the final struggle of this war shall be determined.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Subscription price . . . . . Five dollars per annum in advance

Contributors, subscribers and readers will find important information on the second advertising page following the reading matter

SATURDAY, DECEMBER 29, 1917

THANK YOU

In response to the note in last week's issue of The Journal, a large number of remittances for Fellowship dues and subscriptions for the ensuing year have been received. No doubt at this time many are at the point of remitting. For the convenience of those who may have misplaced the slip enclosed in last week's issue, another is inserted in this number. Those who have already remitted will of course ignore the slip in this issue.

RECENT WORK ON GASEOUS GANGRENE

Recent investigations have added greatly to our knowledge of gaseous gangrene. To determine whether the conditions currently designated as gaseous gangrene are associated with the same or with different bacteria, Weinberg and Seguin[1] made an exhaustive bacteriologic study of ninety-one cases of gangrene. They found anaerobic bacteria in the wound in every case, occasionally just a single anaerobic species, occasionally several anaerobes in association; but in the majority of the cases several different anaerobes and aerobes were present. This result might be taken to indicate that no one bacterium plays a predominant rôle in the development of gaseous gangrene, and consequently that the outlook for a specific treatment based on a definite and constant etiology is not promising. It is highly significant, however, that the most common anaerobe by far in this series, being present in two thirds of the cases, was *Bacillus welchii,* also called the gas bacillus, or *B. perfringens,* as the French call it. Next in frequency came a bacillus which is called *Bacillus oedematiens,* and then the *vibrion septique* of Pasteur, or the bacillus of malignant edema. Probably these two organisms are closely related. In the cases with abundant gas production, extensive crepitation, bronzing of the skin, etc., that is, the classical form of gaseous gangrene, *B. welchii* was the dominating organism, while *B. oedematiens* (bacillus of madignant edema) predominated in certain toxic cases with progressive edema; but cases of mixed infection with both these bacilli were observed also. The investigations of Weinberg and Seguin emphasize, consequently, that in gaseous gangrene, that serious complication of war wounds, *B. welchii* is by far the most important organism. Injured muscle, exposure of bone marrow and interference with the circulation on account of arterial injury, tight splints and casts are conditions that favor the growth of this bacillus, infection with which is bound to occur with great frequency because it is in the soil and on the skin and clothes of the soldiers, especially those in the trenches. Laying wounds open and cleansing them thoroughly, removing all foreign materials and damaged tissue, naturally will cut short many cases; while in many others the invasion of the bacilli and the resulting general intoxication rapidly pass beyond arrest and cure even by the most skilful and thorough local treatment, and demand new and more subtle methods.

Probably the decisive step toward finding one such method already has been taken. Weinberg and Seguin[1] urge the use of antitoxic serums which they have prepared against the three most important anaerobes concerned in gaseous gangrene, but we as yet know practically nothing of principles and methods they have followed in developing these serums. In earlier communications, Weinberg[2] states that antitoxic serums have been secured from the horse against *B. oedematiens* and *vibrion septique,* and antibacterial serum against *B. welchii* (*B. perfringens*); but no exact description of the methods used is given. In the meantime, Bull and Pritchett,[3] whose work has been discussed in these columns before, laid a sound experimental basis for antitoxic serum treatment of infections with *B. welchii* by showing that when this bacillus is grown in broth with sterile rabbit muscle a typical toxin is produced, which in the guinea-pig causes symptoms typical of the infection, and which in suitable animals evokes the elaboration of a specific antitoxin with both protective and curative properties under experimental conditions. The discovery that *B. welchii* produces a true toxin places it in the same group as *B. diphtheriae, B. tetani* and *B. botulinus.* DeKruif, Adams and Ireland,[4] as well as Bull,[5] find that the toxin produced by various strains of *B. welchii* is neutralized by the same antitoxin, which would indicate that if the natural infection can be influenced by antitoxic serum, one and the same toxin may serve as the antigen in the process of immunization. DeKruif and Bollman[6] further show that acid plays no part in the intoxication produced by *B. welchii,* as asserted by earlier workers, and thus support the view of Bull and Pritchett, that a true toxin is the essential factor in the general intoxication.

[6] DeKruif and Bollman: Jour. Infect. Dis., 1917, **21**, 588.

From the foregoing it appears that *B. welchii* is a toxicogenic bacterium, and that it is the most important bacterium concerned in so-called gaseous gangrene; that other anaerobic bacteria, the mechanism of the infection with which we do not understand as well, may also be concerned, and that the stage is now set for the treatment of gaseous gangrene with antitoxic serum. The outcome will be watched with much interest.

THE CEREBROSIDS OF THE BODY

Only a few years have passed since the so-called lipoids were regarded as essentially characteristic of nervous tissue, from which some of them were first prepared in amounts adequate for careful study. Subsequent investigation demonstrated a far more widespread distribution of these fatlike organic substances in tissue of the most diverse sort, in both the animal and the plant kingdoms. The lipoids, or at least representatives of this somewhat heterogeneous group of compounds, are today looked on as important constituents of living cells in general; and they appear to play a prominent part in the structure and function of the cell membranes. Their physical properties are quite unlike that of the ordinary water-soluble components of tissues; and the unique character of their chemical composition suggests important functions of a chemical nature, whatever they may be.

Among the lipoids the phosphatids, a group including lecithin and kephalin, have received the most attention. The assumed and possible relations of these substances to various physiologic and pathologic phenomena have frequently been discussed in THE JOURNAL. Only recently kephalin has come into unanticipated prominence, owing to its presumable rôle in the reaction of blood coagulation.[1] Lecithin is being brought into relation to the metabolism of the fats, especially through the researches of Bloor. Cholesterol, long familiar as a conspicuous constituent of the brain and a component of gallstones, likewise has acquired a new prominence in connection with the blood. Less well known is that group of lipoids to which the designation of cerebrosids has been given. The pioneer worker on this type of substances was Thudichum,[2] who assumed the existence in brain tissue of at least two different compounds characterized by yielding, on decomposition, the sugar galactose together with a nitrogenous base, sphingosin, and a higher fatty acid.

Thus the names of two cerebrosids, phrenosin and cerasin, entered the literature of physiologic chemistry in connection with the study of the composition of the brain. Phrenosin yields cerebronic acid, whereas, from cerasin, lignoceric acid has been obtained. Not only have the cerebrosids now been found in other organs than the nervous system, but there appears to be an identity of these lipoid substances in the several tissues, just as has been found true of other lipoids. Levene and West[3] have lately demonstrated that the cerebrosids in egg yolk, the liver and the kidney seem to be identical with those obtained from the nerve tissue. They yield the same sugar, galactose, the same base, sphingosin, and the same fatty acids, lignoceric and cerebronic. It is not certain whether the two cerebrosids, phrenosin and cerasin, occur in the same proportions in nerve tissue and in the various other organs. This uncertainty applies, however, to every other individual lipoid. It is quite possible, as Levene and West remind us, that the proportions of the lipoids vary with the variation of the organ. Certainly it represents a distinct step in advance to have more intimate knowledge of the chemical compounds with which the performances of our body cells are inevitably concerned. Metabolism, immunity, heredity are merely words that express in an as yet indefinable way the chemical manifestations bound up with the performance of compounds at present unidentified — possibly the very substances that these newer lipoid researches have helped to elucidate. Studies in this field are attended with enormous difficulty; they should be encouraged all the more because of the great promise which the successful invasion into its secrets holds out.

URIC ACID AND GOUT

It would be impolitic and essentially wrong, Otto von Fürth[4] wrote a few years ago in relation to gout, simply to ignore whatever judicious objective observers have found appropriate after decades of study, merely because no theoretical explanation has been found. It should never be forgotten that the observations of the practitioner may be true and the theories may be false, and that a judicious natural scientist generally values the former more than he does the latter. Unfortunately, objective observation, especially in the treatment of chronic internal affections, is endless and difficult; and for that very reason this has been and will be at all times and among all people the favorite field for both scientific and unscientific charlatanry.

Assuredly, therefore, we need to secure the attainable scientific facts regarding gout, and particularly its much discussed relation to uric acid, with which it has been prominently associated ever since Garrod's studies in 1848. Garrod's contention, that the bloody of gouty persons is characteristically richer in uric acid than is the circulating medium of normal persons, long ago awakened inquiry as to the cause of this phenomenon. The accuracy of the observations might well have been debated up to a few years ago, when microchemical methods of analysis greatly simplified the determination of the facts with comparative ease on a larger number of patients. At present it seems to be agreed that the gouty show an increase of uric acid in the blood. The latest report[5] in this field, reviewing the situation, concludes that on statistical evidence more than 3 mg. of uric acid per hundred c.c. of blood, with the patient on a purin-free diet, is a symptom of gout, but is not a diagnostic sign of the disease.

---

[3] Levene, P. A., and West, C. J.: Cerebrosides, V, Cerebrosides of the Kidney, Liver, and Egg Yolk, Jour. Biol. Chem., 1917, **31**, 649.

[4] Von Fürth, Otto: Chemistry of Metabolism, translated by A. J. Smith, Philadelphia, 1916, p. 193.

Is this increase of uric acid in the blood of gouty patients to be ascribed to either an increased entrance or a diminished escape of the material? At present there is little reason for postulating an increased genesis of uric acid in gout, although such a theory was popular a few years ago. There can be no question, however, of occasional delayed excretion of uric acid by the gouty. It was quite natural, therefore, to correlate the uric acid stagnation with defective renal function. When no clear indications were discernible, a "latent" nephritis was sometimes postulated in explanation of the "gouty diathesis." Today the possibility of applying functional tests to the kidney makes a vague explanation of this sort scarcely justifiable. It is not easy to distinguish cause and effect in the alleged association of gout and nephritis. In their investigations at the Peter Bent Brigham Hospital in Boston, McClure and Pratt have become convinced, like others before them, that although in the majority of gouty patients there are increased amounts of uric acid in the blood, a large percentage do not have markedly increased quantities of other nonprotein nitrogenous substances in their blood when on a purin-free diet. Indeed, they categorically state that a marked retention of nonprotein nitrogen is not frequent in gout.

It was to be expected that considerable light might be thrown on the meaning of the augmented uric acid in the blood if the fate of exogenous purin-yielding foods in gouty subjects could be ascertained. Human patients alone suffice for this purpose, since, in the common laboratory animals, in contrast with man, uric acid is further oxidized in the body. McClure and Pratt have followed the effects of injections of uric acid, and of the ingestion of purin-forming products, in man. Their results, along with previously known facts, indicate that in normal and nongouty as well as in gouty persons there is great variability in the quantity and in the duration of exogenous uric acid excretion. For this reason, they say, a diminished or a protracted exogenous uric acid output most probably results from factors other than disturbances in the purin intermediary metabolism. If this is not true, then derangements in purin metabolism are so common that their importance in the etiology of any diseased condition is problematic.

If the failure to eliminate exogenous uric acid promptly is not peculiar to gout, though it would appear to occur more frequently in gouty than in nongouty persons, we may assume, with the Boston investigators, that the acid enters the body tissues in some way, since it is not known to be destroyed in the body. For the moment, in attempting to make a diagnosis it is perhaps preferable to depend on the analysis of the blood rather than on the failure to excrete exogenous uric acid promptly.

CREATINURIA

The excretion of creatin in the urine is a phenomenon now generally recognized to occur at times in normal persons. The intake of a very large quantity of creatin may lead to some elimination of this compound; but creatinuria occurs in healthy persons under conditions that are not referable to such a cause. Normal men do not excrete creatin through the kidneys under usual conditions of diet. Normal children, however, are now recognized to excrete creatin commonly during the period of adolescence. This was demonstrated in this country several years ago by W. C. Rose[1] at Yale University and verified by Folin and Denis[2] at the Harvard Medical School. Subsequently Krause[3] showed that the younger the child, the less its ability to retain creatin administered by the mouth. These observations have been puzzling to the physiologist and have led to a variety of hypotheses as to the unexpectedly unlike behavior of the juvenile and the adult organism, respectively, in the matter of spontaneous creatinuria. The problem was seemingly further complicated by the statement of Krause[4] that the urine of normal women frequently contains small amounts of creatin. This creatinuria, according to Krause, is associated with the sexual cycle, and is always present after menstruation; and while in some individuals it may disappear during the intermenstrual period, in others it persists.

The facts regarding creatinuria in children remain unchallenged. With respect to the possibility in women, Mary S. Rose[5] has reinvestigated the subject quite extensively over longer periods of time on a number of adult women. She reports that the creatin output of women is very irregular, and no definite relationship between creatin and creatinin has been demonstrated. There is no clearly defined connection between the creatin output and the sexual cycle. Creatin tends to disappear at the onset of menstruation and to reappear shortly afterward, but it may do the same at other times also.

[5] Rose, Mary S.: Creatinuria in Women, Jour. Biol. Chem., 1917, **32**, 1.

In previous issues of The Journal we have discussed the current hypotheses regarding creatin and creatinin excretion. The theories that creatinuria is an accompaniment of inadequate carbohydrate metabolism induced either by dietary deficiencies or by disease, or that it is a consequence of a condition of acidosis, have been found inadequate to explain all cases in which creatin is excreted. More recently the reference of creatin elimination to a high level of protein metabolism has been revived as a working hypothesis. Thus Denis[6] found that forced protein feeding induces creatinuria in certain cases of hyperthyroidism, whereas a low protein diet produces a creatin-free urine. She has reported similar results also from varying the protein intake of children.

Denis and Minot[7] found it possible, in experiments on two normal women, to cause creatin excretion by feeding a high protein (creatin-free) diet, and to cause the creatinuria so produced to disappear by the consumption of a low protein diet. In two men to whom a similar experimental procedure was applied, Denis and Minot were unable to produce creatin excretion even when a sufficient amount of protein was consumed to cause the urinary nitrogen to rise to 34.5 gm. per day.

This contrast in the apparent behavior of normal men and women toward the same diets, with respect to the creatin output, argues for some distinct difference in their metabolic capacities. There are, however, apparent conflicts in the data available. In her observations on women, Rose[5] found not only that creatin is excreted on diets liberal in carbohydrate and causing no acidosis, but also that the excretion is not definitely influenced by the amount of protein in the diet. She therefore inclines to the view, to quote her own words, that creatin is constantly being formed in relatively large amounts and is normally for the most part either utilized or destroyed; that the adult man can metabolize considerable amounts, while the child's powers are much weaker, so that creatin in the latter represents a balance between formation and destruction; and that women occupy a position intermediate between men and children, being able to metabolize most if not all of the creatin that they may produce, the amount fluctuating with perhaps a variety of conditions. Without venturing any more detailed hypothesis, Denis and Minot repeat the suggestion that the ease with which creatinuria can be induced in normal women may be due to their relative lack of muscular development as compared with that of man. No explanation yet offered will permit a satisfactory interpretation of the now available facts; but the way to an understanding is unquestionably being made more easy by the increasing number of observations under well controlled conditions of diet.

Current Comment

EXPLOITING CHICAGO'S FOREIGN BORN

Four years ago the Chicago *Tribune* published a series of articles dealing with practically every advertising quack in the city of Chicago. In preparing the series it assigned to some of its reporters the task of investigating the local quack industry, and the reporters performed their tasks well. As a result of the light turned on this business, those English-language newspapers of Chicago that had heretofore offered a welcome haven to the quacks threw out this entire line of advertising—and kept it out. Quackery, however, was not dead in Chicago. One by one the fakers came back and adapted themselves, as quacks will, to the changed conditions. Chicago has a tremendously large foreign population, and is publication headquarters for a great many foreign-language newspapers. These the quacks patronized—and the papers have, apparently, been willing accomplices. Now the *Tribune* is publishing a second series of articles on the quacks. As in the previous campaign, a reporter has been paying visits to the various quacks, this time in the rôle of a foreign-born citizen. History is repeating itself. It remains to be seen whether the foreign-language press of Chicago can be shamed into the same action that some English-language newspapers took four years ago. If they can, the more blatant quacks of Chicago will have received a body blow, for only with the connivance of newspapers can these scoundrels ply their trade. The foreign-language press of the country professes to stand as champion of the foreign-born Americans. If this attitude is not a pretense, their course in the present matter is clear.

ULTRAVIOLET LIGHT AND BACTERIA

To understand something of the action of ultraviolet light in contrast with ordinary spectral light in relation to living structures, it must be borne in mind that the greater number of the constituents of living cells are colorless, that is, they do not absorb rays of the wave length of visible light. As many of them absorb ultraviolet light, however, the possibility of effects on living cells is thereby afforded. Sunburn (erythema solare) is a familiar illustration of inflammation due to the effect of ultraviolet light on the skin. Severe conjunctivitis also is caused by this agency, unless the eyes are protected by spectacles that are impermeable to the short waves. This danger is appreciated in electric welding, in which the arc spectrum of iron sends out the ultraviolet rays. The effects of this form of light do not extend far into more complex organisms because the absorbing power of protoplasm for ultraviolet rays is very considerable. When a better opportunity for penetration is given, as in small organisms like bacteria, a destructive effect is readily manifested. Hertel showed this in 1905; and subsequently Henri and his co-workers in Paris extended our knowledge of what has been called the abiotic action of ultraviolet light. Usually the microorganisms have been exposed in the presence of nutrient culture mediums in order that the destructive effects might be studied. These evidently offer considerable protection against ultraviolet rays.[1] At the Henry Phipps Institute of the University of Pennsylvania, Newcomer[2] has recently found that when the micro-organisms are suspended in water the baneful effect of the rays is far more obvious. Exposures to iron, zinc and copper sparks were tested. The killing power of ultraviolet light, in the case of typhoid bacilli studied by Newcomer, begins to decrease at about 2,800 Ångström units; and in the spectral region where the sun's rays begin, the sensitivity is practically nil. Typhoid bacilli unprotected by absorbent mediums are about one two-hundredth as sensitive to ultraviolet light of wave lengths from 2,100 to 2,800 Ångström units as is the photographic plate.

CHANGES IN THE PURGED INTESTINE

The postoperative lethargy of the bowel, the nausea and the apparent inertia of intestinal movement following a laparotomy form a picture familiar to every clinician. This sluggishness with its attendant gas pains, vomiting, etc., is one of the prominent symptoms of distress that usually persists for a time after operations, and challenges the efforts of the physician directed toward its relief. As a preliminary to operative procedures, it is a widespread custom to prepare the patient by purging. The staff of the George Williams Hooper Foundation for Medical Research at the University of California Medical School has made a direct test of the physiologic effect of purgation on the condition of the bowel[3]. It seemed reasonable to suppose, they state, that if purgatives have either a tonic or a depressant effect on the intestine, these effects should be demonstrable in excised segments beating in a suitable medium. Furthermore, if the treatment with purgatives should happen to leave some region of the intestine more fatigued or more irritable than others, the orderly progress of peristaltic phenomena might be interrupted. Alvarez and Taylor, who conducted the experiments on animals, thus state their findings:

> The well purged rabbit is likely to be apathetic and to look sick. Its bowel is full of gas and fluid, and the mesenteric circulation is disturbed. Excised segments beat poorly and irregularly in Locke's solution, and they fatigue quickly. They respond poorly to drugs. Some parts of the bowel are abnormally irritable, while others fail to respond at all to powerful stimuli. This unevenness in the gradient of muscular forces must interfere with the steady progress of food through the gut; and it probably favors the production of colic and gas pains.

Calomel and cascara did not seem to poison or fatigue the segments of the intestine, as did castor oil, magnesium sulphate and jalap. The investigators conclude on the basis of their experimentation with animals that it is not wise to purge shortly before an operation in which the bowel must stand drying, handling, cutting and sewing. The surgeon may well give some heed to this suggestion, at any rate to the extent of carefully weighing the reputed advantages of preoperative purgation against the detriment suggested by these studies.

PHENOLSULPHONEPHTHALEIN IN DIAGNOSIS OF DISEASE OF THE CENTRAL NERVOUS SYSTEM

Until quite recently, the textbooks have been singularly reticent about the functions of the cerebrospinal fluid. It has long been known that there may be an exchange of constituents between the cerebral sinuses and the blood stream; but the paths of transference have been a subject of some uncertainty. The debate has in part hinged about the question as to whether the spinal fluid is merely a sort of lymph bathing the nervous tissues and directly communicating with the rest of the lymphatic system, or whether it represents a secretion of special character and different origin. In any event, it is well understood that foreign water-soluble substances introduced into the cerebrospinal fluid find their way into the general circulation, from which they can subsequently be excreted by the kidneys. Thus Dandy and Blackfan[1] showed that phenolsulphonephthalein, which has been used widely as a test of renal function, is harmless when injected into the subarachnoid space, and appears in the urine in normal infants in from four to ten minutes. They employed the test pigment in a study of hydrocephalus. It has more recently been employed by Mehrtens and West[2] at the Leland Stanford Junior University School of Medicine, to determine, if possible, whether there might be some disturbance in the excretion of phenolsulphonephthalein in diseases of the central nervous system other than hydrocephalus. One naturally thinks in this connection of disease characterized by meningeal inflammation. Thickening and edema are common involvements of the vascular system and membranes of the nervous system. The California investigators have found that phenolsulphonephthalein injected into the subarachnoid space in normal persons appears in the urine in ten minutes or less. Diseases of the central nervous system, especially when involving the meninges, produce a lengthening of the appearance time to as much as seventy minutes in some cases. This delay cannot be accounted for by disease of the kidneys, or by the reduction of the phenolsulphonephthalein in the spinal fluid. In syphilis a lengthening of the appearance time may be produced before any other evidence of central nervous system involvement has appeared. An example is afforded by clinical tabetics, who furnish meager pathologic findings through examination of the spinal fluid, yet may exhibit a great delay in the excretion of the dye. Admitting that advanced general arteriosclerosis may be a factor in causing the delay in some instances, the method indicated is nevertheless of considerable significance in a diagnostic way because it may facilitate detection of organic disease when the ordinary spinal fluid findings are negative or incomplete.

Medical Mobilization and the War

NAVAL DENTAL RESERVE FORCE FULL

The Surgeon-General of the Navy announces that the Navy's needs, so far as dentists in the Naval Reserve force are concerned, are more than satisfied, and that no applications are receiving favorable consideration at present.

RED CROSS COMMISSION ON WAY TO ITALY

The permanent Red Cross Commission for Italy, which is to take over the relief work begun by Major Murphy, has sailed for that country. Robert P. Perkins, New York, is in charge of the commission, and Dr. Joseph Collins, New York, is one of the members. Major Murphy has cabled that it has been necessary to place contracts which have practically used up the $250,000 which the Red Cross appropriated for relief work in Italy, and has requested an additional $250,000. He states that there is a great deal of work to be done, as the German successes in Italy involved the destruction of many military hospitals.

COMMITTEE VISITS ITALY

On the recommendation of Surgeon-General Bradley, General Pershing appointed a committee to study hospital conditions, surgical treatment and sanitary medicine in Italy. The committee consisted of the following members: Majors Angus McLean, George E. McKean and Harry N. Torrey. Lieut. Bror H. Larsson accompanied the expedition as secretary, and Capt. James W. Inches represented the American Red Cross. Permission for this investigation was obtained through the Italian military authorities, and was granted for fourteen days.

NEWS OF THE CANTONMENTS

Thirty-Fourth Division, Camp Cody, Deming, N. M.

Dec. 21, 1917.

RED CROSS

This organization was authorized by Act of Congress in January, 1905, to be a "medium of communication between the people of the United States and their Army. . . . No volunteer aid from any society or association will therefore be accepted for the Army of the United States except through the American National Red Cross."

An office and store room has been established at each of the large camps for the purpose of adding in any possible way to the comfort and happiness of the men, and of helping with supplies prepared in advance for any emergency that may arise. If needed, these supplies are given freely through the division surgeon without any charge, request being made by the Red Cross merely for a receipt, which can be used as a voucher in connection with the return of property made by the local representative. Such donations are made for enlisted men only, officers being able to provide for themselves. But the War Department has looked so carefully after the needs of soldiers that thus far its forethought has prevented any considerable requirement on the Red Cross, whose watchful representative has usually been able to find very few needs left uncared for.

Mr. Edwin H. Brown of Minneapolis is the representative at Camp Cody, and like all other field directors his services are given without salary or remuneration from any source. No agent of the Red Cross at this camp is in receipt of any salary. Through this office there have been received to date and for the most part distributed 4,785 woolen sweaters; 4,705 woolen wristlets; 2,304 woolen mufflers; 2,598 woolen socks; 43 woolen helmets; 1,000 goggles; a Pathé phonograph to the base hospital; 65 clinical thermometers, and an electric heater to the base hospital.

At this season a particularly grateful function of this "medium of communication between the people of the United States and their Army" is the distribution of Christmas packets. Enough have come from the homes of America to provide one for each man, carrying not only its own cheer into the camp Christmas, but also the home love and ideals, which are the foundation of American character and strength.

SCHOOLS, MEDICAL DEPARTMENT

Four of these are now in operation. 1. The school for medical officers. The program for December follows:

SCHOOL FOR MEDICAL OFFICERS, 34TH DIVISION

Dec.	2 p. m.	3 p. m.	7 p. m.	8 p. m.
3	....	....	Examination	Examination
4	Examination	Examination		
5	....	....	Examination	Work of the Med. Dept. in France, Lieutenant Ramel, French Army
6	Field problem, directed by Captain Milne	Field problem, directed by Captain Milne		
7	Field hospital, internal organization, Major Knott	Care of animals, Lieut.-Colonel McGee, 135th Infantry		
10	....	....	Work of the M.D. on the West front, Captain Landale, British Army	Tactical use of infantry, Colonel Mollison, 136th Infantry
11	Field hospitals, their equipment and use, Major Knott			
12	....	....	Tactical use of field artillery, Major Oakes, 59th Artillery Brigade	Tactical use of Engineer corps, Colonel Schulz, 109th Engineers
13	Field problem, directed by Captain Milne			
14	Shell shock, Captain Phillips	Work of ophthalmologist in the Army, Captain Covington		
17	....	....	Desiderata in treatment, regimental aid station, Major Prudden	Desiderata in treatment at dressing station, Lieutenant Stolz
18	Desiderata in treatment at field hospital, Captain Milne	Desiderata in treatment at base hospital, Major Davis		
19	....	....	Tuberculosis: diagnosis and treatment, Major Bullock	Pneumonia in the Army, Captain Duncan
20	Field problem, directed by Captain Milne			
21	Meningitis, Lieutenant D'Alton	Tonsillitis and rheumatism, Major Bigelow		
26	....	....	Gas defense, Lieutenant Hickok	Burns, Major Thomas
27	....	....	Recent advances in military hygiene, Major Fagan	Cardiovascular disease in Army, Captain Carter
28	Field problem, directed by Captain Milne			
31	Cardiovascular disease in the Army, continued, Captain Carter	Exanthems, Major Pederson		

2. The school for officers of the Dental Corps meets for two hours, five days weekly. Lieut. Mortimer Sanderson, D. C., U. S. Army, is supervising dental surgeon of the division, and Lieut. J. J. Ogden, D. R. C., from Memphis, Tenn., is assistant dental surgeon. Thirty officers of the Dental Reserve Corps constitute the staff, and work in the base hospital and in the infirmaries of the various regiments constituting the division.

3. The school for noncommissioned officers of the Medical Department is just concluding a six weeks' course, which will be continued by the medical officers of each of the various organizations.

4. The school for gas defense. This is conducted by Lieut. Asa L. Hickok, M. R. C., from Meshoppen, Pa., and Lieut. C. N. Austin, S. C., Oak Park, Ill.

A gas house has been established, gas masks are provided, and arrangements are made so that every one in the division will learn the measures of defense necessary to meet this German method of making war.

Eighty-Fourth Division, Camp Zachary Taylor, Louisville, Ky.

Dec. 24, 1917.

CHRISTMAS

Christmas and New Years furloughs at Camp Zachary Taylor did not total more than 2,500 men. Much disappointment was felt when it was announced that only 5 per cent. of the command could be furloughed. Many of the Louisville soldiers found it impossible to get leave to visit their homes on Christmas day. But they found much of good cheer at the camp. The sympathetic public gave liberally toward the Christmas celebration and every man was remembered. Comfort bags, sweaters, socks, tobacco, and many acceptable gifts of all descriptions were given the men.

Among the organizations which have been prominent in arranging for Christmas celebration at the camp are the Camp Service Committee of the Red Cross and the Louisville Committee of National League for Women's Service. These organizations particularly took care of seventeen noncontagious wards at the base hospital in which 950 Christmas presents were distributed.

ADDRESSES

Col. John H. Allen, December 19, addressed the regular December meeting of the Jefferson County Dental Society. Colonel Allen has been very active in having the division equipped with proper dental apparatus, and an ample number of men for taking care of the mouths of every one.

CENSORSHIP

Brigade-General Carleton has placed a ban on indiscriminate writing in the camp. Officers and men may write for publications but their products must be censored by the division intelligence officer. Society editors of papers have been asked not to use their social columns for announcing the departure of officers from the camp or from their homes to other training stations. Only that news which is thought desirable by the division intelligence officer will be given to the press; all other general information is to be withheld.

FOOD CONSERVATION

Use of sugar and lard has been limited at the camp. Organization commanders have been instructed to have coffee prepared in their organizations sweetened before serving to the men, and they will use a maximum of 7 ounces of sugar to each gallon of coffee. In baking not more than 1 pound of sugar and 1 pound of lard will be used with each 100 pounds of flour.

HEALTH OF THE COMMAND

To controvert the false rumors which have been going the rounds regarding the health of the troops, the official records show that since the base hospital was established at the camp 3,684 patients have been treated, and only twenty-eight deaths have occurred, two of which were suicides. Weekly reports from the office of the Surgeon-General at Washington prove that the mortality list and sickness of this command is less than those of other cantonments and camps in the country. From the press, relatives and friends of the soldiers have been warned not to place any credence in the malicious rumors that are being spread, and to assist the government authorities in apprehending those circulating them by reporting the identity of such persons.

Capt. P. J. Stewart, M. R. C., of Paducah, Ky., in charge of the surgical wards at the base hospital, has just been promoted to the rank of major.

It is reported that upward of 3,000 enlisted men from Jefferson and Columbus barracks will be sent to the Lincoln Division before January 1. These men enlisted before December 15, the last day of enlistment according to the last ruling of the provost-general. Fourteen thousand men are included in the outstanding 35 per cent. No definite word has been received as yet regarding their coming. The present strength of the camp is 25,000 men, with accommodations for 44,000 men.

Surgeon-General Gorgas has been expected at Camp Zachary Taylor for the past two weeks. Quite a stir was caused at the base hospital when a telephone call was received for Miss Gallagher, the head nurse, during her temporary absence from the camp. When asked who was talking the reply came back, "General Gorgas."

The Three Hundred and Thirty-Sixth Infantry (composed of Louisville men) and the Three Hundred and Thirty-Fifth Infantry (composed of southern Indiana men) have at last been released from measles quarantine.

ARMY AMBULANCE WORK

All Louisville was shocked to learn of the terrible Louisville and Nashville Railroad wreck, December 20, but thrilled over the prompt assistance rendered the wounded by the ambulance companies from Camp Zachary Taylor. Forty-seven people were killed and as many injured.

Col. John H. Allen, division surgeon, was lecturing before the Louisville Dental Society when he learned of the accident. He immediately communicated with the commanding general of the camp, who gave permission that the ambulance companies be ordered to the scene. At 10:10 p. m., Colonel Allen communicated the order to Major Fletcher, commanding officer of the ambulance companies, to at once report to SS. Mary and Elizabeth Hospital, with its complete medical equipment, including twelve motor ambulances and a personnel of more than fifty men and twenty medical officers.

Within eighteen minutes after the order was received the first ambulance was leaving Camp Zackary Taylor for the scene. The order came after taps, and the officers and men were aroused by messengers who communicated the orders silently through the camp without causing the slightest confusion.

The ambulance companies were from Omaha and Flint, Mich.

The conduct of the soldiers was praised by all who witnessed it, as they rendered valuable aid to the injured. Especially noticeable was the way the injured were handed from the cars through the windows on stretchers without the slightest confusion.

Eighty-Ninth Division, Camp Funston, Fort Riley, Kan.

Dec. 18, 1917.

Lieut.-Col. J. L. Shepard, the division surgeon of the Eighty-Ninth Division, is in the East on a short leave of absence, during which time he intends to visit some of the other cantonments and come back through Washington, D. C. Lieut.-Col. Frank Weed is acting division surgeon during his absence.

The following promotions have occurred in this division since its organization until date: F. W. Weed, major, M. C., to lieutenant-colonel, M. C.; Capts. C. S. McGinnis, G. W. Newell, B. Ffoulkes, J. D. Bartlett and R. H. Meade to be majors; Lieuts. C. K. Barclay, W. L. Hall, O. L. Garlinghouse, L. E. Toney, C. C. Johnson, L. G. Harney, W. T. Cullion, P. K. Sauer, B. C. Dorset, F. M. Manson, J. G. Janney, W. B. Heagerty, C. E. Jenkins, C. Powers, Samuel Adams, G. E. Eggloff, C. M. Fuson, W. C. Kent, A. E. Davenport, D. D. Gill, J. H. Kirkham and W. A. Beckemeyer to be captains.

DISEASE CONDITIONS AMONG TROOPS IN THE UNITED STATES

Extracts from Telegraphic Reports Received in the Office of the Surgeon-General for the Week Ending Dec. 14, 1917

1. Total strength of troops in United States as reported......1,001,318
    Annual admission rate per 1,000 (disease only)......... 1,729.7
    Non-effective rate (all divisions) 43
2. National Guard, strength (divisions in United States)...... 367,153
    Annual admission rate per 1,000 all divisions (disease only) 1,757.7
    Non-effective rate all divisions (all causes) 48.6

Divisions showing admission rate for disease higher than average: Camps Bowie, Kearny, Doniphan, Cody, Wheeler and Shelby.

Divisions showing non-effective rate all causes higher than average: Camps Bowie, Kearny, Wheeler, Beauregard, Shelby, Cody and *Doniphan.*

3. National Army, strength (divisions in United States)..... 440,833
    Annual admission rate per 1,000 all divisions (disease only) 1,887.5
    Non-effective rate all divisions (all causes) 40.4

Divisions showing admission rate for diseases higher than average: Camps Travis, Pike, Zachary Taylor, Funston, Dodge and Dix.

Divisions showing non-effective rate all causes higher than average: Camps Funston, Travis, Pike, Dodge, Zachary Taylor, Jackson, Lee and Lewis.

4. Venereal Disease: *69.7*
    Annual admission rate Regulars in United States *44.6*
    Annual admission rate National Guard (divisions in U. S.).. *74.3*
    Annual admission rate National Army (divisions in U. S.)..

National Guard divisions having rate above average: Camps Logan, Wheeler, Sevier, Bowie, Doniphan, Wadsworth, Hancock and *Shelby.*

National Army divisions having rate above average: Camps *Dix,* Upton, Jackson, Lee, Travis and Dodge.

.... 611

5. Number of cases of pneumonia *114*
    Highest number in any one division (36th) 86

Number of cases of meningitis 30

Highest number in any one division (81st) ....

6. NEW CASES OF SPECIAL DISEASES REPORTED DURING THE WEEK ENDING DEC. 14, 1917

Division	Pneumonia	Dysentery	Malaria	Venereal	Paratyphoid	Typhoid	Measles	Meningitis	Scarlet fever	Deaths	Strength of Command
27th, Wadsworth...	2	...	...	36	..	..	12	..	..	2	31,216

ORDERS TO OFFICERS OF THE MEDICAL CORPS

To Washington, D. C., General Engineering Depot, for duty, and on completion to return to his proper station, Lieut. EDGAR A. BOCOCK.

To Camp Grant, Rockford, Ill., and report in person to the commanding general, for duty, Major GARFIELD L. McKINNEY.

To Washington, D. C., and report to the Surgeon-General of the Army for instruction, Col. ALLEN M. SMITH.

To Camp Sherman, Chillicothe, Ohio, to deliver a course of lectures on camp sanitation, and on completion to return *to his proper station*, Capt. J. GILMORE.

To Washington, D. C., and report to the Surgeon-General of the Army for consultation, and on completion to return *to his proper station*, Major THOMAS D. WOODSON.

To Camp Devens, Ayer, Mass., Camp Upton, L. I., N. Y., Camp Dix, Wrightstown, N. J., to inspect the work of tuberculosis boards, and on completion *to his proper station*, Col. GEORGE K. BUSHNELL.

To Camp Sevier, Greenville, S. C., to report in person to the commanding general, Thirtieth Division, for duty, Lieut. HENRY T. SCHIFFLEY.

To Camp Travis, San Antonio, Texas, Camp Doniphan, Fort Sill, Okla., Camp Bowie, Fort Worth, Texas, Camp Arthur, Waco, Texas, Camp Logan, Houston, Texas, Camp Cody, Deming, N. M., to inspect the laboratory service with special reference to its adequacy for the necessary board of health work in the control of epidemic diseases, and on completion *to his proper station*, Major CLARENCE J. COLE.

To New York City, for temporary duty pertaining to the assembling of the branch of the Division of Finances and Supplies for the Medical Department, and on completion *to return to his proper station*, Col. HENRY D. SNYDER.

To Fort Oglethorpe, and report in person to the commandant, Medical Officers' Training Camp, Camp Greenleaf, for the purpose of organizing and commanding Hospital Train No. 3, Major LAMPHEAR W. WEBB, Jr.

To Fort Benjamin Harrison, Ind., and report in person to the commanding officer of that post for the purpose of commanding Hospital Train No. 2, Major ALEXANDER W. WILLIAMS.

To Fort Benjamin Harrison, Ind., and report in person to the commanding officer of that post for the purpose of commanding Hospital Train No. 3, Major HARRY N. KERNS.

To Fort Benjamin Harrison, Ind., and report in person to the commanding officer of that post for the purpose of commanding Hospital Train No. 4, Major LEOPOLD MITCHELL.

To Camp Sherman, Chillicothe, Ohio, for temporary duty, and on completion *to his proper station*, Major EARL H. BURNS.

To Washington, D. C., and report in person to the Surgeon General of the Army for consultation, and on completion to return *to his proper station*, Lieut.-Col. THOMAS L. RHOADS.

To Camp Doniphan, Fort Sill, Okla., to inspect, and on completion to his proper station, Col. DEANE C. HOWARD.

To Newport News, Va., and report in person to the commanding general, Provisional Division, for duty as divsion surgeon, Lieut.-Col. LARUS D. CARTER.

To Camp MacArthur, Waco, Texas, and report in person to the commanding general, Thirty-Second Division, for duty in connection with the organization and training of the Medical Department, and on completion *to Camp Logan*, Major SAMUEL S. CREIGHTON.

To Hoboken, N. J., and report in person to the commanding general, for duty, Major CHARLES T. KING.

To Richmond, Va., to deliver sixteen lectures on Military Surgery and Medicine, at the Medical College of Virginia, and on completion *to his proper station*, Col. LOUIS J. LA GARDE.

McPHAIL, New York; for temporary duty and on completion *to San Antonio, Texas*, from Forth Ethan Allen, Capt. JOHN D. GULICK, Schenectady; for intensive training in his specialty, Lieut. THOMAS H. RAINES, East View.

To report to Washington, D. C., for temporary duty, and on completion to his proper station, from Army Medical School, Lieut. WALTER G. FOX, Fort Plain; from Fort Myer, Lieut. ABRAHAM L. LOWENTHAL, New York.

To Rockefeller Institute, for instruction, and on completion *to Fort McHenry, Md.*, for temporary duty, from Allentown, Pa., Capt. EDWARD DOWDLE, Oswego; from New York City, Capt. EDWIN G. RAMSDELL, White Plains; Camp Upton, for temporary duty in base hospital, from Fort Oglethorpe, Lieut. HENRY R. KUTIL, New York; for instruction in laboratory work, and on completion to Army Medical School, for duty, Lieut. WALTER S. BENNETT, Glen Falls.

To Washington, D. C., for instruction, Lieut. JAMES B. MURPHY, New York.

To his home and honorably discharged, from Fort Oglethorpe, Lieut. FRANK P. IVES, New York.

North Carolina

To Fort Oglethorpe, for instruction, from duty as a private at Camp Jackson, Lieut. HOLMAN BERNARD, Pinnacle.

To Philadelphia and Pittsburgh, Pa.; Cleveland, Ohio; Detroit and Battle Creek, Mich.; Chicago and Rockford, Ill.; Minneapolis, Minn.; Des Moines, Iowa; Omaha, Neb.; Fort Riley, Kan.; Kansas City and St. Louis, Mo.; Indianapolis, Ind.; Louisville, Ky.; Cincinnati and Chillicothe, Ohio, to examine applicants for the A. S., S. C., and on completion to his proper station, from Washington, D. C., Major R. LEWIS, Raleigh.

To his home and honorably discharged, from Camp Wadsworth, Lieut. MARVIN L. SMOOT, *Fayettesville.*

Ohio

To Camp Cody, Deming, N. M., base hospital, Lieuts. WILLIAM F. MILLHON, Columbus; VIRGIL J. FRUTH, Fostoria.

To Camp Doniphan, Fort Sill, Okla., to examine the command for mental and nervous diseases, from Camp Mills, Lieut. JOHN C. GEORGE, Dayton.

To Camp Kearney, Linda Vista, Calif., for duty, *from Camp Bowie*, Lieut. VICTOR R. SMALL, Columbus.

To Camp Meade, Md., base hospital, from Philadelphia, Lieut. ALLEN N. WISELEY, Ada.

To Fort Oglethorpe, for instruction, Lieut. HARRY E. WOODBURY, Akron.

To New York City, Post-Graduate Medical School, for instruction in urology and dermatology, Lieut. LAWRENCE D. MILLER, Toledo.

To Philadelphia, Pa., for training in his specialty, *from* Camp Greene, Lieut. HOWARD H. DAVIS, Cleveland.

To Rockefeller Institute, N. Y., for instruction, and on completion *to Camp Upton*, L. I., N. Y., base hospital, *from* Fort Oglethorpe, Lieut. CARROLL H. SKEEN, Seneccaville.

To his home and honorably discharged, from Camp Taylor, Capt. ELIJAH W. TIDD, Stockdale.

Oklahoma

To Camp Custer, Battle Creek, Mich., for duty, from Fort Riley, Lieuts. JOHN V. ATHEY, Bartlesville; FRANK A. FANNIN, Stigler.

To Fort Oglethorpe, for instruction, Capt. JOHN C. MAHR, Oklahoma City; from Philadelphia, Lieut. DAVY L. GARRETT, Altus.

To Fort Riley, for instruction, Lieuts. JOSEPH H. STOPLER, Muskogee; EARL L. YEAKEL, Norman.

To Lake Charles, La., Signal Corps, Aviation School, Gerstner Field, from Montgomery, Ala., Lieut. JAMES R. BOST, Cashion.

To his home and honorably discharged, on account of being physically disqualified for active service, from Fort Oglethorpe, Lieut. LOUIS C. KUYRKENDALL, McAlester.

Pennsylvania

To Camp Bowie, Fort Worth, Texas, base hospital, Lieut. FRED D. REYNOLDS, Pittsburgh.

To Camp Cody, Deming, N. M., base hospital, from Fort Oglethorpe, Lieut. ANDREW J. W. HANDWORK, Altoona.

To Camp Devens, Ayer, Mass., base hospital, from Camp Devens, Capt. DANIEL M. HOYT, Philadelphia; from Boston, Lieuts. HENRY C. DOOLING, Norwood Station; ALBERT W. GREENWELL, Philadelphia.

To Camp Doniphan, Fort Sill, Okla., base hospital, from Chickamauga Park, Lieut. JOSEPH D. ARONSON, Philadelphia.

To Camp Grant, Rockford, Ill., base hospital, from Camp Grant, Lieut. ALLEN H. MOORE, Philadelphia.

To Camp Hancock, Augusta, Ga., motor mechanic regiments, from Montgomery, Ala., Lieut. ALBON E. FICHTNER, Conemaugh.

To Camp Logan, Houston, Texas, for duty, from Fort Clarke, Texas, Capt. CAREY J. VAUX, Pittsburgh.

To Camp Meade, Md., for duty, Capt. WILLIAM F. McLAUGHLIN, Philadelphia; base hospital, from Philadelphia, Lieut. LOUIS H. MAYER, Johnstown.

To Camp Pike, Little Rock, Ark., base hospital, from Army Medical School, Lieut. SOLOMON F. HOGE, Philadelphia.

To Camp Sherman, Chillcothe, Ohio, for duty, from Fort Oglethorpe, Lieut. JESSE B. HOWE, Erie.

To Camp Wheeler, Macon, Ga., base hospital, from Camp Wheeler, Lieut. JOHN H. STEARNS, Delaware Water Gap.

To Fort McHenry, Md., for temporary duty, from Allentown, Pa., Lieut. ALEXANDER D. FERGUSON, Eddystone.

To Fort Oglethorpe, for instruction, Lieuts. SAMUEL A. KAMERER, Ellsworth; FRANCIS M. S. SCHAM, Johnstown; JOHN D. DONNELEY, Philadelphia; from Boston, Lieut. SUMNER C. SIMPSON, Pittsburgh; from New York City, Lieut. PHILIP J. LUKENS, Jr., Philadelphia; from Philadelphia, Lieuts. GEORGE H. FAGGERT, FRANK G. MURPHY, Philadelphia; Hospital Train No. 27, from Fort Oglethorpe, Lieut. HOWARD C. HEILMAN, Pittsburgh.

To Newport News, Va., to reexamine the troops for tuberculosis, from Camp Meade, Lieut. WILLIAM H. HERR, Lancaster.

To New York City, for intensive training, Lieut. DAVID B. HAWKINS, Curwensville; Post-Graduate Medical School, for instruction in urology and dermatology, Lieut. DAVID P. McCUNE, Jr., McKeesport.

To Philadelphia, for duty, Major CHARLES F. HASSAN, Philadelphia; for instruction in traumatic surgery and fractures, Major EDWARD MARTIN, Philadelphia; for intensive training, Capt. WILLIAM W. RICHARDSON, Mercer.

To Pittsburgh, Hospital Unit "L," Allegheny General Hospital, from Camp Hancock, Major WALTER A. DEARTH, Pittsburgh.

To Takoma Park, D. C., for duty, from New York City, Lieut. CHARLES E. YOHO, Pittsburgh.

To Washington, D. C., for a conference and on completion to his proper station, from Evans Institute, Philadelphia, Capt. CARLTON N. RUSSELL, Philadelphia, Camp American University, for duty, from Fort Oglethorpe, Lieut. WILLIAM J. HARRISON, Philadelphia.

To his home and honorably discharged, from Camp Bowie, Capt. JOSIAH T. BUNTING, Philadelphia; from Camp Green, Lieut. WILLIAM F. McANALLY, Philadelphia; from Camp Jackson, Lieut. CLARENCE W. LURTING, Pittsburgh.

Rhode Island

To Camp Kearney, Linda Vista, Calif., base hospital, from Camp Kearny, Lieut. JOHN P. JONES, Wakefield.

South Carolina

To Camp Sherman, Chillicothe, Ohio, for duty, from Fort Oglethorpe, Lieut. JOHN M. BEARDEN, Lawrence.

To Fort McHenry, Md., for temporary duty, from Allentown, Pa., Lieut. JOHN R. BOLINE, Columbia.

To Fort Oglethorpe, for instruction, Lieut. LEWIS M. GRIFFITH, Columbia.

Honorably discharged on account of being physically disqualified for active service, Lieut. ARTHUR D. MORGAN, North.

South Dakota

To his home and honorably discharged on account of being physically disqualified for active service, Lieut. ALBERT S. RIDER, Flandreau.

Tennessee

To Austin, Texas, for duty, from Everman, Texas, Lieut. FLEMING J. O'CONNER, Jackson.

To Camp Bowie, Fort Worth, Texas, to examine the command for mental and nervous diseases, from Camp Lee, Lieut. HOWARD M. FRANCISCO, Nashville.

To Camp Sherman, Chillicothe, Ohio, for duty, from Fort Oglethorpe, Lieut. JOHN S. MILLER, Callierville.

To Fort Barrancas, Fla., for duty, from Camp Shelby, Lieut. DANIEL B. CLIFFE, Franklin.

To Fort Oglethorpe, for instruction, Lieuts. ELLIS LeR. WILKINS, Dyersburg; ROBERT E. SULLIVAN, Nashville; Hospital Train No. 22, from Fort Oglethorpe, Lieut. EMMETT E. BROWN, Nashville.

Texas

To Army Medical School, for duty, from Fort Clark, Lieut. LEVY S. JOHNSON, Richmond.

To Camp Lewis, American Lake, Wash., for duty, from Camp McArthur, Lieut. JAMES J. JOHNSON, Sulphur Springs.

To Camp McClellan, Anniston, Ala., for duty, from Fort Oglethorpe, Capt. JESSE L. WOMACK, Lolita.

To Fort Oglethorpe, Evacuation Hospital No. 6, from Fort Oglethorpe, Lieut. BENJAMIN F. LARGENT, McKinney; for instruction, Lieuts. NEWELL W. ATKINSON, Alice; EDWARD W. TISDALE, Clyde; JAMES A. SHACKELFORD, Thurber; from Boston, Lieut. ROBERT L. HOWELL, Snyder.

To Indianapolis, for duty, and on completion to return to his proper station, Major JOHN B. McLEAN, Fort Worth.

To Rockefeller Institute, for instruction and on completion to Camp Upton, L. I., N. Y., base hospital, from Fort Oglethorpe, Lieut. THOMAS R. SEALY, Santa Anna.

To South San Antonio, Texas, Kelly Field, in connection with the Physical Examining Unit, Capt. TARLETON F. MOORE, Galveston.

To Washington, D. C., Camp American University, from Fort Oglethorpe, Lieut. DAVID C. WILLIAMS, Post.

Utah

To Camp Lewis, American Lake, Wash., for duty, from Fort Riley, Capt. CHAUNCEY M. BENEDICT, Salt Lake City.

Vermont

To Fort Oglethorpe, for instruction, Lieut. GEORGE C. RUBLEE, Hardwick

To Philadelphia, for temporary duty and on completion to San Antonio, Texas, from Fort Ethan Allen, Lieut. ARTHUR L. LARNER, Burlington.

Virginia

To Camp Devens, Ayer, Mass., for duty, from Fort Sill, Major CHARLES A BROWN, Dillwyn; base hospital, from Boston, Lieut. PERCY E. DUGGINS, Norfolk.

To Camp Jackson, Columbia, S. C., base hospital, from Fort Oglethorpe, Lieut. QUINTUS H. BARNEY, Richmond.

To Camp Lewis, American Lake, Wash., for duty, from Fort Riley, Lieut. WILLIAM E. BROWN, Catawaba Sanatorium.

To Camp Pike, Little Rock, Ark., base hospital, from Philadelphia, Capt. HOWARD FLETCHER, Fairfax.

To Camp Wadsworth, Spartanburg, S. C., base hospital, from Fort Oglethorpe, Lieut. MAURICE A. SELINGER, City Point.

To Fort Oglethorpe, for instruction, Lieuts. FRANK W. LEWIS, Merattica; CHARLES E. LLEWELLYN, Richmond.

To Newport News, Va., for duty, Capt. SAMUEL A. RIDDICK, Smithfield.

To Rockefeller Institute, for instruction, and on completion to Takoma Park, D. C., for temporary duty, from Fort Oglethorpe, WILSON H. DRIVER, Norfolk.

Washington

To Camp Lewis, American Lake, Wash., for duty, from Camp Bowie, Capt. ISAAC W. POWELL, Bellingham.

Honorably discharged on account of holding commission in the National Guard, Capt. JOHN B. KINNE, Aberdeen.

West Virginia

To Camp McClellan, Anniston, Ala., for duty, from Fort Oglethorpe, Lieut. HARVEY C. POWELL, Morgantown.

To Fort Oglethorpe, for instruction, from Fort Ethan Allen, Lieut. HARRY D. LAW, Conings.

To New York City, for intensive training in his specialty, Lieut. ROSS DODSON, Spencer.

Wisconsin

To Arcadia, Fla., Signal Corps, Aviation School, Carlstrom Field, from Montgomery, Ala., Lieut. RAYMOND A. HEBRON, Cataract.

To Camp Cody, Deming, N. M., base hospital, from Fort Riley, Lieuts. EZRA J. MITCHELL, Brodhead; CLARK O. DECKER, Crandon; HARRY E. GILLETTE, Packwaukee; HARRY C. McCARTHY, Richland Center.

To Camp Devens, Ayer, Mass., to examine the command in mental and nervous diseases, from New York City, Lieut. CHARLES C. ROWLEY, Winnebago.

To Camp Hancock, Augusta, Ga., motor mechanic regiments, from Montgomery, Ala., Lieuts. ALBERT H. KULIG, Dodge; CHARLES M. PEARSON, Ogema; EDWARD P. EVANS, South Milwaukee.

To Camp McClellan, Anniston, Ala., for duty, from Fort Oglethorpe, Lieut. WILLIAM E. ALLEN, Sun Prairie.

To Dayton, Ohio, Wilbur Wright Station, Aviation General Supply Depot, McCook Field, from Montgomery, Ala., Lieut. ATHOL H. WEDGE, Waupun.

To Fort Leavenworth, Kan., for duty, from Fort Riley, Lieut. FRANKLIN M. HAWLEY, Bayfield.

To Fort Riley, base hospital, Lieut. ABRAHAM B. SCHWARTZ, Milwaukee.

To Fort Slocum, N. Y., for duty, from Neurological Institute, N. Y., Lieut. SMILEY BLANTON, Madison.

To Great Lakes, Ill., to observe construction, organization, equipment and administration of the hospital at the Naval Training Station, and on completion to return to his proper station, Major NELSON M. BLACK, Milwaukee.

To Philadelphia, for instruction in orthopedic surgery, Lieut. BERNARD O. BENDIXEN, Kewaskum.

Honorably discharged on account of being physically disqualified, apt. GUSTAF R. EGELAND, Sturgeon Bay.

CORRECTION

Under "Orders to Officers of the Medical Reserve Corps" in the issue of November 3:

Lieut. JOHN D. MILLER, of Little Falls, N. Y., instead of Cincinnati, O., was ordered *to Camp Grant*, Rockford, Ill., for duty with the 35th Engineers.

Issue of December 15: Lieut. HERBERT L. WILLIAMS, Auburn, Me., instead of Bartonville, Ill., was ordered *to Camp Gordon*, Atlanta, from Fort Oglethorpe.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

FLORIDA

Addition to Hospital.—The addition to the Lee County Hospital, Fort Myers, is practically completed, giving the institution six new rooms, four of which have already been furnished.

New Officers.—Escambia County Medical Society, at Pensacola, December 11: president, Dr. L. de Blocker, Pensacola; vice president, Dr. William D. Nobles; secretary, Dr. Fritz A. Brink, and treasurer, Dr. Walter C. Payne, all of Pensacola.——Hillsborough County Medical Society, at Tampa, December 4: president, Dr. Reuel A. Fly; vice president, Dr. Leland F. Carlton; secretary, Dr. Gilbert H. Hodgson, and treasurer, Dr. Jesse J. Saxton, all of Tampa.——Du Val County Medical Association, at Jacksonville, December 4: president, Dr. Frederick J. Waas; vice president, Dr. William E. Ross, and secretary-treasurer, Dr. Elmo D. French, all of Jacksonville.

GEORGIA

New Sanatorium Building.—Advertisement has been made by the board of trustees of the Georgia State Sanatorium, Milledgeville, for proposals for the construction of a sanatorium building.

New General Hospital.—The Military Hospital at Fort McPherson, Atlanta, has been changed from a base hospital to a general hospital. The new hospital will remain in command of Col. Thomas S. Bratton.

New Officers.—Randolph County Medical Society at Cuthbert, December 11: president, Dr. John L. Shephard, Carnegie; vice president, Dr. Thomas F. Harper, Coleman, and secretary-treasurer, Dr. George Y. Moore, Cuthbert.

Public Health Service Furnishes Health Officers.—P. A. Surg. Charles L. Williams, U. S. P. H. S., is to become health officer of Macon. Dr. Charles Wardell Stiles, U. S. P. H. S., has arrived in Augusta to take charge of the health situation in the zone contiguous to Camp Hancock.

Personal.—Dr. Craig Barrow, Savannah, has been appointed chief surgeon of the Central Georgia Railroad and Ocean Steamship Company, succeeding Dr. William W. Owens, deceased. Dr. Barrow has appointed Dr. Lawrence Lee as assistant surgeon.——Dr. Roger C. Swint has been appointed clinical director of the State Sanatorium, Milledgeville, succeeding Dr. Edward M. Green, resigned to accept the superintendency of the Pennsylvania State Sanatorium.

ILLINOIS

Chicago

Fire in Fraternity House.—Medical students were routed from bed, December 17, when the Phi Rho Sigma fraternity house of Northwestern University caught fire. The damage to the building was estimated at $500.

Dispensary Moves.—The Army Dispensary formerly in the Federal Building was moved, December 22, to its new quarters at 820 Michigan Boulevard Building. Major Samuel C. Stanton, M. R. C., is in command and has as his assistants, Capt. Albert H. Rober, M. R. C., and Lieuts. Claude H. Ogden, M. R. C., Roy R. Haley, M. R. C., and Charles B. Gibson, M. R. C.

Society of Internal Medicine.—At the twentieth regular meeting of the Chicago Society of Internal Medicine, December 17, the program included papers by Dr. Lewis J. Pollock and William Cluney on "Vital Stains and Central Nervous System"; by Dr. Arthur F. Beifeld on "An Etiologic Phase of Pernicious Anemia," and by Drs. Rollin T. Woodyatt and William D. Sansum, on "Treatment of Mercuric Chlorid Poisoning: An Experimental Study."

INDIANA

Physicians Win Suit.—In the damage suit for $25,000 brought against Drs. James H. Fargher and Orlando L. Sutherland, La Porte, in which the defendants were charged with failing properly to set a fracture of the ribs, a verdict was rendered in the St. Joseph circuit court, December 14, in favor of the physicians.

Personal.—Dr. Sterling P. Hoffmann, Bluffton, is ill with smallpox.——Dr. J. Rilus Eastman, Indianapolis, spoke before the Madison County Medical Society, November 27, on "War Surgery."——Dr. Rose Alexander Bowers, Michigan City, has been appointed a member of the staff of the Mayo Clinic, Rochester, Minn.——Dr. Edward J. McOscar, Fort Wayne, was awarded the first prize for the best paper read at the annual meeting of the Pennsylvania Railway Surgeons' Association.

Smallpox.—The state board of health will, it is expected, soon take drastic action to check the spread of smallpox in the state. The board of health of Indianapolis has already initiated such action, and requires that all children be vaccinated.——During November, ninety cases of smallpox were reported in Indianapolis, and during the first ten days in December, sixty-five additional cases were reported.——The health authorities of Fort Wayne believe that they have the smallpox epidemic under control.——A number of cases of smallpox are said to have developed at Grabill.

IOWA

Field Hospital Unit Mustered.—The field hospital unit was mustered in at Iowa City, December 8, under command of Major Francis L. Love, Iowa City.

Personal.—Dr. Frank W. Lee, Riceville, fell to the bottom of his silo chute, December 10, sustaining severe injuries.——Capt. Daniel J. McCarthy, Davenport, is in charge of the second Red Cross Hospital, opened at Jassy, Roumania, December 4.

New Officers.—Dubuque County Medical Society, at its annual meeting, December 11, in Dubuque, elected the following officers: president, Dr. Joseph H. Schrup; vice presidents, Drs. Frank W. Meyers, Dubuque, and Hierstein, Dyersville; secretary, Dr. Clarence E. Lynn, and treasurer, Dr. Henry M. Pahlas, Dubuque.

Hospital Items.—At a meeting of the authorities of Grinnell College with the Women's Club of the city, the plans for a detention hospital for contagious diseases were endorsed, and a committee was appointed to secure the funds for the erection.——Miss Lottie Heywood has been placed temporarily in charge of the Eleanor Moore Hospital, Boone.——Two wards and a number of private rooms have been added to the Anamosa Hospital, which now has accommodation for twenty patients.

MARYLAND

Personal.—Capt. Clement A. Penrose, Baltimore, has returned from a four months' visit to London, Paris, and the trenches in France and Flanders, commissioned to make an investigation of sanitary conditions.——Dr. Archibald C. Harrison, who holds a commission as major in the University of Maryland Hospital Unit, has returned to his home in Baltimore, after spending several week in Virginia, recuperating from a serious operation.

Memorial to Dr. Chambers.—In the main operating room at the Mercy Hospital, an impressive bronze tablet of the late Dr. John W. Chambers has been erected as a memorial to him by the Alumni Association of the College of Physicians and Surgeons. The tablet is a medallion portrait of Dr. Chambers, and is the work of Maxwell Miller, the local sculptor. There were no formal exercises at the unveiling of the memorial, which was private, and in the presence of the members of Dr. Chambers' family, with Sisters of Mercy and the resident staff of the hospital.

MASSACHUSETTS

Whooping Cough Hospital.—What is said to be the first hospital in the United States devoted to pertussis was opened, December 7, in one of the buildings of the west department of the City Hospital.

Federal Hospital on Long Island.—It is announced that Long Island, Boston Harbor, will be taken by the federal government for hospital purposes. The mayor of Boston will use the $1,300,000 realized by the sale to build 500 cottages for the sick and poor now on the island.

Work of Women on Battlefields.—Dr. Rosalie Slaughter Morton, New York, chairman of the war service committee of the Woman's National Medical Association, was a guest of honor at a dinner of the Women's National City Club, Boston, December 5. Dr. Morton described the work of women in the battlefields and hospitals of France, Belgium and Serbia.

Addition to Hospital.—The Municipal Council of Haverhill has appropriated $70,000 for the erection and equipment of an addition to the Glen Gale Hospital. The plans provide for a two-story brick structure to be erected in the rear of the present hospital, increasing its capacity from fifty to 100 patients. It is also proposed to establish a general medical dispensary and outpatient department at the hospital.

Personal.—Dr. Wallace C. Keith, Brockton, was installed as grand master of the Grand Council of Masons at the annual meeting in Boston, December 10.——Dr. Halbert C. Hubbard, Worcester, has been appointed assistant physician to the State Sanatorium, Rutland.——Drs. M. Victor Safford, Honore Van De Velde and Benjamin A. Graves, Boston, were deputized by the mayor to go to Halifax, N. S., and give such aid as they could to the people of the afflicted city.

MONTANA

Smallpox.—In Butte and Silver Bow counties there are said to be 150 cases of smallpox, many of which are of the most malignant type, and compulsory vaccination is suggested by the authorities.

Personal.—Dr. Arthur Morrow, Kalispell, has been named as physician of Flathead County and health officer of Kalispell.—— Dr. Max W. Barbour has been appointed health officer of Helena, succeeding Dr. Ellis A. Johnston, resigned.

NEW JERSEY

Personal.—Dr. John J. Broderick has been appointed surgeon of the police department of Jersey City.——Lieut. James H. Haines, M. R. C., Haddon Heights, is reported to be seriously ill with measles at Camp Pike.

Loyalty Meeting.—A patriotic meeting of the physicians of Trenton and their families was held, December 13, at which Dr. William W. Keen, Philadelphia, and Major Charles A. E. Codman, M. R. C., U. S. Army, Philadelphia, delivered addresses, and Major Henry D. Jump, Philadelphia, presented moving pictures of war conditions abroad and of cantonments in this country.

Clinic for Syphilis.—In compliance with a resolution adopted recently by the Morris County Medical Society that "If possible, at least three hospitals in the county establish a clinic for the treatment of syphilis or specific blood disorders," the board of managers of the New Jersey State Hospital at Morris Plains at its recent annual meeting authorized the establishment of such a clinic at this hospital. Through the liberality of private concerns, the necessary drugs are to be provided without expense to the hospital or state.

NEW YORK

Offers Estate for Convalescent Home.—Froh Heim Farms, the 5,000-acre country estate of the late Grant B. Schley, New York, has been offered by his heirs to the government for a home for convalescent soldiers.

Vassar to Train Nurses.—A committee of the trustees of Vassar College has been appointed to work out plans for a school for the intensive training of registered nurses. In cooperation with the committee on nursing of the Council on National Defense it is also planned to hold a summer conference of Red Cross home service workers, and to establish a normal institute under the auspices of the American Red Cross.

Medical Military Aid.—The American Medical Military Aid Association was incorporated in New York, December 15. The purpose of the association is "To give voluntary medical aid and voluntary assistance to the dependent families of men enlisted in the United States Army and Navy." The directors are Drs. John Ernest Gignoux, Wolff Freudenthal, Mary L. E. Daly McLean, Freeman F. Wood, Isadore L. Hill and Robert Emery Brennan, Mrs. Florence Eno Graves and Mr. Willis G. Nash, all of New York.

New York City

The Flint Estate.—The estate of the late Dr. Austin Flint, who died, Sept. 21, 1915, has been appraised at $144,518 gross. It is to be divided between his two sons and a grandson.

Tubercuosis Hospial Admission Bureau Moves.—The Hospital Admission Bureau, which is maintained jointly by the department of health and the Department of Public Charities, has removed from First Avenue near Twenty-Fifth Street to 145 Worth Street, where it will be more easily accessible and where larger quarters have been secured.

Pneumonia Continues to Increase.—While New York is not suffering from an epidemic of pneumonia, the disease has been unusually prevalent not only in the city but throughout the state, and both the city and state health departments have been keeping before the public the fact that pneumonia is an infectious and communicable disease and one that is to a large extent avoidable if proper precautions are taken. For the week ended December 14 there were, out of 1,443 fatalities, 263 due to pneumonia; for the preceding week, out of 1,417 deaths, 220 were caused by pneumonia. The average number of deaths from pneumonia for this time of year in this city is about 200. While there is usually an increase in the number of deaths from respiratory diseases as the winter progresses, this year the increase began earlier and has continued at a much higher rate than usual.

Personal.—Dr. Thomas Darlington, formerly health commissioner in New York, has been engaged permanently as sanitary commissioner of the American International Ship Building Co.——Dr. Walter J. O'Connell of the Buschwich Hospital was seriously injured in a collision between an ambulance of the hospital and a street car, December 10.——As a result of a competitive examination for the position of chief medical examiner of New York, Dr. Otto H. Schultze, pathologist to the district attorney, and Drs. Charles Norris and Douglas Symmers of the pathologic laboratories of the Bellevue Hospital have qualified for the position. The new examiner takes the place formerly held by the coroner.——Drs. Burr B. Mosher, John Osborn Polak, Sylvester J. McNamara, Jaques C. Rushmore, Henry M. Mills and Henry M. Moses, all of Brooklyn, has been appointed councilors of the Long Island College Hospital Alumni Association.

OHIO

Smallpox in Toledo.—Smallpox is reported to be unusually prevalent in Toledo. It is stated that there are approximately 20,000 unvaccinated children in public schools.

Academy Election.—At the annual meeting of the Muskingum County Academy of Medicine, held in Zanesville, December 12, Dr. Leroy F. Long was elected president; Dr. William F. Sealover, vice president, and Dr. Oren I. Dusthimer, secretary-treasurer.

Personal.—Dr. Edward Herbst, Columbus, who is about to retire as a member of the board of education, took the highest rank in the recent civil service examination for city physician.——Dr. Rush R. Richison, Yellow Springs, assumed his new duties as superintendent of the District Tuberculosis Hospital, Springfield, December 21.——Dr. Edward J. Schwartz, for fifteen years health officer of Salem, has resigned to accept the position of director of communicable diseases in the state department of health.

PENNSYLVANIA

Personal.—Dr. W. Edgar Holland, Fayetteville, has been elected physician to the Franklin County Home, succeeding Dr. John K. Gordon, Chambersburg.——Dr. Mary Janet Alexander, Chester, has resigned to take up work as a medical missionary in India.——Dr. Jesse Cope Green, a well known dentist of West Chester celebrated his 100th birthday anniversary, December 13.——Dr. Oliver C. Heffner, Pottstown, received severe burns of the face and hands while pouring an antifreezing solution into his automobile.——Dr.

Edward L. Davis, Berwick, has been appointed coroner for Columbia County, to succeed Dr. William H. Hoffa, deceased.

Philadelphia

Personal.—Lieut. Hugh Cotter Boyle, formerly of the British Ambulance Corps No. 17, with the rank of regimental surgeon, and later transferred to the Second Durham Infantry, was severely wounded in action in France, December 7. Dr. Boyle served for a year as an intern in the Samaritan Hospital, and practiced in this city until last May.——Dr. Samuel G. Dixon was reelected, for the twenty-second consecutive time, president of the Academy of Natural Science at the annual meeting, December 18.

TEXAS

Free Clinic.—The health department of Amarillo has established a free clinic at the Amarillo Hospital, which will be held for two hours each week for the benefit of indigent patients.

Hospital for Tuberculous Negroes.—The health department of Dallas has asked the county commissioners' court to appropriate a sum of money for the construction of a hospital to be used for the treatment of negroes suffering from tuberculosis.

North Texas Physicians Meet.—At the seventy-sixth semiannual meeting of the North Texas Medical Association, held in Dallas, December 11 and 12, the following officers were elected: president, Dr. H. Leslie Moore, Dallas; vice president, Dr. Sidney J. Wilson, Fort Worth; secretary, Dr. David L. Bettison, Dallas, and treasurer, Dr. Martin L. Wilbanks, Greenville. A committee was appointed to petition congressmen and senators to eliminate that portion of Section 2120, of the Emergency War Revenue Act, which provides a professional tax of an additional 8 per cent.

State Health Board Notes.—A meeting of the state board of health was held at Laredo, December 10, to discuss the work of the present year, and outline plans for the coming year, and to consider the Mexican border quarantine service and other matters of public importance.——Dr. David E. Rouse, epidemiologist to the Ohio State Board of Health, and director of Red Cross Unit No. 12, Chillicothe, Ohio, has been appointed field director by the state board of health.——Dr. Albert H. Braden, Beaumont, has been appointed a field director by the state board of health, and will have charge of the work in McLellan County.

WASHINGTON

New Health Officer, Chemist and Bacteriologist for Tacoma.—Dr. Hilbrand J. Hards has been appointed health officer of Tacoma, succeeding Dr. Jonathan E. Henry, resigned, to take effect, January 18.

New County Officers.—At the meeting of the Whatcom County Medical Association, held in Bellingham, December 10, the following officers were elected: president, Dr. Edward W. Stimpson; vice presidents, Drs. Carl C. Hills, Albert M. Dawson and Newton W. Wear; secretary, Dr. Orville E. Beebe, and treasurer, Dr. Frank J. Van Kirk, all of Bellingham.

GENERAL

Rutland Railway Surgeons Elect Officers.—At the annual meeting of the Rutland Railway Surgeons' Association, held in Burlington, Vt., December 13, the following officers were elected: president, Dr. James M. Hackett, Champlain, N. Y.; vice president, Dr. Joel B. Woodhull, North Bennington, Vt., and secretary-treasurer, Dr. Stanton S. Eddy, Middlebury, Vt.

Bequests and Donations.—The following bequests and and donations have recently been announced:

Building fund of the People's Hospital, New York, a donation of $5,000 from Louis Koenberg, and $3,000, the proceeds of a theatrical benefit.

King Edward's Hospital Fund, London, a donation of $175,000 from Viscount Astor.

Provident Hospital, a contribution of $1,000 in cash by negroes of the city.

New Officers for Southwestern Association.—At the fourth annual meeting of the Southwestern Medical and Surgical Association, held in Albuquerque, N. M., December 7 and 8, the following officers were elected: president, Dr. Percy G. Cornish, Albuquerque, N. M.; vice presidents, Drs. W. Warner Watkins, Phoenix, Ariz., and Charles G. Duncan, Socorro, N. M., and secretary-treasurer, Dr. John R. Van Atta, Albuquerque. El Paso was selected as the next place of meeting.

Mary Pemberton Nourse Fund for Public Health Study.—The Mary Pemberton Nourse Fund for Public Health Study has been established by the class of 1914 of Vassar College in memory of Mary Nourse of that class, who dedicated herself to the cause of public health, but whose aim was cut short of realization. This fund is established for the purpose of offering a fellowship to young women who desire to devote themselves to the important work of public health, and is recommended for consideration by Julia C. Lathrop, chief of the Children's Bureau, United States Department of Labor; Dr. William H. Howell of Johns Hopkins University, School of Hygiene and Public Health, and Henry N. MacCracken, president of Vassar College. The sum at the disposal of the class is to be increased until the income from it will provide opportunity for continued and valuable work in this field. An appeal is now being sent out for gifts of money, and especially of Liberty Bonds, to bring the sum up to the required amount. Coupon bonds and contributions may be sent to the chairman, Katherine Taylor, 330 Webster Avenue, Chicago.

PARIS LETTER

Paris, Nov. 29, 1917.

Surgery of Nerve Trunks

At one of the recent sessions of the Société de chirurgie de Paris, Dr. Chevrier, hospital surgeon, presented an interesting communication on the technic of the repair of injured nerve trunks. The operation may consist of a liberation, a total suture or a partial suture of the nerve. Chevrier never approaches the nerve at the level of the lesion, but always either above or below, always working without instruments so as not to contuse the nerve; next, he frees it of its coverings; then he scarifies the surface with the point of a bistoury, and, finally, he ensheaths it in amniotic membrane. For total suture, it is convenient, as a preliminary step, to mobilize the nerve for quite a stretch above and below, which favors the bringing together of the nerve ends after the resection. The resection must be extensive enough to obtain a nerve end of the same appearance as is obtained after cutting a normal nerve. Experience has taught Chevrier that he must resect a little more than the hard, indurated mass in the old cases, and a little less than this in the recent cases. The section should be made with a thin, sharp bistoury, not with scissors, because they crush or bruise the nerve. Chevrier makes the section perpendicular to the nerve axis in both stumps. The circular surfaces thus obtained lend themselves to better placing of the suture, and reduce to a minimum the possibility of displacement of the axis cylinder. The suture should aim to be an exact circumferential approximation of the nerve stumps. Chevrier places separate sutures of catgut, including the neurilemma and the most superficial part of the nerve. He puts in many sutures, separated by forceps arranged in order. It is important that when these sutures are tightened the nerve ends are brought together without crushing or bruising. If the nerve ends are not brought in contact by this procedure, the threads are tightened by twisting the ends, going over them in turn several times. The coaptation of the nerve ends may be facilitated by lessening the tension on the nerve itself: flexing the leg for the nerves of the thigh, flexing the forearm to relieve the tension on the median and the radial nerves; extending and adducting to ease up on the ulnar.

PARTIAL SUTURE

In the case of partial suture, the difficulties are found in the resection. It is important that the principle of removing the whole of the indurated fibrous mass must be respected, and that is a difficult matter. By being too conservative, this fundamental principle is not observed. Hence partial resections give results inferior to those obtained with total suture. If the case is one which apparently does not lend itself to a complete resection of the indurated fibrous mass, a resection is nevertheless preferable to a partial suture, even though some normal fibers have to be cut, because a perfect total suture will certainly be followed by regeneration. With this reservation, resection preliminary to partial suture can be effected in several different ways; it may be cuniform, trapezoid or rectangular. The last mentioned is the one preferred by Chevrier, because it gives better approximation. The suturing is done at separate points, but the immediate result does not look so well as that obtained from total suture, because of the hump formed by the sound part of the nerve that has been left intact. The suture completed, the union is wrapped in amniotic membrane.

AFTER-CARE AND OUTCOME

Chevrier insists on the importance of complete asepsis in the performance and after-care of this operation. When the extremity has been placed in an abnormal position for the purpose of lessening the tension on the nerve, it is kept in such a position on an average for three weeks; then it is gradually returned to its normal position. He has never seen a case where the abnormal position became permanent. This technic has yielded the best results; for example: Chevrier's personal experiences in the cases involving the external popliteal nerve are as follows: two liberations, reviewed and followed, have both been cures. Of six total sutures, two were not followed beyond the fourth month, but there is every reason to hope that the result in these cases is a good one. The remaining four cases have been followed and reexamined. They were all cured with complete return of motion.

WALTHER'S TECHNIC

Dr. Walther, assistant professor at the Faculté de médecine de Paris, and surgeon of the hospitals, speaking of the liberation of nerves, said that it is not always possible to accomplish this without the use of instruments as, for instance, when the nerve is included in a mass of thick, fibrous tissue. For some time it has been his practice to effect such liberation with a small, blunt tenotome, used on the flat. As concerns nerve suture, to avoid the turning back of the nerve fibers, which may result from too accurate apposition of the nerve ends, he has followed a method of impacting the nerve ends, hollowing out one end and rounding off the other, so that all the parts of the nerve, especially the central, will be in contact without pressure. He directed attention to a very important question, namely, that of the indication for operation as determined during the operating. Chevrier is guided by the results of electric exploration of nerve function, which is all very well, but when the result is negative, one cannot draw any conclusions as to the nature of the interruption of nerve function; one does not know whether the axis cylinders are embedded in the cicatrix and thus are blocked, or whether they have forced their way through the cicatrix and have penetrated the lower end of the nerve. All that a negative result shows is that the nerve fibers have been completely destroyed. It only remains to determine the position of the lesion and the consistency of the fibrous mass, to decide on the operation to be performed. If there is present a large fibrous mass, well isolated, encapsulated, as it were, a neuroma or a glioma, Walther believes that it is well to remove it, endeavoring, by means of a longitudinal incision, to shell it out, observing all precautions not to bruise or crush the tissues of the nerve embedded in it. When it is a case of diffuse induration, enucleation is out of the question; the only choice is between total resection with suture of the two ends or conservation of the trunk with its cicatricial tissue. In any event, it is convenient to perform the last mentioned operation only if medical treatment, carried on for many months, has failed to show any improvement in the condition of the nerve.

Dr. Quénu, clinical professor of surgery at the Faculté de médecine de Paris, also stated that it is impossible, in certain cases, to know just what part the cicatricial tissue plays; it is wrong to say that this tissue must be removed in every case, especially when such removal would necessitate making extensive resection.

CHAPUT'S TECHNIC

Dr. Chaput, surgeon of the hospitals of Paris, believes that nerve suture can be done by a technic more simple than that of Chevrier. He recommends suture of the neurilemma as being logical in principle, although difficult of execution, because of the possible hernia of the nerve fibers. The conditions for success in nerve suture depend always on the technic employed, local conditions and the general state of the patient. From the point of view of technic, Chaput prefers simple catgut, which is less irritating than silk or chromic catgut. Few sutures should be taken, and they should be placed as near the edge of the nerve as possible so as to avoid the turning back or overlapping of the nerve ends. These sutures should not be drawn tight: the two nerve ends should merely be in contact, and not too closely in contact either, for the postoperative congestion increases the compression of the nerve tissue, and even though the suture is not tight, it brings the ends in contact. Finally, the sutured nerve should not rest on a hard bed, such as bone, but on an interposed muscular bed. The general state of the patient is also of very great importance. First, the age. The operation is not a success in the old; it is much more successful in the young. Alcoholics, syphilitics, those suffering from intoxications, tuberculosis, kidney, liver or heart disease or arteriosclerosis, are in very poor condition for nerve suture, and it is among these that failures are observed most often.

LONDON LETTER

London, Nov. 27, 1917.

The War

VITAL STATISTICS

In his presidential address to the Royal Statistical Society, Sir Bernard Mallet, the registrar-general of births, marriages and deaths, referred to the overwhelming importance of the whole question of racial advance or decline, on which the fate of nations so largely depends, and to the damage that the present struggle must inflict on this and other nations. Dealing with the effect of war on marriages, he said that the number of marriages increased steadily from 260,544 in 1909 to 286,583 in 1913, and that this increase was continued in the first two quarters of 1914. Although the increase in the latter half of 1914 was smaller than that in the earlier half, during the second, third and fourth quarters of 1915 and the first quarter of 1916 a sudden and abnormal rise occurred, and war marriages swelled the totals until they reached "record" heights. Thereafter the increase in marriages continued, but with diminished force, and by the third quarter of 1916 the number had fallen below the average. Crudely stated, he declared that the war has resulted in 200,000 people being married between August, 1914, and June, 1917, who in the ordinary course would not have married. The marriage rate for 1915 was the highest recorded, 19.4; the previous maximum, 17.9, was in 1853.

With reference to the marriage statistics in belligerent countries, he said that in Hungary the effect of the war had been that more than 600,000 people who in the ordinary course would have married had not done so. In Prussia, Bavaria, Saxony, Hesse, Hamburg and Bremen, six states containing more than 80 per cent. of the German population, the total number of marriages in 1913 was 434,103, and in 1914 the number was 392,053, a decrease of nearly 10 per cent., in spite of a great number of war marriages during the first month of the war. From figures available, in Saxony, compared with the last year of peace, the decrease was about 35 per cent., in Hamburg 24.5 per cent., in Bremen 37.6 per cent., and in Berlin 21.6 per cent., and he presumed that the decrease in the country was greater than in the town.

Comparing the statistics, the president said that the very notable difference was not difficult to account for. In Germany the whole population of military age was mobilized; in England war marriages were stimulated by generous allowances and pensions. On the introduction of compulsory service, larger numbers of men of marriageable age were fighting abroad, and the conditions were beginning to approach those of the Germans, the influence of which could be seen in the birth rate, although the comparison was wholly in favor of this country.

The loss of potential lives to the belligerent countries by the decrease in the numbers of children was, perhaps, the most important effect produced by the war on vital statistics. It was first felt at the end of April, 1915, and it would continue until nine months after the termination of hostilities and demobilization was more or less completed. In England and Wales, in the three years 1911-1913, the decrease in the births amounted to 4.2 per cent. in numbers as compared with 1908-1910, and represented a birth rate of 6.3. In Germany the decrease had been much more rapid of late years; the decline was 5 per cent. in numbers and 9 per cent. in rate, and in Hungary 1.1 and 3.5. From these figures it was apparent that the United Kingdom had suffered far less than had Germany in this vitally important point. The United Kingdom lost by the fall in births over 500,000 potential lives, approximately 10,000 per million of the population. Germany lost in the same period 2,600,000 approximately 40,000 per million. Hungary lost 1,500,000, approximately 40,000 per million. At the outbreak of war, the population of the central empires was about two and a half times as great as that of the United Kingdom; their losses of births had apparently been ten times as great. The poorer classes in this country had never experienced more favorable conditions, but the Germans, if all indications were to be believed, had suffered to such an extent as to affect seriously the general health of the population.

As regards infant mortality, the rate during 1914-1916 had been lower both in the United Kingdom and in Germany than in any previous period of like duration; but the summer mortality in 1917 appeared to have been extraordinarily high in several German cities in spite of the great organized efforts to save infant life, and the German rate all through remained at about 50 per cent. higher than in this country. The rate recorded in the United Kingdom in 1916 was the lowest on record. In speaking of the deaths during the period of the war, Sir Bernard Mallet distinguished between civilians and members of the armed forces. Generally there was a marked rise in civilian deaths in 1915, followed by a fall to below prewar numbers in 1916. One cause of the decrease was the restrictions in the output of alcoholic liquors.

FOOD CONTROL: BAN ON SALE OF CREAM

New orders have been issued by the food controller. The use of cream is prohibited except for the purpose of making butter or for consumption by invalids, young children, or other persons on a physician's order. The order has been issued to conserve as much full milk as possible, and because the use of cream has been chiefly a luxury.

Another order prohibits the use by brewers of any saccharin substance other than solid glucose or the invert or other product of low-grade sucrose polarizing not over 89 degrees, and from which not less than 40 per cent. of its weight has already been extracted in the form of grocery crystal sugar, honey, sugar or syrup. Brewers are, however, permitted to use their existing stocks or any sugar that was in transit to them, at the date of the order, from the manufacturers. The quantity of such saccharin substance that brewers are permitted to use is not more than 40 per cent. of the quantity used by them in the year 1915.

THE SURGICAL TREATMENT OF DISABLED MEN

In a lecture delivered at the Royal Institute of Public Health, Col. Sir Robert Jones, inspector of military orthopedics, said that wounded and disabled men form a serious proportion of the population, and must be helped to remain an economic part of the man power of the nation and not mere helpless dependents. Fully 50 per cent. of the wounded in this war suffered from injuries which either are or may become physical disabilities, the treatment of which is orthopedic. There are now a large number of orthopedic centers started or on the point of being started all over the country, providing accommodation for from 1,400 to 1,800 men each, completely equipped. They consist of special departments, each directed by specially trained surgeons. The heads of these departments hold consultations in doubtful cases. Sir Robert Jones defined orthopedics in relation to military surgery as the treatment by operation, by manipulation, by construction and by reeducation, of disabilities to arms and legs arising from injury or disease. The orthopedics of war he divided into preventive and corrective. Owing to the fact that most gunshot wounds are already septic when the wounded reach surgeons at the front, their energies are taxed by the effort to save life, and many patients reach England with various types of deformity and considerable shortening of the limb. The first duty of the orthopedic surgeon is to consider how the limb—a fractured thigh, for instance—may be lengthened, and lateral deflection, which produces almost complete loss of function of the limb in walking, remedied. When the patient has been made to walk with an apparatus that prevents fresh shortening of the limb, he is only improved, not cured; he is therefore retained in the orthopedic center until his joints become supple and his muscles are developed by intensive methods, including special forms of electric massage and exercises. Again, in the case of a stiff wrist or stiff elbow with, perhaps, loss of part of one of the bones of the forearm, the surgeon first mobilizes the joints, and then, if need be, grafts a piece of shin bone into the arm, the patient being kept in the hospital until the function of the arm is well on the way to restoration. In cases of nerve injury, it is necessary first to mobilize the joints and afterward to operate by nerve suture or tendon transplantation. In the case of a man with a helpless flail hand, certain muscles, which can be spared in the front of the forearm, are attached to paralyzed tendons; in three months the patient may be able to raise his hand. Another military orthopedic problem is to decide, when the elbow-joint, for instance, must be stiff, what is the best position in which to fix it. Usually a stiff elbow fixed at a suitable angle is better than a weak joint; but men engaged in certain trades find a movable though weak elbow more useful than a stiff joint. A great change in the morale of the men in orthopedic centers has been brought about by the progress of military orthopedics. At first they had grounds for fearing that if they accepted treatment designed for partial [illegible] complete restoration of function, their pensions would be reduced. Now the mental attitude of the patient is altered by the fact that pensions are based on physical disability without reference to earning power, and that there are penalties in the form of reductions if treatment is refused. Men are now open to the persuasion of the hospital staff and of cured comrades; they derive direct benefit, mental and physical, from curative workshops. The governing principle of curative work is that voluntary movements are of infinitely greater value than passive movements. When the vast installations of Zander instruments and the way they are employed are considered, Sir Robert Jones considers it amazing that more tragedies do not take place. One gentle movement in every direction of a stiff elbow might overcome adhesions; to repeat the movements in a machine only endangers the tissues by direct irritation. Exercises practiced in curative workshops are of two kinds, direct and indirect. The ingenuity of the instructor is shown in devising direct curative work suitable to each case; but the indirect method is often the best. For example, when a man with a stiff ankle is set to plane or saw wood, he unconsciously uses the ankle as he becomes interested in the work his hands are doing. Again, if a man with stiff fingers who cannot hold any tool is given something to do with the other hand, the crippled hand will come to the rescue in a difficulty and soon become useful. Owing to the control that surgeons at the front have obtained over gas gangrene and sepsis, the number of amputations is diminishing. Further expansion of orthopedic centers has been authorized with the object of getting patients directly from the front in order that the occurrence of deformity may be anticipated.

A man discharged from the army to civil life passes under the care of the Ministry of Pensions, which possesses great responsibilities and great powers for good. It cannot compel a pensioner to undergo training, but it can bring pressure to bear on him, for if treatment short of operation is refused, the pension is reduced, while bonuses are given to men who train, and, if they are married, a separate allowance. Many pensioners will require treatment for two or more years, but it can be carried on while they work or train. Patients discharged from orthopedic centers to civil life fall into two groups, Orthopedic A, consisting of the partially disabled who require further treatment of an orthopedic kind, and Orthopedic B, who require a certain amount of treatment of a general kind. The orthopedic centers supply to the first class a ticket giving a note of the patient's condition, with suggestions to the pension authorities as to the treatment required.

A Ten Months' Child: A Physician's Divorce Case

The old question of the possibility of ten months' gestation, and the consequent one of the legitimacy of a child when connubial intercourse last took place at the beginning of that period, have been fought out again in the law courts. The case is important because it brought to light the experience of our leading obstetricians on the point—a kind of up-to-date symposium. The petitioner, a captain in the Army Medical Corps, sought to divorce his wife on the grounds of adultery. The marriage took place, June 17, 1915. Neither he nor his wife desired to have children till the war was over. Dec. 19, 1915, they cohabited for the last time before he left for Egypt, but, the petitioner alleged, under circumstances that prevented pregnancy. The wife went to her brother in the country at a house where three officers were staying. Then she went to stay with some friend, and menstruated there. Jan. 19, 1916, she went to her father's house, and the suggestion was that between her stay at the last place and coming to her father she comitted adultery with an unknown man. March 10, 1916, she underwent an operation for appendicitis, when it was found that she was pregnant. March 20, she wrote to her husband informing him of the fact. He replied that her statement was absurd, that he was a physician and was convinced that nothing of the kind could ever have happened. Oct. 22, 1916, she gave birth to a child of normal period. Between her husband's leaving England and the birth of the child, 307 days elapsed. The following expert evidence was given for the husband: Dr. H. R. Spencer, obstetric physician to University College Hospital, said that he had known a case of gestation of 307 days from what he had been told was the last day of menstruation. He did not think that the husband in this case could possibly be the father. The operation could not have tended to prolong gestation. Dr. Griffith, obstetric physician to St. Bartholomew's Hospital, said that in protracted gestation the labor would be slow; but he admitted that he had known cases o ten months' children with normal delivery. For the respondent, Dr. Philips, obstetric physician to King's College Ho pital, said that he had experience of three cases, one of 298 days, the second of 306 days, and the third of 308 days, in each of which the husband had left the country for these periods. It was not impossible to have a ten months' child. In her evidence the petitioner said that her menstrual period ended December 18, and that she had proper intercourse with the petitioner, December 19. The judge (Mr. Justice Horridge) said that he believed the respondent, and that the case was one of protracted gestation. He therefore gave judgment in her favor.

Marriages

Charles Northmore Sturtevant, M.D., Frankford, Philadelphia, to Miss Martha Irvine of Mercersburg, Pa., at Frankford, December 8.

Lieut. Kenneth Allen Phelps, M. R. C., U. S. Army, West Point, N. Y., to Miss Ora Shaffner of Burlington, N. C., December 5.

Lieut. Emery Bowers Neff, M. C., U. S. Army, Fort Ringgold, Texas, to Miss Ruth Heath of Houston, Texas, November 27.

Lieut. Samuel L. Wadley, M. R. C., U. S. Army, to Miss Bertha Elizabeth Rahm, both of Memphis, Tenn., December 5.

Marvin H. Porterfield, M.D., Martinsburg, W. Va., to Miss Catherine E. MacLuckie of Frostburg, Md., November 6.

S. Murray Houtz, M.D., to Mrs. Grace M. Moist, both of West Berwick, Pa., at Beach Haven, Pa., October 23.

Henry Ernest Ricketts, M.D., Belleville, N. J., to Miss Mary T. McCue of Newark, N. J., November 17.

Francis Stephen Caldicott, M.D., Woburn, Mass., to Miss Helena Stanfield of Louisville, Ky., recently.

Samuel Duncan Cameron, M.D., to Miss Laura Brouillard, both of North Yakima, Wash., October 25.

Smith Ely Jelliffe, M.D., to Miss Bee Dobson, both of New York City, December 3.

George Cresswell Davis, M.D., to Miss Nelle Bound, both of Milton, Pa., December 1.

Jesse Carroll Coggins, M.D., to Miss Mabel McCahan, both of Baltimore, December 8.

James A. Kiernan, M.D., Chicago, to Miss Grace Cole of Alton, Ill., December 10.

Deaths

Everett James McKnight, M.D., a member of the Board of Trustees of the American Medical Association, died suddenly at his home in Hartford, Conn., December 25, from angina pectoris. Dr. McKnight was born June 12, 1855, in Ellington, Conn., and was graduated from Yale University with the degree of A.B. in the class of 1876. After a year of study in Yale Medical School he entered the College of Physicians and Surgeons in the City of New York, from which he was graduated in 1879. Since that time he has practiced in Hartford and East Hartford, specializing in surgery, and at the time of his death was in active service on the staff of the Hartford Hospital. He was an enthusiastic Yale man, and made the arrangements for the first intercollegiate football game between Yale and Harvard. His alma mater gave him the degree of A.M. in 1907. He served as president of the Connecticut State Medical Society in 1907-1908, and of the Hartford Medical Society in 1914. He represented the town of East Hartford in the General Assembly in 1893, and was chairman of the committees on fisheries and public health.

His official connection with the American Medical Association commenced in 1908, when he was elected a member of the House of Delegates and continued until his election to the Board of Trustees in 1916. His last official work for the Association was as a member of the War Committee, regarding the appointment of advisory boards for the new selective draft.

One of his associates pays him this tribute: "We all put work on him, from the government down to his humblest friend, because he was so capable; then we put more work on him because he was so willing. He worked for others until the last minute." Dr. McKnight was an earnest and conscientious worker, with a humanitarian interest in his fellow men. When he gave himself to a cause he labored with complete devotion to its accomplishment.

Edward Mathew Hanson, M.D., Keokuk, Iowa; Keokuk (Iowa) Medical College, 1892; aged 49; a Fellow of the American Medical Association, and a specialist on diseases of the eye, ear, nose and throat; professor of electrotherapeutics in Keokuk Medical College of Physicians and Surgeons; eye, ear, nose and throat surgeon to Graham Hospital, Keokuk; who had been suffering from a nervous breakdown; died at the home of his cousin in St. Louis, December 11, from the effects of carbolic acid, self-administered, it is believed, with suicidal intent.

Charles H. North, M.D., Dannemora, N. Y.; University of Buffalo, N. Y., 1898; aged 49; a member of the Medical Society of the State of New York, and American Medico-Psychological Association; who entered the state service after graduation as assistant physician at the Matteawan Hospital for Insane Criminals, was transferred to the Dannemora State Hospital for Insane Felons, on its opening in 1900, and was made superintendent of the institution in 1904; was stabbed and almost instantly killed by an insane inmate, December 12.

Capt. Zotique Rousseau, M. R. C., U. S. Army, Troy, N. Y.; Laval University, Quebec, 1869; aged 71; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of New York, and for several terms president of the Rensselaer County Medical Society; on duty at Watervliet Arsenal; for more than forty years attending physician at the Troy Hospital; physician to the Home of the Aged Poor, and for the House of the Good Shepherd; died at his home, December 6, from pneumonia.

Jesse Snodgrass, M.D., Kenton, Ohio; Bellevue Hospital Medical College, 1867; aged 77; formerly a Fellow of the American Medical Association; a member and once assistant secretary of the Ohio State Medical Association; at one time president of the Northwestern Ohio Medical Association; a specialist on diseases of the eye, ear, nose and throat; assistant surgeon of the Eighth Tennessee Volunteer Infantry during the Civil War; who underwent operation several months ago, died at his home, December 8.

Orran George Cilley, M.D., Boston; Dartmouth Medical School, Hanover, N. H., 1868; aged 77; for several years coroner; from 1873 to 1879, surgeon of the First Squadron Cavalry, M. V. M.; surgeon-general of Massachusetts in 1883, under Governor Benjamin F. Butler; for four years physician to the Charles Street Jail; died at his home, December 9.

Albert Stone Gray, M.D., Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1887; College of Physicians and Surgeons, Chicago, 1889; aged 53; for several years a contributor of articles on health topics to the daily press; died in St. Luke's Hospital, Chicago, December 17, from anemia.

John Royer Laughlin, M.D., Hagerstown, Md.; George Washington University, Washington, D. C., 1906; aged 45; formerly a Fellow of the American Medical Association; a member of the Medical and Chirurgical Faculty of Maryland; died in Hallendale, Fla., December 14, from arteriosclerosis.

Charles Francis House, M.D., Painesville, Ohio; Long Island College Hospital, Brooklyn, 1874; aged 69; formerly a Fellow of the American Medical Association; for several terms president of the Lake County (Ohio) Medical Society; died at his home, December 12, from a nervous breakdown.

Charles S. Payne, M.D., Liberty, N. Y.; University of Buffalo, N. Y., 1884; aged 57; formerly a Fellow of the American Medical Association; a member of the Medical Society of the State of New York; died at his home, December 12, from cerebral hemorrhage.

Amos H. Helm, M.D., New Providence, Pa.; Jefferson Medical College, 1868; aged 72; a member of the Medical Society of the State of Pennsylvania; for forty years a school director; died suddenly from heart disease, December 10, while shoveling snow in his yard.

Andrew W. Tracy, M.D., Meriden, Conn.; McGill University, Montreal, 1873; aged 71; a member of the Connecticut State Medical Society; mayor of Meriden in 1892, and a member of the city council for two terms; died at his home, December 10.

Guido L. Stempel, Macedonia, Iowa (license, Iowa, years of practice, 1886); aged 82; formerly a member of the Iowa State Medical Society; a well known naturalist and collector of birds and butterflies; died at his home, December 13, from nephritis.

R. M. Montgomery, M.D., Hazlehurst, Ga.; Medical College of the State of South Carolina, Charleston, 1897; aged 52; a member of the Medical Association of Georgia; died in a sanatorium in Hazlehurst, December 2, from acute gastritis.

John Heard Ford, M.D., Vinton, La.; Louisville (Ky.) Medical College, 1893; aged 48; a member of the Louisiana State Medical Association; died at his home, August 2, from tumor of the brain, four weeks after a surgical operation.

Murdoch Chisholm, M.D., Halifax, N. S.; McGill University, Montreal, 1879; L.R.C.P. (Lond.), 1886; professor of clinical surgery in Dalhousie University, Halifax; was killed in the explosion which devastated Halifax, December 6.

Simon Elston Hooper, M.D., West Branch, Mich.; Western University, London, Ont., 1890; aged 54; a Fellow of the American Medical Association; died at his home, November 30, from septicemia, due, it is said, to pyorrhea.

John P. Logan, Dewitt, Mo. (license, Missouri, 1883); aged 63; for forty-two years a practitioner; formerly a member of the Missouri State Medical Association; died in St. Joseph's Hospital, Kansas City, December 4.

Albert Leroy Ward, M.D., Bement, Ill.; Chicago Homeopathic Medical College, 1899; aged 47; formerly a member of the Illinois State Medical Society; died in Decatur, Ill., September 21, from typhoid fever.

Richard Wallopie Kent, M.D., San Francisco; New York University, New York City, 1886; surgeon in the Pacific Mail Steamship Company's service; died in Calcutta, India, September 30.

Andrew Kamerling, M.D., Buffalo; University of Buffalo, 1866; aged 78; formerly a member of the Medical Society of the State of New York; died at his home, about December 6.

Adelaide Lambert, M.D., New Haven, Conn.; Boston University School of Medicine, 1884; aged 64; a member of the Connecticut State Medical Society; died recently at her home.

James Henry Knight, M.D., Morgantown, Ind.; Bellevue Hospital Medical College, 1875; formerly an assistant surgeon in the United States Army; died at his home, December 4.

Anseel McKinstry Whitbeck, M.D., Brooklyn; aged 81; a practitioner since 1859; died at the home of his daughter in Brooklyn, December 4, from senile debility.

William Caldwell Stevens, M.D., Worcester, Mass.; Harvard Medical School, 1883; aged 62; a Fellow of the Massachusetts Medical Society; died at his home, October 17.

S. A. Reasons, M.D., Waldo, Ark.; Memphis (Tenn.) Hospital Medical College, 1894; aged 49; also a druggist; died in a hospital in Little Rock, Ark., December 5.

Samuel Hastings Brown, M.D., Philadelphia; Hahnemann Medical College, Philadelphia, 1869; aged 72; died at his home, November 21, from cerebral hemorrhage.

Frank Marion Foote, M.D., Marshall, Mich.; University of Michigan, Ann Arbor, 1884; aged 56; died at his home, October 28, from pulmonary tuberculosis.

Frank B. Black, M.D., Gilboa, Ohio; Eclectic Medical Institute, Cincinnati, 1886; aged 65; died in a hospital in Cincinnati, December 5, from typhoid fever.

John Calvin Cummings, M.D., Harrisburg, Pa.; University of Maryland, Baltimore, 1884; aged 63; died at his home, November 6, from cerebral hemorrhage.

Joseph H. Matthews, M.D., Lollie, Ark.; University of Arkansas, Little Rock, 1893; aged 48; died at the home of his niece in Conway, Ark., December 6.

B. F. Zeller, M.D., Union City, Ind.; Medical College of Ohio, Cincinnati, 1875; aged 72; a veteran of the Civil War; died at his home, November 29.

John A. Blaydes, M.D., Hot Springs, Ark.; Transylvania University, Lexington, Ky., 1857; aged 83; died at his home, August 18, from pneumonia.

William H. King, M.D., Derry, Pa.; Jefferson Medical College, 1870; aged 68; died in the Columbia Hospital, Wilkinsburg, Pa., December 5.

Wilbur F. Curtis, M.D., Chicago; Bennett Medical College, Chicago, 1890; aged 63; died at his home, December 9, from heart disease.

Lewis A. Lee, M.D., Conyers, Ga.; Atlanta (Ga.) Medical College, 1878; aged 60; died in a sanatorium in Atlanta, December 5.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

NOSTRUMS IN RETROSPECT

A Review of Worthless or Unscientific Proprietary Mixtures Previously Criticized

[Foreword.—The article that follows is the third[1] of a series written primarily for the purpose of reviewing the findings of the Council on Pharmacy and Chemistry on certain unscientific or worthless proprietary mixtures. Although the preparations which will be taken up in this series have been extensively dealt with in previous reports, the fact that they are still widely advertised and sold indicates the need of further publicity. The series is written by a man who is thoroughly conversant with the work of the Council on Pharmacy and Chemistry and can speak authoritatively on questions dealing with the actions of drugs in the treatment of disease.]

[Article III]

PEPTO-MANGAN

S. Q. Lapius, M.D.

It would be interesting, and even instructive, to know how many educated physicians, if any, are now prescribing Pepto-Mangan (Gude): Interesting as indicating the number who have neglected to avail themselves of the work of the Council on Pharmacy and Chemistry, especially the earlier work; instructive in that it would show how many are still prescribing by the rule of thumb, and who are taking their therapeutic instructions from purely commercial sources instead of striving to learn how to choose those drugs that are most effective in the treatment of disease.

It has been pointed out many times in the pages of The Journal that many nostrums are advertised first to physicians, and that after physicians have served as the unpaid agents of the manufacturers in introducing the preparations, their exploitation is then commonly continued by means of advertisements in the public press. This plan has been followed successfully in so many cases that we have now come to look on it as the regular course. It is in keeping with this rule that we find Pepto-Mangan now advertised in the public press, the physician having served the manufacturer's purpose.

DISCARDED THEORIES OF IRON MEDICATION

It will be recalled that many years ago the theory was held that hydrogen sulphid (sulphuretted hydrogen) interfered with the absorption of the iron of the food, and that the administration of medicinal iron prevented this interference by neutralizing the hydrogen sulphid (sulphuretted hydrogen). It was only a short step to argue that manganese might replace the medicinal iron in combining with the hydrogen sulphid, permitting the food iron to be absorbed, and it was held that only food iron could be utilized in the formation of hemoglobin.

It is hardly necessary to remind the reader that this theory rests on numerous fallacies. There is no hydrogen sulphid worth mentioning in the small intestine where iron is absorbed; food-iron cannot be utilized directly in the formation of hemoglobin but must be broken into simple forms for absorption; and, further, inorganic iron, such as ferrous carbonate, serves the purpose admirably where iron is indicated. With the acceptance of these well-established facts all possible excuse for the therapeutic employment of Pepto-Mangan in place of iron vanished, but as plain and simple as this fact is, the unnecessary and expensive Pepto-Mangan continues to be prescribed by physicians who will not take the slight trouble to investigate the claims for this nostrum.

---

FALSE AND MISLEADING CLAIMS

That there is not merely a difference of opinion on the part of the exploiters and the Council, but that actual misrepresentation has been employed in the exploitation of this nostrum to physicians has been shown on more than one occasion. About twelve years ago the M. J. Breitenbach Company, the proprietors of Pepto-Mangan, claimed that the report of the Commission that had been appointed for the investigation of anemia in Porto Rico "would alone suffice to establish Pepto-Mangan at once as the foremost hematinic known." Examination of the report showed that the Commission made no such claims; on the contrary the Commission protested against this misrepresentation. (THE JOURNAL A. M. A., Oct. 7, 1905, p. 1099.)

M. J. BREITENBACH COMPANY
New York, U. S. A.

From the *New York Medical Journal.*

Undaunted by this exposure of their methods, the Breitenbach Company later sent out a statement of results purporting to have been obtained by one Mateo M. Gillen, in the treatment of infantile anemia on Randall's Island in New York City. At the instance of THE JOURNAL the hospital records in these cases were examined, and it was found that the pretended report was little more than a tissue of falsehood. (THE JOURNAL A. M. A., April 6, 1907, p. 1197.)

About two years ago the Council reported that while the statements just referred to were no longer made, they had never been definitely admitted by the Breitenbach Company to be erroneous, and that Pepto-Mangan was then being exploited to the public indirectly. (Council Reports, 1914, p. 121.)

We reproduce an advertisement that has been appearing weekly in the *New York Medical Journal* for several months. One can only suppose that this advertisement was intended to mislead physicians, and it would be an insult to the intelligence of the average reader to attempt any detailed discussion of it, but enough has been said to show how misleading the statements are. One should note particularly the advice—old as the nostrum business itself—contained in the advertisement, to prescribe an original bottle. The reason for such advice is simple. Experience has shown that when original bottles are dispensed patients soon learn to buy the nostrum without consulting the physician, for they shrewdly suspect that he knows *no more about the preparation than* they, and that he gets his information from precisely the same sources that are available to them. They are obviously right. In truth, the physician who prescribes Pepto-Mangan as a hematinic shows ignorance of the most rudimentary facts of iron therapy, and the intelligent patient soon perceives his limitations.

THE PROBLEM OF IRON THERAPY

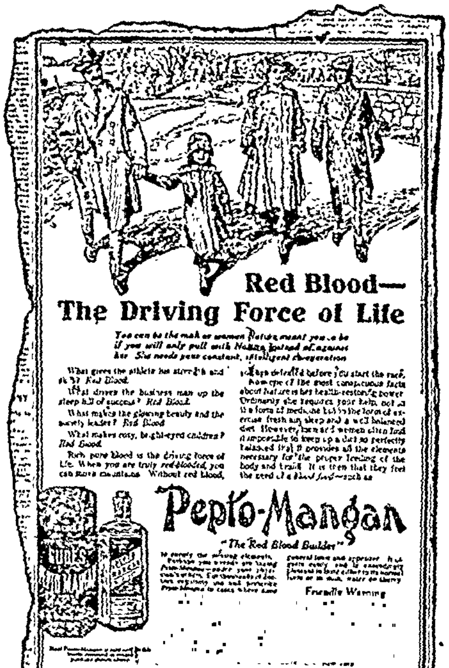
The investigation of the problems of iron therapy and its utilization in the formation of hemoglobin forms one of the most brilliant chapters in pharmacologic research, and there is no better established fact in therapeutics than that any organic or inorganic preparation of iron that does not irritate the stomach may be employed effectively when the administration of iron is indicated. "Useful Drugs" contains a list of iron preparations that are suitable for all conditions which call for iron, and the clinician may rest assured that he will never have occasion to go outside of that list to prescribe any substitute.

As a matter of fact, it seems probable that the very number of available iron preparations has served to cause confusion, thus affording an opportunity for the nostrum maker to introduce his superfluous compounds. It may be difficult at times to select the preparation of iron best suited to the individual patient and it is this difficulty that has led the clinician to *listen to the seductive claims made for the various pretended* substitutes for iron. One should approach the question of choosing the proper form of iron for therapeutic use with the recognition of the fact that there is no such thing as a substitute for iron in the formation of hemoglobin, that there are no ideal forms of iron other than those found in the foodstuffs. Further, the clinician cannot avoid the disadvantages inherent *in all forms* of iron that he can prescribe, and he must therefore seek that which seems best suited for the individual patient.

Bunge estimated the amounts of iron present in various foods and a table based on this, and other data, is given in "Pharmacology of Useful Drugs" (published by the American Medical Association). Ordinary foods in an ample diet contain enough iron to supply the normal daily loss, which amounts to only a few milligrams, but many persons who have poor appetites take an insufficient amount of iron in their food and become anemic. In such cases the additional iron required can be supplied best by adding spinach, eggs, apples, or other iron-rich food to the dietary.

SOME IRON COMBINATIONS

William Hunter discusses the subject of anemia and its treatment at considerable length in the "Index of Treatment," Ed. 6, pp. 17-37, and gives many prescriptions containing iron for use under different conditions, and while it is unnecessary to reproduce all of these here, a few may be given in order to suggest suitable methods of prescribing iron when it cannot be given in sufficient amounts in the food.



Red Blood—
The Driving Force of Life

You can be the man or woman Nature meant you to be if you will only pull with Nature instead of against her. She needs your constant, intelligent cooperation.

What gives the athlete his strength and skill? *Red Blood.*

What drives the business man up the steep hill of success? *Red Blood.*

What makes the glowing beauty and the society leader? *Red Blood.*

What makes rosy, bright-eyed children? *Red Blood.*

Rich pure blood is the *driving* force of life. When you are truly *red-blooded*, you can move mountains. Without red blood, you are defeated before you start the race.

One of the most conspicuous facts about Nature is her health-restoring power. Ordinarily she requires your help, not in the form of medicine but in the form of exercise, fresh air, sleep and a well balanced diet. However, men and women often find it impossible to keep up a diet so perfectly balanced that it provides all the elements necessary for the proper feeding of the body and brain. It is then that they feel the need of a *blood food*—such as

Pepto-Mangan
"The Red Blood Builder"

Friendly Warning

A newspaper advertisement of Pepto-Mangan.

In chlorosis Hunter advises that that form of iron which experience has shown to be least disturbing to the patient's stomach should be used, and he suggests separate stomachic mixtures to be used simultaneously not mixed with the iron itself. Where constipation exists—and this is a very common accompaniment of chlorosis—he gives the following aperient iron combination:

Ferrous sulphate	gr. iv
Magnesium sulphate	ʒ i
Aromatic sulphuric acid	♏ vii
Tincture of ginger	♏ x
Compound infusion of gentian (B. P.) q. s., ad	℥ i

This, constituting a single dose, is to be taken twice daily—at 11 a. m. and 6 p. m. A little compound tincture of gentian and water may be used in place of the compound infusion of the British Pharmacopeia. He modifies this somewhat as occasion demands by using sodium sulphate and adding bicarbonate of sodium (which converts the sulphate of iron into ferrous carbonate) and adds 10 minims of spirit of chloroform to act as a stomachic.

Hunter also suggests the use of pills of aloes and iron in place of the above mixture, and when constipation has been corrected the aloes may be omitted and the pill of ferrous carbonate alone may be used for the iron. Hunter's comment regarding this pill is: "very satisfactory."

The same form of iron is available in the compound iron mixture, formerly official, which Hunter says is exceedingly good. In this country the compound solution of iron and ammonium acetate, Basham's mixture, so called, has long enjoyed a wide reputation as causing very little disturbance of the stomach, and the homely tincture of ferric chlorid is probably useful in a large majority of cases in which the stomach is not especially irritable.

We may say with assurance that one of the forms suggested here will suffice for practically every case in which it is necessary to reinforce the amount of iron available in the food by some pharmaceutical preparation. If these do not satisfy your requirements consult a really competent pharmacist and enlist his aid in devising a mixture especially suited to your individual patient.

Correspondence

THE ROENTGEN RAY IN TREATMENT OF EPILEPTIC SUBJECTS OF STATUS LYMPHATICUS

To the Editor:—In Bellevue Hospital the diagnosis of status lymphaticus by simple inspection of the body is frequently made, both in the wards and in the necropsy room—in the latter place without the clinical history and before proceeding with the systematic examination of the viscera. In the male, the configuration of the body in status lymphaticus is of the female type—the face is beardless or nearly so, and the axillary and other hairs are scanty, the skin is smooth and of an unusually delicate texture, the pubic hairs are sharply defined in a transverse direction, the waist is slender and sloping, and the thighs are gracefully arched both laterally and anteriorly. In the female, the diagnosis is rather more difficult, and rests largely on features that are only an accentuation of those normally encountered, namely, the thin, delicate skin, the narrow waist and the arched thighs, together with the small axillary pads and the scanty growth of hair on them.

In the psychopathic pavilion at Bellevue Hospital, it has been noted by Dr. Karpas that many epileptics present the external peculiarities of status lymphaticus; and it is a well known clinical fact that epileptic seizures not uncommonly cease at or about the age of puberty, in other words, at a period when the thymus undergoes involution. Ohlmacher has pointed out the resemblance between epileptic seizures and the symptoms that sometimes precede sudden death in subjects of status lymphaticus. In the pathologic laboratories at Bellevue Hospital I have often had occasion to observe the presence of myriads of acute necroses in the lymphoid tissues in subjects suddenly dead with all the physical attributes of status lymphaticus, and have advanced the theory (*American Journal of Diseases of Children*, 1917, **14,** 463) that these necroses represent the structural expression of sensitization of the tissues to toxic nucleoproteins, and that the convulsive seizures in certain epileptics and sudden death in other subjects of status lymphaticus are of the nature of anaphylactic phenomena.

I should appreciate an opportunity, through the medium of The Journal, to direct the attention of radiologists to these facts and to suggest that epileptics with the external configuration of status lymphaticus be systematically subjected to radiation, particularly in the region of the thymus, the spleen and the intestine. The several groups of superficial lymph nodes are not commonly enlarged in status lymphaticus, and are apparently negligible from this standpoint.

It is of interest to observe that many soldiers, exposed to the terrifying vicissitudes of trench life, have been invalided to France and England with symptoms of exophthalmic goiter varying in intensity from simple tremor and tachycardia to the fully developed picture; that almost every subject of exophthalmic goiter examined postmortem reveals hyperplasia and persistence of the thymus, together with the other anatomic features of status lymphaticus, and, finally, that the British radiologists have reported remarkable results in exophthalmic goiter in returned soldiers who have been exposed to radiation of the thyroid gland (White, C. P., and Hernaman-Johnson, F.: *Lancet*, London, 1916, **1,** 78. Stoney, F. A.: Ibid., 1916, **1,** 777). In these circumstances it is possible, I think, that the anatomically related thymus has come in for a share of radiation, and that improvement is to be traced partly to this effect.

At all events, the use of the roentgen ray is known to discourage the proliferation of lymphoid tissues, and its employment in epileptic subjects of status lymphaticus appears to be a procedure justified by anatomic considerations.

Douglas Symmers, M.D., New York.
Assistant Director of Laboratories, Bellevue and Allied Hospitals.

CHARCOT'S OPINION AND CRITICISM OF GERMAN MEDICINE

To the Editor:—Ten years after Sedan and thirty-three before the present war, the great French physician Charcot in his "Lectures on Senile Diseases," page 20, indulges in comment on French, German and English medicine that is perhaps more striking now than when it was written. It will probably be interesting to the 20,000 physicians who have already volunteered in the medical service of our country.

The pride of the Frenchman in Laennec and the stethoscope is evident. The slow waking up of the German to modern scientific medicine, and the influence of Schönlein, of purpura fame, and of Rokitansky is charmingly described. The keen terseness of the French is evident when he refers to "the science from beyond the Rhine." In the last two paragraphs he accuses Virchow of abusing "the word science in order to excite German minds for the sake of a narrow patriotism." His contrast of "the exclusive and illiberal ideas of the Prussian savant" with "the grand words of one of England's greatest physicians" is striking. The Englishman is Graves, of exophthalmic goiter fame. My copy of Charcot was issued by the New Sydenham Society in 1881, translation by Tuke.

"But, some will say, what use are these big words and grand ideas? Have the scientific tendencies about which you make so much fuss had a beneficial influence on the practice of the art? Do you cure more patients than they cured of old? These, gentlemen, are very indiscreet questions, and might easily be thrown back at our adversaries. Let it suffice to reply, with an honored teacher, that art without science is not slow to degenerate into routine [Béhier]. That hackneyed skepticism, which people so willingly oppose to all progress of the human mind, is a comfortable pillow for lazy heads; but the period in which we live allows no time for falling asleep.

"To put in its true light the happy influence which scientific tendencies may have on the advance of medicine, I need only recall to you the remarkable transformation which in the course of the last twenty years this science has undergone in a neighboring country to ours, in Germany. Let us transport ourselves a moment across the frontier, and go back in thought toward the year 1830. At that time Schelling and his audacious 'Philosophy of Nature' reigned absolute masters over German minds. The fashion was for poetic points of view and transcendental conceptions, while a physician allowed himself in a treatise on mucous fever seriously to compare a blood corpuscle to the terrestrial globe, because both are round, flattened at the poles, and possess a central nucleus surrounded by an atmosphere [H. Horn].

"During this time medicine was thus reduced to a deplorable condition. Although they possessed translations of the chief pathological works recently published in France and England, yet the progress long accomplished in these two countries remained as though it had never taken place, for none of them understood its importance. An accurate local diagnosis was never made either in hospital or in private practice. In more than one German university the stethoscope was almost unknown; if anybody happened to come across one of these instruments he examined it with a sort of infantile curiosity, or received with unfavorable jokes those eccentric individuals who, by means of this bit of wood, professed to hear unheard of things. Besides, most chest and heart diseases, as well as chronic skin affections, formed an almost unexplored territory. And when they began to talk of the French it was only to ridicule, this time with more show of justice, the curious mania which made them look on all diseases as inflammations [Wunderlich].

"Things remained thus till near 1840. Then began the work of regeneration (chiefly through Schönlein's influence) by the introduction of the French methods into clinical work. Then it was the turn of morbid anatomy, brilliantly represented at Vienna by Rokitansky. But already Müller had appeared in physiology, and soon created morbid histology, which was long to remain an almost exclusively German science.

"Gentlemen, you know the rest. The German universities presented the spectacle, new to them, of an unheard of, almost feverish, activity; and you are not ignorant that this fever for work, which does not yet seem near extinction, has already produced more than one work of fundamental importance.

"For more than ten years this great intellectual movement remained almost unnoticed in France. From time to time some foreseeing observer tried to draw public attention to it; but there was general indifference to struggle against, and, whilst everything was astir in Germany, we in France were occupied with other matters. At last the day has come, and it is understood that a great power has arisen in our vicinity, so that we shall have in future to reckon with the science from beyond the Rhine. [This lecture was given in 1867.]

"By a very natural reaction people soon got to think extravagantly of the tendencies they had at first opposed; and whilst in France we are perhaps too much inclined nowadays to think nothing of other than German work, our neighbors, drunk with success, seem persuaded that for the future the empire of Science belongs to them. Gentlemen, we must know how to allow something to the inebriation of such a triumph. Yet it is not without regret that we have recently seen an eminent man confound the rights conferred on him by his high position as a savant with the political mandate entrusted to his charge by the electors of Berlin, and abuse the word science in order to excite German minds for the sake of a narrow patriotism [in allusion to a discourse of Virchow's at the Congress of German Naturalists, September, 1865]. Nobody should forget that science owns no country and is the property of no race. With the exclusive and illiberal ideas of the Prussian savant, we will contrast the grand words of one of England's greatest physicians [Graves].

"'The empire of reason, extending from the old to the new world, from Europe to the antipodes, has encircled the earth; the sun never sets on her dominions—individuals must rest, but the collective intelligence of the species never sleeps.'"

Major, M. R. C.

Relations Between Cancer and Diabetes.—An exchange quotes an article by H. Strauss in the *Deutsche medizinische Wochenschrift*, No. 39, to the effect that among 140 diabetic patients he found a history of cancer in the mother in sixteen and in the father in three. This seems to suggest, he says, that cancer in the parents predisposes to diabetes.

Wyoming: Laramie, Feb. 6-8. Sec., Dr. H. E. McCallum, Laramie.

Minnesota August and October Examinations

Dr. Thomas McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral, practical and written examinations held at Minneapolis, Aug. 22-24 and Oct. 2-4, 1917. The examinations covered 18 subjects and included 80 questions. An average of 75 per cent. was required to pass. Eleven candidates were examined, all of whom passed. Eight candidates were licensed through reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, Chicago	(1896)	76
Indiana University	(1917)	87
Johns Hopkins University (1914) 89; (1916) 88, 93;	(1917)	84, 88
Harvard University (1913) 90;	(1917)	88
University of Michigan Medical School	(1904)	78
University of Minnesota	(1918*)	85

College LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
College of Physicians and Surgeons, Chicago	(1900)	Iowa
Hahnemann Medical Coll. and Hospital of Chicago	(1906)	Illinois
Northwestern University	(1914)	S. Dakota
Tulane University of Louisiana	(1910)	Louisiana
St. Louis University	(1915)	Missouri
Cincinnati College of Medicine and Surgery	(1877)	Ohio
Marquette University	(1915,2)	Wisconsin

* A year's internship in an approved hospital is required for graduation from the University of Minnesota Medical School, but only completion of a four-year medical course is required for licensure in Minnesota.

North Dakota July Examination

Dr. G. M. Williamson, secretary of the North Dakota State Board of Medical Examiners, reports the oral, practical and written examination held at Grand Forks, July 3-6, 1917. The examination covered 13 subjects and included 110 questions. An average of 75 per cent. was required to pass. Of the 3 candidates examined, 2 passed and 1 failed. Seven candidates were licensed through reciprocity. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1916)	77.5
University of Minnesota	(1916)	80.5
FAILED		
University of Michigan Medical School	(1911)	68.8

Book Notices

ELEMENTS OF FIELD HYGIENE AND SANITATION. By Joseph H. Ford, B.S., A.M., M.D., Colonel, Medical Corps, U. S. Army. Approved for Publication by the Surgeon-General, U. S. Army. Cloth. Price, $1.25 net. Pp. 248, with 152 illustrations. *Philadelphia: P. Blakiston's Son & Co., 1917.*

This manual, which is one of the many approved for publication by the Surgeon-General, concerns the principles involved in keeping troops healthy. After a brief introductory chapter, the author discusses personal hygiene, the march, camps, water, the mess, camp diseases, and illustrative regulations. The section on personal hygiene is modern in its point of view, giving special attention, as do all of the chapters, to the experiences of Pershing's expedition into Mexico and of the warring nations abroad in the present war. Perhaps a little too much space is devoted to the numerous methods for getting rid of lice, some six or eight methods being described, which would seem to indicate that none is satisfactory. The section devoted to the march is quite brief, but every sentence is practical and important. The most extensive portion of the book is that devoted to the camp. This is fully illustrated by pictures and diagrams of actual camps in various expeditions, and it takes up questions of choice of camp sites, shelter, disposal of waste, care of foodstuffs, bathing facilities, latrines, incinerators, etc. The chapter on camp diseases is also brief but accurate and practical. The book is based largely on methods practiced in our own Army, and frequent reference is made to special orders and regulations that have been issued at various times by the Surgeon-General's Office. The officer who studies this book and supplements his knowledge by securing the regulations referred to will find himself excellently equipped for rendering his duties satisfactorily.

DISEASES OF THE CHEST AND THE PRINCIPLES OF PHYSICAL DIAGNOSIS. By George William Norris, A.B., M.D., Assistant Professor of Medicine in the University of Pennsylvania, and Henry R. M. Landis, A.B., M.D., Assistant Professor of Medicine in the University of Pennsylvania. With a Chapter on the Electrocardiograph in Heart Disease by Edward B. Krumbhaar, Ph.D., M.D., Assistant Professor of Research Medicine in the University of Pennsylvania. Cloth. Price, $7 net. Pp. 782, with 413 illustrations. Philadelphia: W. B. Saunders Company, 1917.

In the first 250 pages, the examination of the lungs and the examination of the circulatory system are considered. The principles underlying physical examination are especially emphasized. Technic and interpretation of signs are also clearly set forth. The third part (pp. 257-759) is taken up with the clinical features of chest diseases. The topics are treated briefly, with emphasis laid on physical signs and the underlying morbid anatomy. The subject of treatment is omitted. The especial feature of the work is the stress placed on the principles underlying physical diagnosis. To this end diagrams, drawings and photographs illustrating normal and pathologic anatomy are fully utilized. Most of these are of surpassing excellence. Those of frozen sections are wonderfully instructive, and if carefully studied will be of material help to student or practitioner in clearing up the meaning of physical signs that otherwise he might accept solely on authority. Krumbhaar has a brief but good chapter on the electrocardiograph. We might wish that the roentgen ray as a means of diagnosis had received a little fuller consideration. And we wish that some one would explain why the unclosed septum of the ventricles in congenital heart disease is so often called "imperforate," as it is by our authors. Are we wrong in thinking it is a plain misuse of the term? One might question the advisability of making a classroom textbook of this work for beginners in the study of physical diagnosis. But for the more advanced student, the hospital intern, or the practitioner who desires to perfect himself in this art, it should be a most stimulating and helpful book.

Medicolegal

Cannot Pay Experts for Examining Defendants

(State vs. Weeks (N. H.), 101 Atl. R. 35)

The Supreme Court of New Hampshire, in overruling exceptions to an order disallowing a claim against the county for the fees of experts employed to examine the defendant, who was indicted for murder and the defense of insanity suggested, says that the case appeared to be one of new impression. No precedent has been found for the course here urged in behalf of the defendant; the proposition being that the public should pay the expenses incurred by the defendant outside of court in the preparation of his defense. Of course there can be no common-law authority for such an order. It required legislative action to give the defendant the rights he would have in a civil cause. It is manifest that a right so acquired cannot be extended so as to include a privilege or right never known to the common law, and in no way created by any statute. The statute governing the rights of persons charged with the more serious crimes was revised in 1901, and again amended in 1907. The subject has evidently received careful legislative consideration, and there is nothing in any of the statutes which have been enacted which gives color to the idea that authority has been conferred to charge the public with the expenses incurred by the defendant in preparing for trial, except so far as counsel fees and those for travel and attendance of witnesses are concerned. It was urged by the state in argument that the statute providing that "all legal costs attending the arrest, examination, or conveyance of an offender, except when directed or approved in writing by the counsel of the state, or county commissioners, shall be paid by the complainant" was applicable to this claim, and that it must be disallowed because its incurrence had not been previously authorized by the state's counsel. But that statute has no application to the claim here presented. It relates solely to expenses incurred in prosecutions for alleged crimes, and has nothing to do with the regulation of allowances to or on behalf of defendants. The state's contention that the court has no power to allow this claim is sound. But the reason for this result is that no such authority has been conferred on the court, and not that the consent of the state's counsel is essential.

Misbranding of a "Remedy"

(Simpson vs. United States (U. S.), 241 Fed. R. 841)

The United States Circuit Court of Appeals, Sixth Circuit, affirms a conviction of defendant Simpson of violating the Food and Drugs Act as amended in 1912 by the interstate shipment of certain drugs alleged to have been misbranded in that the label of the carton or package containing the drug, as well as a circular therein, contained false and fraudulent statements regarding the curative or therapeutic effect of the drugs. The court says, among other things, that the information charged that the shipment was made by the defendant "trading as Dr. C. M. Simpson's Medical Institute," and that the name of the article given on the label of the carton was "Dr. C. M. Simpson's Cerebro-Spinal Nerve Compound." The natural construction would be that it was the defendant whose knowledge and reckless and wanton disregard of the truth was intended to be charged. The court also thinks the information should fairly be interpreted to mean that the misrepresentations were intended to accompany the bottles into the hands of the consumers. It alleged that the shipment consisted of "certain packages," and that the packages contained the circular or pamphlet later described therein; that one of the alleged misrepresentations appeared "on the label of the carton aforesaid," and that the other was "included in the circular or pamphlet aforesaid." It is matter of common knowledge that proprietary medicines in bottles are usually sold to the consumer in cartons, and that the latter usually contain circulars or other advertising matter. The court was not impressed with the suggestion that the circular was charged to have been inside "the article of drugs."

The defendant's compound was not only represented generally to be a valuable remedy for the treatment of all diseases "resulting from diseases of the brain, spinal cord and medulla oblongata, and the nerves given off from each," "a remarkable discovery for the treatment of all nervous diseases," but also a "remarkable discovery for heart troubles," as well as a "most valuable remedy for nervous prostration, mania, melancholia and neurasthenia." There was substantial testimony from competent medical witnesses that there is no remedy applicable to all the diseases mentioned; that medical science and medical experience furnish no support for the broad claims made for the defendant's remedy; that "there is no one medicine that will prove a valuable remedy for all" the diseases enumerated. There was further substantial testimony from competent witnesses that bromids, which constitute a prominent ingredient in the defendant's remedy, are sedative in their nature and, in ordinary doses, not stimulating; that while thus helpful in quieting an exalted or excited state of the nerves, as in many cases, including some cases of mania, they are not only not helpful, but are positively injurious, in depressed conditions, as in melancholia; that there is no one remedy for all spinal diseases, or for all cases of neurasthenia, or heart trouble, or for all cases of melancholia or of mania; that some diseases of the heart require sedatives, others stimulants, etc.; that the defendant's compound was dangerous to intrust to the hands of a layman. The defendant's proposition that the presence of ammonium carbonate neutralized the effect of the bromids as depressants was denied by medical witnesses for the government. True, it appeared that bromids are beneficial, at least as a palliative in quieting the nerves and inducing sleep, in ordinary cases of nervous excitability, and there was testimony on the part of the defense that several persons had received benefit, indeed, many of them claimed to have been cured, by the use of the defendant's remedy; but such testimony, at the most, bore only on the question of fact whether the alleged representations were, as made, false and fraudulent. There was still room for a conclusion that substantial mischief resided in the claim of a universally efficacious remedy for the numerous and widely prevalent maladies in question; for the term "remedy" must at least imply a curative tendency, although not, of course, guaranteeing a cure.

SOUTHERN MEDICAL ASSOCIATION

Eleventh Annual Meeting, held at Memphis, Tenn., Nov. 12-15, 1917

(Concluded from page 2144)

The Normal College as a Factor in the Dissemination of Public Health Knowledge in the South

Dr. U. F. Jones, Hattiesburg, Miss.: The normal schools are among the few largest factors in the educational scheme of this country. The normal school is not doing justice in training its teachers in health work unless it has a clinic for the diagnosis of such defects as they will constantly find in their own schoolrooms.

Oral Sepsis and the Anemias

Dr. M. L. Graves, Galveston, Texas: Anemia constitutes but one of the numerous clinical manifestations of sepsis or infection, whether it originates in the mouth or elsewhere. It is a fairly constant symptom in all the grave infections, and to a more moderate extent in the less severe ones. Sufficient is known at present to entitle us to more than a suspicion that William Hunter was correct in believing that pernicious or infective anemia should be laid at the door of mouth infection. In one case, infected teeth were removed; the patient made such rapid and marked improvement that he has resumed a laborious occupation, with the appearance of health and a blood exhibit approximating the normal. Cases of secondary anemia, associated with arthritic disease, have responded but poorly to blood tonics, such as iron. One case, in a recent experience, responded rapidly to an autogenous vaccine made from the removed tonsils containing abscesses, and the symptoms have improved in a notable way, while resistant to all other treatments, including antistreptococcic serums and stock vaccines. These experiences have led me to the belief that mouth infections are frequently the cause of acute and chronic illnesses, with or without anemia, and to the insistence that every focus of infection be removed in the effort to restore health.

Oral Sepsis and Arthritis

Dr. J. Heyward Gibbes, Columbia, S. C.: A proper investigation of the gingivae, teeth and alveolar processes must include roentgenographic studies. The important relationship of chronic pyogenic infections to a large group of the arthropathies has been conclusively demonstrated, and the first step in the management of these cases should consist in a systematic search for foci of infection. No one portal of entry for infecting micro-organisms should be allowed to obscure the importance of investigating all possible sources of infection.

Oral Sepsis and the Cardiovascular System

Dr. Alexander G. Brown, Richmond, Va.: Focal infection of the mouth, chronic alveolar abscess, chronic pericementitis, acute and chronic infection of tonsils and other oral, nasal and other cavities adjacent, produce serious, grievous and dangerous diseases of the heart, endocarditis, myocarditis, pericarditis and pancarditis.

Relation of Oral Sepsis to the Nervous System

Dr. E. Bates Block, Atlanta, Ga.: I have under my care several epilepsy patients in whom pyorrhea alveolaris or apical abscesses existed, and no other cause for epilepsy could be found after carrying out the usual methods of investigation. In view of the absence of other discoverable causes and the results obtained, I was inclined to think these cases due to this focal infection.

Relation of Chronic Infection to Thyroid Deficiency

Dr. Harvey G. Beck, Baltimore: Glandular insufficiency is of common occurrence, and is frequently overlooked. Chronic infections are almost invariably associated with glandular syndromes. These infections are usually focal in character, and seem to occur with the same relative frequency in insufficiency of the thyroid, pituitary, gonads and suprarenal. Rheumatism shows a special tendency to involvement of the thyroid. In seventy-eight of the 100 cases in my series at the time of examination, the patients suffered with chronic infections, mostly focal in character; ninety-four either showed evidence or gave a history of infection antedating the onset of symptoms. In several instances, well marked symptoms of thyroid deficiency developed after protracted acute fevers. Symptoms appeared in two cases following typhoid; one, malaria; one, puerperal infection, and one, repeated attacks of rheumatic fever. Oral sepsis and inflammatory diseases of the gallbladder and appendix play an important part in the relation of chronic focal disease and hypothyroidism, comprising 63 per cent. of the 255 infections present in the series. The remaining 37 per cent. form a miscellaneous group, and include among others pelvic infection, pyelitis, arthritis, amebic dysentery, anal fistula, syphilis and tuberculosis. Oral sepsis embracing tonsillitis, root abscesses, pyorrhea, sinusitis, etc., represents 36 per cent. of the total infections, and occurred in fifty-six of the cases. Chronic appendicitis was observed in thirty-two cases, and cholecystitis and cholelithiasis in twenty-four. In several instances, symptoms of both appendicitis and cholecystitis existed in the same individual.

The Wild Rats of the Southern States as Carriers of Spirochaeta Icterohemorrhagiae

Drs. James W. Jobling and A. A. Eggstein, Nashville, Tenn.: Published in The Journal, Nov. 24, 1917, p. 1787.

Classification and Treatment of the Acute Diarrheal Diseases in Infancy

Dr. John L. Morse, Boston: Diarrhea from an excess of fat in an artificial food is not at all uncommon. When the disturbance is a mild one, the stools are not much changed in color, but contain many small, soft curds and some mucus, and are somewhat more acid in odor and reaction than usual. Sometimes they are gray and shiny, and in other instances, when there is an excess of neutral fat, they are creamy in consistency and color. Sometimes they look like curdled milk. In other instances they are bright yellow and have an oily appearance. They are seldom green, unless there is also a disturbance in the digestion of sugar. In the worst cases, they are watery, strongly acid, and cause marked irritation of the buttocks. When this happens, the fat is in combination with the alkaline salts, especially sodium. As the result, there is a considerable loss of alkaline salts in the stools. A relative acidosis is thus produced, with an excess of ammonia in the urine. The symptoms of acid intoxication may then develop. A high fever is not uncommon in these severe cases. The prognosis depends on the severity of the symptoms, but is in general good, unless there is a marked acid intoxication. The treatment consists in the complete elimination of fat from the food. In most instances it is advisable to give a cathartic in the beginning, and to starve for from twelve to twenty-four hours. In the cases with acid intoxication, sodium bicarbonate should be given in some way and a food containing considerable amounts of sugar, preferably in the form of glucose or maltose. In the less severe cases, protein is usually well tolerated; and the caloric value of the food, which is much reduced by the withdrawal of the fat, can be made up by increasing the amount of carbohydrates. Fat can usually be cautiously added again in a few days. How rapidly it can be added can be determined only by observation of the symptoms, and examination of the stools.

Diarrhea is more often due to an excessive protein in human milk than to an excess of either fat or lactose. The protein is most likely to be excessive in the early days of lactation, and at the time of menstruation. An excess of protein may also be due to excitement, anxiety and nervousness, or to fatigue or lack of exercise. The diarrhea is usually not serious. The baby is ordinarily not very sick, and the temperature is but little, if at all, elevated. The stools are loose or watery, and often contain fat curds as the result of the increased peristalsis and the consequent interference with absorption. The stools are usually brownish yellow, but may be green. They often contain mucus. The odor is not characteristic; the reaction is alkaline or feebly acid. They are not irritating to the skin.

The most important element in the treatment of infectious diarrhea is the diet. The character of the diet depends on the variety of the micro-organism that is causing the disease. These micro-organisms can be divided, as far as the determination of the diet to be used is concerned, into two groups: (1) the various forms of the dysentery bacillus and the other organisms, except the gas bacillus, which cause the disease, and (2) the gas bacillus and allied organisms. The other organisms, although of many different varieties, are grouped with the dysentery bacilli, because as regards their growth and the production of toxic substances from protein and carbohydrate mediums, they behave in the same way.

Malaria in Infants

Dr. Morgan Smith, Little Rock, Ark.: Malarial infection is less frequent in the infant than in the child or adult, because of the vigilance on the part of the mother to protect her baby from the bites of all insects. The treatment of malaria in the infant does not differ from that employed in the child or the adult.

December, XIV, No. 6

1 *Diagnosis of Age of Fetus by Roentgenograms. J. H. Hess, Chicago.—p. 397.
2 *Internal Hydrocephalus. W. E. Dandy and K. D. Blackfan, Baltimore.—p. 424.
3 *Survey of Juvenile Delinquents. H. K. Faber and A. J. Ritter, San Francisco.—p. 444.
4 *Cause of Sudden Death in Status Lymphaticus. D. Symmers, New York.—p. 463.
5 Treatment of Eight Cases of Secondary Anemia in Infants by Blood Transfusion. C. G. Kerley, New York.—p. 470.

1. **Roentgenograms and Age of Fetus.**—Hess is convinced that the roentgenographic method of determining the age of the fetus is more reliable than determination of age based on length and other measurements, since osseous development is more regular and offers many more factors for consideration. In the early months more accurate determination is possible than in the later months.

2. **Internal Hydrocephalus.**—Twenty-six cases of internal hydrocephalus were studied by Dandy and Blackfan, fifteen of the obstructive and eleven of the communicating variety, by means of intraventricular and intraspinal injections of phenolsulphonephthalein.

Postmortem examinations demonstrated an obstruction in every case in which an obstruction had been shown clinically by this test. The obstruction may be a congenital malformation or inflammatory process or tumor, and occur at any part of the ventricular system, but usually at the aqueduct of Sylvius or the foramina of Luschka and Magendie. Hydrocephalus results because the fluid is mechanically prevented from passing from the ventricles, where the fluid forms, to the subarachnoid space, where it is normally absorbed, and where only it can be absorbed. Obstructive and communicating hydrocephalus are essentially the same, and in reality all are due to obstruction. In the obstructive variety the obstruction is in the ventricular system; in the communicating variety the obstruction is in the subarachnoid space. Obstructive hydrocephalus may, by operation or spontaneously, change to communicating hydrocephalus, or the reverse may occur spontaneously. Careful studies with the phenolsulphonephthalein test will indicate these possibilities. The authors are convinced that the surgical treatment of internal hydrocephalus has now a definite anatomic basis and hopeful prospects.

3. **Juvenile Delinquents.**—Faber and Ritter's survey is of 110 juvenile offenders. The physical findings are, on the whole, those of neglected hygiene, secondary in most cases to poverty. The mental findings show that of the boys studied 43.6 per cent. were normal, 25.5 per cent. dull normal, 17 per cent. borderline, 9.6 per cent. morons, and 4.3 per cent. imbeciles. The authors believe that for the normal boys improved environment, improved personal hygiene, and better general education would have made useful citizenship possible. The first indication is obviously to separate the normals and dull normals from the rest, to keep the borderline cases under observation, with careful and systematic attempts to education in order to determine and develop latent ability; and finally to segregate promptly those who are beyond question feebleminded. The authors prefer the Yerkes-Bridges-Point Scale to the Binet-Simon tests. They claim greater accuracy for the former.

4. **Sudden Death in Status Lymphaticus.**—Symmers says that among the first 4,000 necropsies at Bellevue Hospital, status lymphaticus was encountered in 249 subjects, or in 6.2 per cent.; 118 examples of status lymphaticus were encountered; 89 cases belonged to the recessive type; 42 were borderline cases. Of the 118 cases of straightforward status lymphaticus, the thymus was enlarged in every case. The faucial tonsils were enlarged 61 times; the lingual tonsils 58 times; the pharyngeal lymphoid follicles 45 times; Peyer's patches and the solitary follicles 105 times; axillary nodes 11 times;

inguinal nodes 12 times, and the cervical nodes 15 times. The spleen was small or normal in size in 68 cases; the malpighian follicles were hyperplastic 101 times. Of 89 cases of recessive status lymphaticus the thymus was weighable 19 times, and the average was 18 gm. In the remaining 70 cases the thymus was completely replaced by fat. The faucial tonsils were hyperplastic 25 times; the lingual tonsils 32 times, and the pharyngeal tonsils 19 times. Peyer's patches were atrophied 61 times; solitary follicles 37 times. The splenic follicles were enlarged 37 times and atrophied 39 times. The spleen was normal or small in size in 52 cases (71 per cent.).

According to Symmers, sudden death in status lymphaticus may be occasioned, first, by an anaphylactic reaction due to sensitization of the body by a specific nucleoprotein formed in the lymph nodes as the result of necrosis of numbers of germinal follicles. Before the so-called anaphylactic incubation period has expired the tissues are again subjected to the action of the same protein formed in the same type of tissue in response to an apparently trivial injury, and, in this way, the anaphylactic reaction is completed. Second, spontaneous rupture of an hypoplastic cerebral vessel, or rupture following apparently trivial injury, the deficiency in the vessel wall being most noticeable in the muscular coat.

7 Orthcarteriotony (New Form of Pharmacodynamic Energy). C. J. Enebuske, Sater, Sweden.—p. 799.
8 *Tendon Suture. T. W. Harmer, Boston.—p. 808.
9 *Testing and Recording Vasomotor Reflexes of Skin. E. A. Tracy, Boston.—p. 810.
10 Speech Correction—New Medical Study and Educational Movement. W. B. Swift, Boston.—p. 811.

6. **Radioactive Substances in Treatment of Malignant Disease.**—Over 500 new cases of malignant disease a year are seen at the Huntington Hospital, almost all of which receive treatment with radioactive substances. In some cases, very satisfactory results have been obtained, giving what may be called apparent cures. In others, marked alleviation has been observed, with prolongation of life and increased comfort; and in other cases still, no benefit, and possibly added discomfort, may have been produced. Duane's paper contains a detailed statement of methods employed in preparing the radioactive substances, of the methods of measuring the dosage, and of the general principles on which the character of the treatment is determined; a description of the scientific principles employed in the preparation of the applicators and of the instruments for measuring their radioactivity, and a brief statement of the kinds of cases in which the various methods are used and the dosages actually employed.

8. **Tendon Suture.**—Harmer uses silk and overcasts the lateral margins of both ends of a divided tendon. The overcasting starts about the width of the tendon or a little more back from the point of division, and comprises several whippings about the side of the tendon down to the line of division, each loop including somewhat less than one-quarter of the circumference of the tendon. When a tendon is ready to be brought together, each end then carries two stitches and each stitch two ends. The two parts of the tendon are now brought together and the two suture-ends nearest the line of division on one side are tied. The two pairs of stitch-ends on the other side are then similarly tied. The long ends so tied alongside the tendon seem to serve as lateral splints.

9. **Method of Testing Vasomotor Reflexes of Skin.**—In a normal person, when the skin is lightly stroked (with a pressure of about 2 ounces) there appears on the stroked surface a brief deepening of the skin tint lasting up to eight or twelve seconds, and then a white streak appears that lasts for a couple of minutes. The blood vessels in the stroked area dilate and then contract. In each case tested four tests are made: 1. The skin of the left side of the face is stroked, and the length of time the reflex vasodilatation lasts and the time it takes the reflex vasoconstriction to appear is noted; this is done with the aid of a stop-watch. The length of time the vasoconstriction lasts is also noted. 2. The same is done for the right side of the face. 3. The left forearm, on the palmar surface, an inch or so from the wrist, is similarly stroked. The time the vasoconstriction appears and its duration are noted. 4. The same is done for the right forearm. A study of the reactions in normal and diseased individuals has led to important findings of use in diagnosis.

23 *Dilatation of Lateral Ventricles as Common Brain Lesion in Epilepsy. D. A. Thom, Palmer, Mass.—p. 355.

20. **Chronic Progressive Lenticular Degeneration.**—The cases reported by Thomas comprise three children in one family, similarly affected, thus showing the familial character of Wilson's disease, with no discoverable heredity. These cases differ in several essential points from those reported by Wilson, first in the character of the tremor, the absence of fixed spastic smile, the dysphagia, and especially in the evidence of the affection of the pyramidal tracts. There was also no evidence of any affection of the liver so far as could be determined. In some respects these cases much more closely resemble multiple sclerosis, yet there are various and important reasons for rejecting this view. First, the distinctly familial character of these cases with three children out of six in one family affected, and a fourth probably beginning to show the characteristic signs, which are so similar that even the parents now have grown to expect the appearance of the symptoms as the children approach the age of 8 years. Then the absence of nystagmus and changes in the eyegrounds, and the steady progressiveness of the disease, the absence of remissions in the symptoms, and most important of all, the mental deterioration must be considered. These cases resemble those described under the title of pseudosclerosis. They showed no pigmentation of the skin or cornea, no epileptiform attacks, no enlargement or diminution in size of the liver, and were distinctly familial in character.

22. **Brain Tumor Clinically Considered to Be Paresis.**—Lowrey presents a study of a case of glioma involving the third and posterior portion of the lateral ventricles and the corpus callosum. The case was diagnosed as paresis but no evidence of paresis was found in the microscopic study of the cortex.

23. **Dilatation of Lateral Ventricles as Brain Lesion in Epilepsy.**—Since January, 1913, Thom has collected the brains of 75 epileptic subjects, the results of 82 consecutive postmortem examinations; 57 of this group presented gross brain lesions; 31 of these 57 cases presented cortical lesions as well as dilated ventricles; 16 showed lesions of the cortex alone, while the remaining 14, with a normal looking cortex, had dilated lateral ventricles. Of the entire 43 cases reveal-

ing cortical lesions, the hind portion of the brain was by far the most frequently affected, especially the occipital lobes. The convolutional shrinkage in this region was often marked, and the appearance was that of an acquired condition rather than one of congenital origin. Next in order of frequency was the general cerebral gliosis, where the entire cerebrum appeared to be involved. Softenings were noted only six times, once being general, the other five times being focalized. There were 29 cases of well defined sclerosis of the basilar and cerebral vessels. Gliosis and atrophy of one hemisphere alone was noted in 8 cases, equally divided between the two hemispheres. In the dilated ventricle group were 41 cases; 27 of the brains in this group also had abnormalities of the cortex. The remaining 14 cases with dilated ventricles, where the cortex of the brain was not grossly abnormal but where the ventricular dilatation was of such a degree as to leave no doubt of its abnormality, raises the question in Thom's mind as to whether lesions affecting primarily the white matter may not be a factor in the production of epilepsy.

8 Early Diagnosis of Venereal Disease and Laboratory Aids to Successful Treatment. J. McCullagh.—p. 212.

6. **Pathologic Report of Rotunda Hospital.**—Rowlette's report covers a period of two years, from Nov. 1, 1914, to Oct. 31, 1916. Curettings and other fragments removed for purposes of diagnosis were examined on 222 occasions. One case of tuberculous endometritis was encountered, associated with tuberculosis of the tubes. The great majority of curettings (114 out of 138) showed definite glandular changes, varying from moderate increase in number to considerable hypertrophy, with invagination of epithelium, and in eighteen cases, formation of cysts. Twenty-two cases of malignant disease of the uterus were dealt with by operation. Of these cases, fifteen were epithelioma of the cervix, and one adenocarcinoma of the cervix, three adenocarcinoma of the body, two sarcoma of the body, and one chorionepithelioma. Sixty-three cases of myoma were examined. In twenty-six secondary changes other than fibrosis, which is almost always present, had occurred. Of forty-one cases of salpingitis examined, only seven were tuberculous. Of forty-eight cysts of the ovary, four were dermoids, eight syphilitic cysts, twenty-four smooth walled cystadenoma, and thirteen papillary cysts, eight of which gave histologic evidence of malignancy. Three solid tumors of the ovary came under examination, of which number two were carcinomas, and the other was a fibroma.

14. **Tartar Emetic in Treatment of Malaria.**—Eight cases were treated intravenously with tartar emetic. They include infections both with benign and malignant tertian parasites. The tartar emetic was used in a 2 per cent. solution, to which 0.5 per cent. phenol was added to preserve its sterility. Of these eight cases there were two mixed infections, one subtertian malaria and five benign tertian malaria, three of which showed gametocytes. Of the two mixed infections, the crescents disappeared in both cases, the benign tertian parasites persisting in one and disappearing in the other. In the subtertian crescent infections the crescents disappeared after three injections of tartar emetic. In spite of the disappearance of the crescents the patient had three typical clinical attacks of malaria, though the parasites could not be demonstrated again in the peripheral blood stream. Of the five benign tertian infections, in none did the parasites disappear from the blood stream till large doses of quinin had been administered. In the three patients in which gametocytes were seen, in two the gametocytes were not found subsequent to the tartar emetic treatment; in the other patient the gametocytes persisted. Neither in the subtertian cases, nor in the benign tertian cases, was any marked clinical improvement noted, and in the benign tertian cases the tartar emetic did not appear to exert any effect whatever on the parasites.

15. **Mortality from Postcholeraic Uremia.**—Rogers records a 70 per cent. reduction in the mortality through the intravenous injections of sodium bicarbonate. Two solutions are now used. The first is the hypertonic saline, which Rogers has given with much success in well over 1,000 cases during the last ten years. It consists of 120 grains of sodium chlorid with 4 grains of calcium chlorid to a pint of sterile water. For several years now Rogers has omitted the potassium chlorid of Ringer's fluid, as some physiologists regard this as an unnecessary and possibly depressant addition, and the increasingly favorable results obtained in recent years show that it is certainly not required. The second, or alkaline solution, contains 60 grains of sodium chlorid and 160 grains (2 per cent.) of sodium bicarbonate, and is thus also a hypertonic fluid. To avoid decomposition of the bicarbonate on boiling, the chlorid solution is sterilized before the bicarbonate is added, and the latter sterilized in packets in an autoclave and subsequently added.

In patients admitted early without prolonged suppression of urine the hypertonic sodium chlorid solution only is used at the first transfusion, the quantity being regulated by the specific gravity of the blood. If the case is sufficiently severe to require further intravenous injections, at each subsequent transfusion 1 pint of the alkaline solution is first given and followed by the hypertonic chlorid solution in the quantity indicated by the specific gravity of the blood. In patients admitted late with suppression of urine for twelve hours or more the alkaline solution is given at the first injection as well. Moreover, it is used in all cholera patients with deficient urinary secretion without much concentration of the blood as shown by the specific gravity, in which the normal saline was formerly advised by Rogers. As long as the specific gravity of the blood is not much below the normal, such as not less than 1,050, a pint of the alkaline solution can always be safely given intravenously for deficient secretion of urine. In addition, this solution is now used in the place of normal saline by the bowel when formerly advised.

Archives des Maladies de l'Appareil Digestif, etc., Paris

September, IX, No. 6, pp. 297-360

20 Mathieu and the Pathology of the Digestive Apparatus. J. C. Roux.—p. 297.
21 *Hypertrophic Stenosis of the Pylorus in Adult. L. Urrutia. p. 333.
22 *Dyspepsia After Loss of Teeth. A. Mollière.—p. 337.
23 *Stomach Disturbances in the Gassed. E. Agasse-Lafont and J. C. Roux.—p. 341.

21. **Stenosis of the Hypertrophied Pylorus in Adult.**—The woman of 43 had eight children and had always been well until the last year. The assumption of cancer at the pylorus was sustained by occult blood in the stools. Several ascarides were found at the resection operation but nothing to suggest malignant disease. Urrutia believes that the helminthiasis must have been responsible for the occult blood.

22. **Dyspepsia after Loss of Teeth.**—Mollière provides at the regiment infirmary a special diet for men without teeth. It is planned so it will not hurt the gums and yet will keep up the habit of mastication. The vegetables, etc., are cooked extra thoroughly but are not mashed. The meat is given in the form of meat juice or finely chopped meat. As men with defective or no teeth do not masticate normally, there is not the normal stimulus for secretion of saliva. To remedy this he adds condiments in moderate amounts to the food: pepper, salt, thyme, laurel and onions.

23. **Injury of the Stomach in the Gassed.**—Lafont and Roux give the details of five cases in which gassed soldiers suffered from the stomach the next day, vomiting after each meal for several days and then developing all the symptoms of gastric erosion or ulcer. One man vomited blood on two occasions. Another had melena and the erosion seemed to be in the duodenum. Gastro-enterostomy was done in this case and all symptoms subsided. No operation was attempted in the other cases, and only partial improvement has been noted to date under strict courses of treatment as for gastric ulcer. The gas was of the "weeping gas" type.

Archives de Médecine et de Pharmacie Militaires

March, LXVII, No. 3, pp. 309-452

24 *Flying Base Hospital. (Nouveau type de formation chirurgicale mobile.) L. Plisson.—p. 309.
25 Indications for Different Types of Artificial Legs. M. Séron. —p. 353.
26 *Identification of the Dead in War. L. Bosredon.—p. 369.

24. **Flying Base Hospital.**—Plisson's system of interchangeable automobile units to constitute a base hospital that can be enlarged or reduced at need and moved rapidly by its own power to points where it is needed at different times, was described recently in THE JOURNAL, page 1914. The complete details of equipment, etc., are described here, with illustrations.

26. **Identification Tags.**—Bosredon comments on the large number of "missing" in each of the belligerent armies. This testifies that the present methods of identification of the dead have not proved efficient. He describes the various methods that have been adopted and some that have been discarded. In Italy, since 1915, the soldiers have been wearing a hinged metal tag that contains a folded paper with full identification details. The two small sheets of metal thus form a case suspended by holes at the outer end. The Austrians use a similar double metal tag. Russian soldiers carry no provision for identification. The Belgian army insists on conveying all cadavers to the rear, each division having a morgue with special vehicle. This permits identification at leisure. Bosredon has devised a wrist tag and already thousands have been distributed to the soldiers. It consists of a small metal plate with name and other details stamped on it in duplicate, above and below, with a line of perforations between. This permits the lower half to be torn off for identification purposes, while leaving the other half permanently on the cadaver. It is fastened to the wrist with a light metal chain and rivet. The details regarded as indispensable are the name and the year of enrolment on one side of the tag; the number of the recruiting office and the number given the recruit are on the back of the tag. The tags already in use can be utilized by adding the wrist chain.

27 Malaria in French Forces in Macedonia. P. Carnot.—p. 353; E. Marchoux.—p. 360.
28 Technic for Examination of Blood in Malaria.—L. Tribondeau. —p. 364.
29 *Initial Symptoms of Malaria. Mauban.—p. 368.
30 Technic for Giving Quinin in Malaria. C. Garin.—p. 373.
31 Arsenic in Malaria. P. Carnot.—p. 379.

November 10, No. 45, pp. 389-404

32 Cardiovascular Disturbances in the Gassed. J. Parisot and L. Tixier.—p. 389.
33 *Epidemic of Scurvy. P. Harvier.—p. 394.
34 Thorium Sulphate in Intestinal Infections. Fenestre and Gérard. —p. 398.
35 *Verrucous Lesions Simulating Verrucous Tuberculosis. H. Gougerot.—p. 399.

29. **Initial Symptoms of Malaria.**—This entire issue of the *Paris Médical* is devoted to diseases of exotic origin, malaria in particular. Mauban analyzes the findings in seventy-two cases of primary malaria in August in Macedonia, commenting especially on the sudden severe onset. The weakness was so extreme in all but one case that the men had to lie down where they were, too weak even to fire their gun to call attention to their sudden sickness. Bronchitis with spasmodic coughing was almost the rule, notwithstanding the warm weather, as an early manifestation of the malaria. In 75 per cent. of his cases the eyes were bloodshot and tender, in addition to the ordinary symptoms of malarial infection.

33. **Epidemic of Scurvy.**—Harvier describes the scurvy he has encountered in soldiers who have been unable to get any fresh vegetables for periods of from four to six months. He sought out the camp from which these men came, and found 184 excused from duty on account of "abscess," "lymphangitis," "rheumatism" or other diagnosis, but at a glance he recognized scurvy in all. Ranging the other men in two rows, he passed along inspecting the gums of each, and in almost 20 per cent. he found the gingivitis of scurvy. Fully 95 per cent. of the body of 817 men had had scurvy.

35. **Verrucous Nontuberculous Skin Lesions.**—The importance of the verrucous epidermitis which Gougerot describes lies in its deceptive resemblance to verrucous tuberculous affections. Only the absence of antecedents, the multiple onset and rapid development distinguish it at first, but it usually heals at once under treatment with dressings impregnated with a 1:30 solution of resorcin, followed by paste of yellow oxid of mercury.

36 *Stiff Ankle. Ducroquet.—p. 597.
37 Treatment of Imported Malaria. A. Manaud.—p. 599.

October 22, No. 59, pp. 605-616

38 *Tachyphylaxis. H. Busquet.—p. 605.
39 Quadrant Hemianopsia and the Cortical Center for Vision. A. Monbrun.—p. 607.
40 Plantar Paralysis. L. Moreau.—p. 609.
41 Technic for Laminectomy. E. Girou.—p. 610.
42 *Urine Test for Typhoid. H. Diacono.—p. 611.

36. **Stiff Ankle.**—Ducroquet gives a profusely illustrated review of the disturbances in the gait with ankylosed ankle.

38. **Tachyphylaxis.**—This term was coined to express the rapid immunization conferred by injection of a small preliminary dose. The immunization is complete in a few minutes, so that injection then of a large amount does not have the action that it would have had if the preliminary small dose had not been injected. Busquet reports experimental research in this line. Attempting to apply the conclusions to man, he was unable to detect any immunizing action from a preliminary small dose of colloidal metals. In animals, the tachyphylaxis was marked with certain drugs used by intravenous injection in the clinic. It was also evident in man with sodium nucleinate, chaulmoogra oil and the arsenobenzenes. A small preparatory dose of either of these enabled a large dose, given a few minutes later, to be tolerated without the reaction inevitable otherwise. The data already acquired justify the application of this principle of an immunizing preliminary dose in transfusion of defibrinated blood in case of hemorrhage; also with intravenous injection of organ extracts in cases of glandular insufficiency.

42. **Diagnosis of Typhoid from the Urine.**—Diacono's test is based on determination of the precipito-agglutinable substances in the urine under the influence of typhoid antiserum. He uses a set of test tubes with 20 c.c. urine, one containing normal urine. To each tube is added from 0.1 to 0.5 c.c. or 1 c.c. of typhoid antiserum. After incubation at 37 C. for three or four hours, a flaky sediment is apparent in the positive cases while the control tube keeps clear. The urine must not be filtered. A trace of salt added to the urine hastens the precipitation.

Progrès Médical, Paris

November 3, XXXII, No. 44, pp. 369-376

43 *Protection for Soldier's Heart. Filderman and Bonnette.—p. 369.
44 Rapidly Fatal Addison's Disease in Course of Tuberculous Pleurisy. J. Tapie.—p. 371.

43. **Protecting Devices for the Soldier.**—Fildermann and Bonnette remark that the weight and clumsiness of a really protecting cuirass forbid its use to date, but that there is every reason for some light device to protect the heart. This is a peculiarly vulnerable region as there is no natural protection here, while the slightest wound of the heart may prove fatal. They suggest, until something better can be devised, to have a thin sheet of metal, about 2 mm. thick, sewed between the coat and its lining over the heart region. It could reach to the collar of the coat and lie just outside of the buttonholes. Suitable dimensions would be 15 cm. in height by 13 at the base, the part near the shoulder slanting from the neck outward, leaving the outer straight edge at the base only 6 cm. A sheet of metal of the kind need not weigh more than 250 gm.

Correspondenz-Blatt für Schweizer Aerzte, Basel

November 10, XLVII, No. 45, pp. 1505-1536

45 *The Developmental Cycle of the Bothriocephalus Latus. C. Janicki and F. Rosen.—p. 1505.
46 Avirulent Diphtheria-Like Bacilli. J. L. Burckhardt.—p. 1517.
47 *Roentgen Treatment of Disease of the Nails. L. Merian.—p. 1521.

45. **Development Cycle of Bothriocephalus.**—The research here reported has supplied the missing link in the development of the *Bothriocephalus latus L.* The larvae are eaten by the *Cyclops strenuus* and *Diaptomus gracilis.* These form the intermediate link, and as they are eaten by fishes, the parasite finds its way to man, dog and cat, and the cycle starts anew. Each of the five phases of the cycle may take up to three or four weeks. The work was done at the laboratories of the Universities of Lausanne and Neuchâtel.

47. **Disease of the Nails.**—Merian gives illustrations before and after roentgen treatment of slow pathologic processes in the matrix of the nails—onychia, usually traceable to some solution of continuity in the skin nearby. The results were excellent, the nail returning to normal without the disfigurement usual after such processes. One to three exposures answered the purpose. A single exposure proved effectual for one tuberculous process of the kind which had persisted for two years rebellious to various measures, including curetting and heliotherapy. The aspect of the thumb now seems quite normal. With psoriasis and eczema, he exposes the skin around to the usual eczema dose, but gives the nail matrix the deep dose, from 3 to 8 H, in one sitting.

Riforma Medica, Naples

October 13, XXXIII, No. 41, pp. 973-992

48 *To Free Convalescents of Typhoid Bacteria. L. Preti.—p. 973.
49 Dissociated Cortical Paralysis After War Wound and Localizations of Motor and Sensory Functioning. E. Salkind.—p. 974.

48. **Treatment of Bacilli Carriers.**—Preti noticed that the serum of patients convalescing from typhoid never contained agglutinins in any proportion when typhoid bacilli could still be found in their stools. This suggested that by artificially increasing the agglutinins it might be possible to free the men from the bacilli. He consequently gave a small injection of antityphoid vaccine. There was always a pronounced general reaction, and the typhoid bacilli disappeared from the stools thereafter. Although his experience is limited, the unfailing success justifies trials of this means of curing carriers of typhoid and possibly of other germs.

Rivista Critica di Clinica Medica, Florence

October 20, XVIII, No. 42, pp. 409-420

50 *Nervous and Functional Disordered Action of the Heart in Soldiers. N. Pende.—p. 409. Commenced in No. 38, p. 365.
51 Big Abdomen in Soldiers. S. Pisani.—p. 412. Continuation.

50. **Disordered Heart Action in Soldiers.**—Pende has found that all the purely nervous and functional heart disturbances which he has encountered in soldiers can be roughly classified in four groups: those with indications of excessive thyroid functioning; those with vagotonia; those whose hearts are not well developed and strong; those with symptoms deceptively simulating myocarditis. When the case can be ranged in one of these classes, the indications for treatment are apparent at once. For the thyroid group, bland local radiotherapy of the thyroid and galvanization of the thyroid and cervical sympathetics might be tried, supplemented by pluriglandular organotherapy. Or pituitary treatment might counteract the thyroid, or minute regulating doses of thyroidin. He warns, however, that even at the best—when myasthenia cordis can be excluded—the heart in these cases may become suddenly strikingly disordered, with crises of depression which might prove dangerous in active military service. There may be some infectious factor along with the excessive thyroid functioning—Simmonds, Faha and others have recently demonstrated degenerative lesions in the myocardium of persons who had had exophthalmic goiter during life.

The men with myasthenia cordis should be given only light duty not calling for muscular effort. The vagotonic type of disordered heart action gives the best prognosis; treatment should consist in moral suasion, diversion, graduated exercises, good food and fresh air and mild hydrotherapy. In his fourth group, the adynamic, pseudomyocarditis cases, hospital treatment and psychotherapy do not have the slightest effect. The men can be given specialist neurologic treatment for a time, but the best plan is to send them home at once on a long furlough.

Hospitalstidende, Copenhagen

October 17, LX, No. 42, pp. 1021-1048

52 *Trichinosis in Denmark. J. Fibiger.—p. 1021.

52. **Trichinosis in Denmark.**—Fibiger reiterates that the meat from even one hog with trichinae is liable to start an extensive epidemic, as occurred at Hedersleben where 337 persons were affected and 101 died. The measures for control of trichinosis in Denmark have shown their efficiency in late years not only in the great reduction of cases in man but also in the reduced infestation of dogs and cats with trichinae, which they acquire from swine and rats. Rats become infested from the hog most frequently of all. In 1904-1905 more than 3 per cent. of the necropsies at Copenhagen's public hospitals showed the presence of trichinae; in 1910 the proportion was only 0.6 per cent. The meat control inspection revealed from six to nine hogs with trichinae in 1911-1913; thirteen in 1914 but only one in 1915. During the two latter years however, 693 sides of salted meat imported from America were found to contain the trichina.

53 *Mastoid Operation Fatalities. G. V. T. Borries.—p. 1715.
54 Length of Sanatorium Courses. O. Helms.—p. 1721.

October 25, No. 43, pp. 1741-1776

55 Treatment of Scabies. L. Nielsen.—p. 1741.

53. **Mastoid Operation Fatalities.**—Borries relates that during the last ten years 1,108 mastoid operations have been performed in Mygind's service at Copenhagen, and 10.7 per cent. of the patients died. The ages ranged from 2 months to 76 years. In only fourteen of the total 119 deaths was the operation in itself probably responsible for the fatal outcome. This mortality, corrected, amounts to only 1 per cent. of the total 1,108 operations. In fourteen other cases, serious postoperative complications developed, but the patients recovered. The danger of complications does not seem to be any greater with total than with simple mastoid operations, but if meningitis does occur it is liable to be more serious with the total operation.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER, 1917

The following journals have been abstracted in the Current Literature Department of THE JOURNAL during the past six months. Any of the foreign journals, except those starred, will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. Only one journal may be borrowed at a time. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Domestic journals can be obtained by sending the approximate amount direct to the respective publishers. Thus most of the journals indexed are accessible to the general practitioner, no matter where he may be located.

SUBJECT INDEX

This is an index to all the reading matter in The Journal. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "T," Therapeutics; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an "Original Article" in The Journal.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D" and "S." Matter pertaining to the Association is indexed under "American Medical Association."

The name of the author follows the subject entry in brackets. The figures in parentheses refer to the paragraph in the Current Medical Literature Department, the number following to the page in The Journal.

For author index see page 2245.

A

ABDERHALDEN REACTION: See under names of various diseases
ABDOMEN, drainage of, posture in cases of, [Hill] (25) 1736
  perforation of abdominal viscera, [Tennant] 1561—ab
  pressure, intravisceral and intra-abdominal, [Coffey] *683
  protection of chest and, of combatants, 1457, [Delorme] (37) 1568
  Ptosis of: See Splanchnoptosis
  rectangular flap incision for operations within upper abdomen, [Meyer] *1677
  rigidity of wall of, with war wounds, [Willems] (42) 2073
  sarcoma in, in young woman, polyserositis with, [Kramer] (130) 499
  wounds in war, [Eastman] 1560—ab, (23) 2069
  wounds, laparotomy for, unusual complications of, [Johnston] (7) 1642
  wounds, penetrating, treatment in hospitals at front, 660
  wounds, subnormal arterial pressure with, [Chiasserini] (65) 1916
  wounds, treatment at advanced posts, [Schwartz] (57) 156
ABDOMINOCARDIAC and oculocardiac reflexes, [Pron] (53) 1036
ABORTIFACIENT, nitrobenzol not an, [Spinner] (54) 2155
ABORTION, active versus conservative treatment of, [Engler] (44) 947
  causes of, statistical study of, [Royston] (3) 1647
  criminal, repression of, [Berthélemy] (35) 1568
  notification of miscarriages and, [Bar] (46) 1742
  presumption from commission of numerous, 938—Ml
ABSCESSES: See also Phlegmon; and under names of organs and regions
ABSCESSES, chronic, [Filardi] (82) 1387
  in myositis purulenta tropica, etiologic agent and localizing factor of, [Walker] (35) 1030
  tuberculous, present day treatment of, [Delaney] (161) 492
ABSORBABLE metal clips as substitutes for ligatures and deep sutures in wound closure, [Andrews] *278, [Kane] 663—C
ACCIDENTS, industrial, laws on war wounds and, [Imbert] (66) 2075
  prevention and welfare work in large industrial plant, 725—ab
  street, increase in, 375—ab
ACETANILID and sodium bicarbonate, 1375
ACETONEMIA, [Guidi] (75) 1917
ACHILLES TENDON, percussion of, flexion of big toe on, [Villaret & Faure-Beaulieu] (66) 1656
  sensory, sign with sciatic disease, [d'Allonnes] (81) 496
ACHYLIA gastrica, [Mortimer] 1467—ab
  gastrica, diarrheas accompanying, [Rehfuss] *1328
ACID, acetylsalicylic, 199
  acetylsalicylic acid (Aspirin), Monsanto, 1695
  acetylsalicylic acid—Milliken, 1695
  acetylsalicylic, chronic poisoning from [Stiell] (35) 1383
  acetylsalicylic, with quinin, incompatibility of, 1375
ACID, Carbolic: See Phenol
  citric and malic, in various fruits, 1132—E
  citric, in urine, [Amberg & McClure] (6) 2146, 2120—E
  glucuronic, action of inosite and similar bodies on elimination of, [Sasaki] (86) 77
  hydrochloric, effect of, on mineral excretion of dogs, [Stehle] (69) 850
  Intoxication: See Acidosis
  lactic, bacilli in leukorrhea, [Block & Llewellyn] *2025
  lactic, in stomach, errors in deductions from presence of, [Rodella] (75) 2075
  lactic, in urine, Schneyer method for determination of, [Mayer] (45) 1649
  malic, behavior of, in body, 44—E
  nucleic, chemical structure of, 1431—E
  output of bases after intake of acid, 1172—E
  oxalic, in foods, 1699—E
  picric, in urine, test for, 39—ab
  picric, urines of workers in, [West] (22) 755
  Salicylic: See also Salicylates
  uric, alleged perils of, [Berkart] (2) 1033
  uric, and maternal and fetal blood, [Slemons & Bogert] (41) 1649
  uric, endogenous, physiology of, [Høst] (86) 1573
  uric, in blood of new-born, [Sedgwick & Kingsbury] 147—ab, (3) 588
  uric, in gout, [McClure and Pratt] (39) 1737
  uric, infarcts in new-born, 1699—E
ACIDOSIS and acid excretion in pneumonia, [Palmer] (40) 1379
  and anesthesia, relation between, [Caldwell & Cleveland] (113) 241
  bicarbonate concentration of blood plasma, significance and determination as measure of, [Van Slyke & Cullen] (50) 149
  blood and urine ammonia in, [McNeil & Levy] (47) 1910
  blood lipoids and nephritis, 1976—E
  in diabetes and nephritis, [Christie] (50) 407
  newer conception of, 646—E
  postoperative, [Jeans & Johnson] (7) 311
  studies of, [Van Slyke & Cullen] (50, 51] 149
ACNE as cause for rejection, 128
  vulgaris, roentgenotherapy of, [Hazen] *977
ACRIFLAVINE, antiseptic properties of proflavine, brilliant green and, [Browning & others] (20) 673
  relative germicidal efficiency of antiseptics of chlorin group and, [Dakin & Dunham] (13) 2151
ACROMEGALY, roentgenotherapy of, [Nordentoft] (108) 1122
ADAMANTINOMA showing epithelial pearls, case of, [Graves] (8) 1029
ADAMS-STOKES' DISEASE: See Heart-Block
ADDISON'S DISEASE, actions of epinephrin on, [Burridge] (22) 72
  epinephrin in, [Nolf & Fredericq] (38) 1475
ADENECTOMY, complications and end-results of tonsillectomy and, [illegible] source of [illegible] & Cheville] (43) 2154
ADENOIDS, pituitary deficiency with, [Citelli & Caliceti] (60) 246
ADENOMYOMA of rectovaginal septum, [Cullen] (46) 1999
ADENOSARCOMA in right kidney in girl of 6, [Kirmisson & Trétiakoff] (28) 72
ADRENALIN: See Epinephrin
ADRENALS: See Suprarenals
ADVERTISEERS, weird logic of certain, 1010—E
ADVERTISING, medical, in New York Medical Journal, 1010—E
  medical, Times-Picayune accepts only that investigated and passed on by state board of health, 2133—P
  remedies for venereal diseases, law prohibiting, 1021—P
  under name other than own to practice medicine, 845—Ml
AEROPLANE, industrial poisoning in manufacture of, [Hamilton] *2037, 2041—E
AGAR-AGAR, liquid, in constipation, [Brown & Sweek] *467
AGARICIN, [McCartney] (87) 315
AIR, alveolar, changes in composition of, during inspiration and expiration, [Pearce] (9) 1735
  alveolar, in asthma, 827—E
  force, specialized medical service for, 2134
  raid and hospitals, 222
  raid, casualties of, 301
  raids on London, 1551
  tidal, effect of accumulation of carbon dioxid on H-ion concentration of arterial blood and on tidal air in decerebrate cat, [Scott] (10) 1294
ALABAMA examination, candidates' deficiences at, 665
  medical news, 130, 835
  reciprocal relations of, 685
  state board July examination, 1996
ALBUMIN, dissolved, in stomach content, differential valuq of, [Udaondo] (70) 949
ALBUMINURIA and hematuria following administration of hexamethylenamin, [Wiseman] (19) 754
  [illegible] changes following [illegible] of full [illegible] salicylate, [Hanzlik & others] (64) 69
  long-standing, causation and curability of, [Riesman] *2009
  postoperative, [Satre] (44) 244
  trench, [Teissier] (12) 594
ALBUMOSES in tissues and blood with reference to occurrence in gastro-intestinal mucosa, [Abel & others] (6) 1735
ALCOHOL, action of House of Delegates of American Medical Association on, [Hare & Green] 226—C
  as cause of insanity, decline of, [Pollock] (65) 756
  effect of, on reproductive tissues, [Arlitt & Wells] (54) 2149
  from standpoint of pharmacology and therapeutics, [Fantus] *10
  in pneumonia in early infancy and childhood, [Koplik] *1661
  medical science and, [Kane & Hawkes] 1289—C
  nerve blocking in causalgia, [Pitres & Marchand] (60) 1477
  sale of beverages containing, 302
  soap, [Nogier] (39) 946
  war revenue laws and dispensing of, by physicians, 2121
ALCOHOLISM, campaign against, [Coni] (127) 678
  repression of public drunkenness, 1722
ALCRESTA Ipecac, 1373—P
ALIMENTARY TRACT: See Gastro-intestinal Tract
ALIMENTATION, Advisory Committee on, 920
ALLERGY: See Anaphylaxis; Immunity
ALOPECIA areata and defectively developed teeth, connection between, [Sabouraud] (46) 1303
ALVARENGA prize, 1369
ALYPIN, action of, on bladder, [Waddell] (73) 1738
AMBARD'S urea constant in surgery, [Legueu & Chabanier] (51) 2074
AMBLYOPIA, optochin, [Schiøtz] (140) 500
AMBOCEPTOR, antisheep hemolytic, preservation of, in glycerol, [Clock & Beard] (51) 1380
AMBULANCE driving not "an old man's job," [Williams] 62—C
  Red Cross, enlistment in service, not to exempt from draft, 478
AMEBA, detection of, technic for, [Ravaut & Krolunitsky] (32) 595
AMEBIASIS: See Dysentery, Amebic
AMERICA, medical military utopia, 1010—E
AMERICAN Academy of Ophthalmology and Oto-Laryngology, meeting of, 1369, 1720
  ambulance corps at Neuilly, 578
  Association for Study and Prevention of Infant Mortality, meeting of, 1285, 1455
  Association of Anesthetists offers services in instruction, 133
  Association of Electrotherapeutics and Radiology, new officers of, 1549
  Association of Military Surgeons, meeting at Fort Benjamin Harrison, 1272, 1355
  Association of Obstetricians and Gynecologists, meeting of, 395
  Association of Railway Surgeons, officers of, 1455
  Automobile Club, donations from, 1633
AMERICAN MEDICAL ASSOCIATION, Chicago session, committee on arrangements, 1723
  Council on Medical Education, standards of, 546
  House of Delegates on alcohol question, [Hare & Green] 226-C
  pamphlets on medical military information for physicians, 830
  practical economy, 2116—E
  Section on Gastro-Enterology and Proctology, retrospect and prospect, [Murray],*1481
AMERICAN Museum of Safety, 4th annual congress, 925
  Orthopedic Association elects officers, 395
  Public Health Association, change of meeting place, 660
  Public Health Association, new officers of, 1550
  Public Health Association, special war meeting, 1090
  Red Cross: See Red Cross, American
  Review of Reviews and New York Medical Journal advertising, 1010—E
  Social Hygiene Association, meeting of, 1285
  spas and war, 1881
  students in Paris, home for, 1551
AMMONIA in blood and urine in acidosis, [McNeil & Levy] (47) 1910

AMNESIA, malarial, [de Brun] (45) 2154
  traumatic, [Oppenheim] (51) 320, (82) 497
AMNIOTIC fluid, tint of, as sign of fetal monstrosity, (69) 322
AMPUTATION, first devices to aid amputated, [Baudet] (32) 2152
  method of flapless amputation with subcutaneous division of bone at higher level, [Handley] (3) 1114
  reamputation, [Chapple] (2) 1114
  technic for, [Fieux] (34) 73, [Lerda] (79) 1387, (69) 2005
AMYL nitrite and atropin test in bradycardia, [Josué & Belloir] (49) 1036
AMYLASE, circulating, significance of, 385—E
ANAEROBES found in wounds, and mode of action in tissues, [Henry] (10) 242
ANAEROBIC methods, new, [Smilie] (60) 239
ANAPHYLAXIS: See also Immunity
ANAPHYLAXIS and primrose dermatitis, [Simpson] *95
  bacterial infection and, studies on, [Zinsser & Parker] (59) 1111
  fate of foreign proteins in acute anaphylactic reaction, [Manwaring & others] (78) 1297
  liver in shock and peptone poisoning, [Weil] (41) 1910
  lung phenomena in, 1352—E
  reactions to normal serums, [Leary & others] (14) 1826
  serum, serious forms of, in man, [Vermoni] (66) 948
  shock, rôle of hepatic tissues in acute anaphylactic shock, [Manwaring & Crowe] *722, (79) 1297
ANASARCIN and Anedemin, [Lapius] 1992—P
ANEDEMIN and Anasarcin, [Lapius] 1992—P
ANEMIA, blood lipoids in, [Bloor & MacPherson] (54) 314, 1176-E
  blood transfusion in, [Graves] (106) 943
  erythrocytes in, with elongated and sickle-shaped red corpuscles, [Emmel] (43) 1737
  from hemorrhage, lipemia in rabbits during, [Ellermann & Meulengracht] (83) 1306
  influence of splenectomy on metabolism in, [Denis] (15) 406
  oral sepsis and, [Graves] 2267—ab
  pernicious, etiology of, 43—E
  pernicious, in infant, [Bradley] (9) 549
  pernicious, transfusion and splenectomy in, [Minot & Lee] (46) 2148
  pernicious, treatment of, [Barker & Sprunt] *1919
  school, [Bracci] (58) 1571
  splenectomy in, [Haggard] *79
  splenic, critique of Banti's disease, [Moschcowitz] *1045
  splenic, splenectomy and omentofixation in, [Losio] (66) 2156
  splenic, surgery in, [Lockwood] (11) 593
ANESTHESIA and acidosis, relation between, [Caldwell & Cleveland] (113) 241
  apparatus, valve to regulate delivery of air and ether vapor in any proportion, [Gates] (58) 239
  blood pressure during, comparative study, [Miller] 403—ab
  effect of operation and, on kidney function, [Colp] (9) 67
  effects on blood volume and relation to production of shock, [Epstein] 403—ab
  ether, 302
  ether, and etherization in relation to infection and immunity, [Haines] 1734—ab
  ether, by rectal injection, [Montoya] (111) 499
  ether, effect on catalase in blood, [Burge] (3) 1735
  ether, effects of, and of visceral trauma as shown by vasomotor and blood pressure changes, [Muns] 404—ab
  etherization, perfected open, utility of, [Herb] 1734—ab
  ether-oil general, by rectum, [Protopopoff & others] (75) 857
  ether-oxygen, [Buettner] 1734-ab
  general, shock during, [Mann] *371
  improvised mask for, [Savariaud] (45) 2004
ANESTHESIA in curriculum and clinic, [Gatch] *367
  in orthopedic surgery, [Elmer] 404—ab
  in surgery of epileptics and control of status epilepticus, [Collier] 1735—ab
  in war surgery, 661, [Baruch] (35) 2153
  liquid air and electrolytic oxygen for [McLean] 1647—ab
  local, [Watson] 1734—ab
  local, of tonsils, simplified technic for, [Patton] *38
  lung complications following operations under, [McKeeson] 1647—ab
  nitrous oxid-oxygen, [Moots] 1646—ab
  nitrous oxid-oxygen analgesia and, in obstetrics, [Turner & Jones] 1734—ab
  nitrous oxid-oxygen, blood changes under [Casto] 1646—ab
  nitrous oxid-oxygen, comparative dangers and availability of, [McCurdy] 1647—ab
  nitrous oxid-oxygen, low pressure, nasal administration of, [Ecker] 1734—ab
  nitrous oxid-oxygen, with rebreathing in military surgery, [Boyle] (11) 2003
  tyramin as adjunct to morphin in labor, [Barbour] *882
  vapor, with reference to ether-oxygen, [Buettner] 1734—ab
ANESTHETICS, actions of, analyzed by observations of altered cardiac relations to calcium, [Burridge] (20) 72
  responsibility in choice of, 1104
  toxic factors of common anesthetic substances, [Graham] *1666
ANESTHETISTS, trained nurses as, and practice of medicine, 1731-Ml
ANEURYSM of basal arteries of brain, indirect trauma as factor in, [Hedinger] (74) 2075
  of left upper division of pulmonary artery; spirochete pallida in wall of artery and aneurysmal sac, [Warthin] (9) 1908
  traumatic diffuse, in surgical neck of humerus, [Knaggs] (2) 2151
ANGINA, Vincent's: See Vincent's Angina
ANILIN workers, tumors of bladder in, 204—E
ANIMALS, do they feel pain? [Van Rijnberk] (108) 1745
ANKLE joint, ankylosis of, [Ducroquet] (41) 2003, (36) 2211
  wounds of foot and, in war, [Quénu] (55) 321, (61) 1037
ANKYLOSIS, arthroplasty in, sphero of, [Thomson] (10) 1301
  of ankle joint, [Ducroquet] (41) 2003
  of elbow joint, arthroplasty for, [McKenna] *891
  surgical treatment of, [Olivieri] (62) 1571, (75) 1835
ANKYLOSTOMIASIS: See Uncinariasis
ANNALS of Medical History, 133
ANOMALIES of body, current, [Brachet] (30) 73
ANTHRAX, 2061—ab
  bacillus infection, hemorrhagic meningitis from, [de Jong] (79) 1572
  from shaving brushes, 396
  normal beef serum in, 1085-E, 1375, [Penna & others] (84) 1388, (60) 1571, (87) 2076, [Solari] (98) 1658, [Ligniéres] (95) 2076
  serum therapy, comparative inefficiency of, [Ligniéres] (72) 949
  suprarenal hemorrhage in, [Roger] (40) 759
ANTIARIN, electrocardiograms of frog heart under influence of, [Rümke] (114) 416
ANTIBLASTIC immunity, studies on, [Blake] (43) 1379
ANTIBODY and antigen in living animal, [Weil] (61) 150
ANTIFERMENTS in therapeutics, present status of, [Fernandez] (106) 159
ANTIGEN and antibody in living animal, [Weil] (61) 150
ANTIGONOCOCCUS vaccine in vulvovaginitis in children, [Condat] (26) 72
ANTIMENINGOCOCCI serum, standardization and administration of, [Amoss] *1137
ANTIPERISTALSIS, true, in small intestines, 1463
ANTIPNEUMOCOCCUS, Immune bodies, neutralization of, by infected exudates and serums, [Cole] (38) 1379
  serum, production of, [Cole & Moore] (42) 1379
ANTIPOLIOMYELITIS serum, production of, in horses, by inoculations of pleomorphic streptococcus from poliomyelitis, [Rosenow] *261
ANTIPYRETICS, effect of, on fever center, [Lüthy] (53) 2155
ANTIRABIC vaccine, 39
ANTISEPSIS, evaluation of asepsis and, [Fowler] (29) 1998
ANTISEPTICS: See also Disinfectants
ANTISEPTICS, irruption of, 2141—ME
  methods of applying, to deeper parts of wounds, [Kellock] (18) 1202
  of chlorin group, relative germicidal efficiency of, [Dakin & Dunham] (13) 2151
  specific for certain bacteria, [Taylor] (25) 2152

ARSENPHENOL-Amine Hydrochloride, 1695
  —Amine—S, 383
ARSPHENAMINE, 2115
ARTERIAL sounds, study of, [Roberts] *873
ARTERIOSCLEROSIS, etiology of, [Warfield] (66) 2149
ARTERY, brachial, pulse flow in, [Hewlett] (10) 406
  dry wounds of, 1019
  obstruction of, oscillometer in estimation of circulation after, [Balard] (47) 760
  popliteal, improved technic for ligation of, [Marinacci] (113) 677
  pulmonary, syphilis of, [Warthin] (9) 1908
  wounds of, in war, without external hemorrhage, [Alamartine] (44) 1654
ARTHRITIS: See also Gout; Joint Diseases; Rheumatism
ARTHRITIS, acute, of knee following injury, new pathogenic sporotrichum found in, [Wolbach & others] (47) 490
  and foreign protein, [Thomas] *770
  chronic, association of arterial hypertension with, [Swett] (13) 1109
  etiologic factors in gross lesions of large joints, [Clark] *2099

ARTHRITIS, gonococcal, antibodies in, after injection of specific and nonspecific protein, [Culver] (46) 1910
  oral sepsis and, [Gibbes] 2207—ab
  purulent, of knee, treatment of, [Van Vliet] (100) 2158
  rheumatoid, blood culture in, [Moon & Edwards] (62) 591
  rheumatoid, metabolism and successful treatment of, [Pemberton] (133) 1299
  syphilitic gastritis and, and febrile splenomegaly, [Verdozzi] (74) 1387
  traumatic, factitious, of knee, [Mori] (76) 247
ARTHROPLASTY in ankylosis, sphere of, [Thomson] (10) 1301
ASCITES from liver-heart disease in child under 3, [Martelli] (59) 761
ASCOLI succeeds Baccelli at Rome, 133, 300
ASEPSIS, evaluation of antisepsis and, [Fowler] (29) 1998
ASPHYXIA, behavior of thyroid in, [Pellagrin] (97) 498
  Gas: see Gas Asphyxia
  influence of, on rate of liberation of epinephrin from suprarenals, [Stewart & Rogoff] (85) 315
  traumatic, [Sherrill] (114) 408
ASPIRIN: See Acid, Acetyl-Salicylic
ASSOCIATION of American Medical Colleges, requirements for admission, 552—E
  of Military Dental Surgeons, 925
  of Military Surgeons, meeting of, 578, 1013
ASTHENOPIA, chronic headache from, [van der Brugh] (93) 1208
ASTHMA, alveolar air in, 827—E
  bronchial, cause and treatment of, [Walker] *363
  bronchial, nonpassive expiration theory of, [Brown] (108) 671
  bronchial, reactions incidental to treatment of 2 cases, [Rackemann] *889
  bronchial, subcutaneous injections of proteins to which patients are sensitive in, [Walker] (51) 490
  bronchial, treatment with bacterial vaccines of asthmatics not sensitive to proteins, [Walker] (106) 1199
  bronchial, vaccination in, [Sicard] (8) 67
  bronchoscopy in, [Symes] (18) 493
  experimental, in guinea-pig, [Sewall] (74) 1472
  traumatic, [Losper & Codet] (63) 1478
ASYSTOLY, limits of, [Perrin] (67) 1656
ATAXIA, inherited, [Massalongo] (93) 497
  Locomotor: See Tabes Dorsalis
ATHLETE, heart of, [Heitz] (24) 1831
ATHYREOSIS, fetal 43—E
ATOPHAN, 1971
ATROPIN and amyl nitrite test in *bradycardia*, [Josue & Belloir] (49) 1036
AURICULAR Fibrillation: See Heart
AUSCULTATION through mouth, [Notari] (51) 1118
AUSTRALIA, death rate and invalidity in, 2085—ab
AUSTRIAN physicians decide for conscription, 1552
AUTOMOBILE accidents in New York, 2010—ab
  as instrument of death, 775—ab
AUTOPSY: See Necropsy
AUTOSEROTHERAPY: See Serotherapy
AVIATION and ear, [Jones] *1607
  equilibrium tests for recruits, [Small] *1078
  physical effects of, [Schurmeier] 584
  sickness caused by, [Ferry] (35) 854
AVIATORS, medical, honors for, 838
AYER, J. C., Company and open formula, 1554—P

B

BABY clinic, model, 837
  week, 396
BACILLUS abortus bovinus in certified milk, presence of [Fleischner & Meyer] (1) 1028
BACILLUS abortus, lesions attributed to tubercle bacillus possibly caused by, 1879—E
  acid-fast organisms in distilled water, problem of, [Keilty] (115) 1199
  aerogenes capsulatus, antitoxin for, prophylactic and therapeutic properties of, [Bull] (45) 1379
  aerogenes capsulatus, hemolytic substances in heated milk and milk cultures of, [Ford & Lawrence] (18) 670
  aerogenes capsulatus, toxin and antitoxin of, and inoculation against, [Bull & Pritchett] (66) 239
  bronchisepticus, lesions produced by injection into renal artery, [Winternitz & Quinby] (77) 151
  Carriers: See under names of diseases
  coli, and paratyphoid B bacillus, comparative resistance of, in drinking water, [Dauméxon] (23) 1301
  coli, isolated from pyelocystitis cases, fecal lesions produced in rabbits by, [Helmholz & Beeler] 147-ab, (1) 311
  coli-hemolyticus, cystitis caused by, [Lyons] *1342
  diphtheriae, morphology of strain of, [Heinemann] (41) 670
  mucosus capsulatus, production of acute and chronic kidney lesions with, [Major] (111) 1199
  Tuberculosis: See Tuberculosis
  typhi-exanthematici, development of antibodies for, in typhus contacts, [Baehr] (59) 591
  Typhoid: See Typhoid Bacillus
BACTEREMIA, chronic, transfusion of immunized blood in, [Wekesser] *2182
  in lobar pneumonia, [Sutton & Sevier] (21) 1648
BACTERIA and vitamins, 1531—E
  nucleoproteids, [Ferrannini] (49) 596
  obsidional, pathologic manifestations of, [Sacquépée] (37) 1653
  persistence of, within sequestrums, [Taylor & Davis] (20) 1998
  staining, acid polychrome-methylene blue solution for routine and special staining, [Goodpasture] *998
BACTERIOTHERAPY: See Vaccine Therapy
BACKWARDNESS: See Feeblemindedness
BALANITIS, erosive and gangrenous, [Owen & Martin] (72) 1472
  gangrenosa, [Pusey & others] *1080
BALANTIDIUM coli in Argentina, [Parodi & others] (82) 1479
BALDWIN CAYUGA Mineral Water misbranded, 1901—P
BANANA, 1972—E
  as food for children, [Pease & Rose] (5) 1825
BANTI'S DISEASE: See Anemia, Splenic
BÁRÁNY'S sign in epileptics and schoolchildren, [Tracy] (87) 70
  tests in diagnosis of vertigo from whatever cause, [Jones] *812

BEEF serum, toxicity of normal, [Sordelli & Fischer] (83) 323
BEER as source of protein, 1265—E
BELGIAN and French physicians, aid for, [Keen] 228—C, 665—C, 829—E, 1268—E, [Keen] 1290—C, 1728—C, [Jacobs] 2063—C
BELL-ANS (Pa-pay-ans Bell), 1815—P
BENCE-JONES proteinuria, 824—E
BERETTA prize for Milan physicians, 1720
BERIBERI, blood in, [Yoshikawa & others] (17) 406
  differential leukocyte count in, [Chun] (19) 2003
BETANAPHTHOL Benzoate, 821
  Benzoate-Calco, 821
BIBLE, surgical and medical incidents in, 1291
BIER'S method of passive hyperemia in trench feet and allied conditions, [Turner] (16) 1913
BILE and feces of cholera cases and carriers, bacteriologic investigation of, [Crowell & Johnston] (95) 1565
  derivatives, influence of, on Bloor's cholesterol determination, [Luden] (64) 2149
  duct, common, cyst of, [Waller] (80) 598
  ducts, congenital obliteration of, [Comby] (13) 1115
  influence of, on phenol production, [Dubin] (63) 311
  is it a cholagogue? 386—E
  retention of, [Segura] (80) 1207
  tract, recurrence after operations on, [Eisendrath] *1752
BILHARZIOSIS, [Diamantis & others] (44) 1381
BILLINGS, Dr., in Russia, 918
BIOCHEMICAL investigations on blood and urine, bearing on clinical and experimental medicine, [Folin] *1209
BIOLOGY, medical, society for research on, 1188
BIRTH RATE, declining, [Maurel] (38) 1568
  rate, low, in Ireland, 1372
  returns and war, [Chalmers] 610—ab
BISMUTH and nitrite poisoning from use of bismuth subnitrate, 3 cases, [Phillips] (11) 239
  iodoform paste in outpatient work, [O'Conor & Kreutzmann] *2010
BITTER tonics, [Carlson] 33—ab
BLADDER, action of alypin, eucain, holocain, novocain and stovain on, [Waddell] (73) 1738
  calculi, clinical study of, [Bugbee] *1492
  calculi incidence of phosphatic urinary calculi in rats fed on experimental rations, [Osborne & others] *32
  calculus, large, [Browne] *1686
  cancer, [Gardner] (135) 316
  cancer of prostate and, radium in, [Barringer] (18) 1378
  cystoscopic examination of in psychoses, [Barnes & Caulk] (76) 942
  disturbances due to nerve lesions, [Smith] *1323
  diverticulum, report of 2 cases, and operative technic, [Lewis & Moore] *1334
  drainage tube in first stage of suprapubic prostatectomy, [Ballenger & Elder] *2104
  exstrophy of, treatment of, [Mayo] *2079
  exstrophy of, with report of transplantation of entire bladder and ureteric openings into sigmoid, [Haggard] (84) 1912
  fistulas of vagina and, inaccessible, operative treatment of, [Ward] (104) 593
  noncatheterization of urinary bladder in cases of gunshot wound of spinal column, [Besley] *638
  purpura affecting, [Perrier] (41) 1117
  syphilis of, [Fowler] *1399
  tumors in anilin workers, 204—E
  tumors, nonoperative treatment, [Braasch] 1823—ab
  tumors of urinary, [Judd] 2066—ab
  tumors, operative treatment for, [Fedoroff] (87) 1207
  tumors, results of treatment of, [Geraghty] *1336
  wounds in war, [Legueu] (43) 1384
BLIND sailors and soldiers, 928
  welfare of, 928
BLINDNESS: See also Ophthalmia Neonatorum
BLINDNESS, causes of, 928
  pretended deafness and, detection of, [Keiper] (24) 2069
BLOOD, action of elements of, on vessels, [Yamamoto] (74) 1572
  albumoses in tissues and, with reference to occurrence in gastro-intestinal mucosa, [Abel & others] (6) 1735
  alkali reserve of, decreased, relation of epinephrin hyperglycemia to, [Peters & Geyelin] (70) 850
  ammonia in urine and, in acidosis, [McNeil & Levy] (47) 1910
  and tissue spaces, factors influencing interchange of fluid between, [Scott & others] (4, 5) 1735
  arterial, effect of accumulation of carbon dioxid on *tidal* air and H-ion concentration of, in decerebrate cat, [Scott] (10) 1294
BLOOD, biochemical investigations of urine and, bearing on clinical and experimental medicine, [Folin] *1209
  calcium and magnesium in serum, micromethod for determination of, [Marriott & Howland] (87) 2000
  calcium and tetany, toxicity of phosphates in relation to, [Binger] (65) 942
  calcium in, determination of, [Halverson & Bergeim] (83) 2000
  calcium in serum in pathologic conditions, [Halverson & others] (84) 2000
  calcium, studies in, [Cowie] 147—ab
  carbon dioxid of, and pulmonary ventilation, 1789—E
  catalase in, effect of ether anesthesia, emotions and stimulation of splanchnics on, [Burge] (3) 1735
  chloride in, modification of McLean-Van Slyke method of determining, [Foster] (86) 1198
  cholesterol content of human, [Gorham & Myers] (41) 1737
  cholesterol estimations in, 1975—E
  circulating and stationary, [Prével] (40) 1833
  coagulating property of, index for, [Fonio & Schulsinger] (72) 157
  coagulation index of, [Hitce & Iribarne] (91) 1120
  coagulation, studies in protein intoxication, [Shattuck] (20) 848
  composition, effect of dextrose intravenously on urinary secretion and, [Davis] (15) 238
  corpuscles, diluting fluid for counting, [Diner] *1421
  corpuscles, polychrome stain for protozoa and, 1024
  corpuscles, red, conditions affecting formation of, 2042—E
  corpuscles, red, in severe anemia with elongated and sickle-shaped red corpuscles, [Emmel] (43) 1737
  corpuscles, red, normal shape of mammalian, [Arey] (4) 2146
  corpuscles, stain for protozoa, and, [Watabiki] (139) 679
  corpuscles, variations in resistance to hemolysis, [Rhamy] 1728—C
  Corpuscles, White: See Leukocytes,
  counts, complete, analysis of 998, [Utley] (84) 2071
  creatin and creatinin in, 648—E
  destruction, relation of spleen to blood regeneration and, and to hemolytic jaundice, [Goto] (56) 2149
  determining iso-agglutinin group, priority for simplified method of, [Williamson] 486—C
  diastatic activity of, in diabetes, 385—E
  distribution of, effects of epinephrin on, [Gunning] (12) 1294
  effect of trinitrotoluene on, [Panton] (58) 674
  granulation of, in malaria, cause of, [Hirschfeld] (49) 1118
  in irritable heart, bacteriologic examination of, [Dimond & Briscoe] (4) 1033
  in lungs, 1614—E
  in surgical shock, hemoglobin value of, [Bainbridge & Bullen] (55) 494
  inorganic *phosphates* in serum, micromethod for determination of, [Marriott & Haessler] (88) 2000
  lancet, new, [Stein] *383
  lipoids in anemia, [Bloor & MacPherson] (54) 314, 1176—E

AUTHOR INDEX

In this Index are the names of the authors of articles which have appeared in The Journal, the names of those who have read papers before Societies as published in The Journal and those whose articles have been abstracted in the Current Medical Literature Department. The * preceding the page reference indicates that the article appeared in full in The Journal. The number in parentheses indicates the numbered paragraph on the page referred to. The numbers not in parentheses indicate pages. The author's name is followed by a brief clue to the subject of the article in brackets.
